A re-location of a claim located by another admits the validity of the original location. In an action to quiet title to a mining claim, where the complaint set forth an affidavit of assessment work done by defendants at a certain time but alleged that the defendants had abandoned the claim, and the answer denied the allegations of abandonment, a prima facie case was made in favor of the defendants, even though their answer did not aver that they were in actual possession at the commencement of the action.

Betsch v. Umphrey (Alaska), 252 Federal, 573.

Miner's Liens—Owner's Interest

The holder of an option contract to purchase mining claims, with permission, during the life of the option, to occupy and work the same at his own expense, upon condition that he return to the owner a specified portion of the profits, is a lessee during occupancy of the property. The owner's interest in the mining claims is not, under the laws of Idaho, made lienable for work done at the instance of his tenant, unless, by some additional act, understanding or arrangement he causes the work to be done or makes the tenant his agent

Nicholson v. Smith (Idaho), 174 Pacific, 1008

Excess Placer Location—Rights of Locators

A placer location, made in good faith, but containing by mistake an excess area, is void as to the excess which may be rejected from such portion as the owner may select after reasonable notice of the mistake in area.

Where a locator attempted to initiate a new location within the limits of such an existing placer claim which contained an excess area, without notifying all of the co-owners of said placer so as to give them an opportunity to cast off tho excess, he was a mere trespasser and acquired no rights by his attempted location.

Adams v. Yukon Gold Co. (Alaska), 251 Federal, 226.

Public Lands—Jurisdiction During Patent Proceedings

The public lands being under the control of the Land Department, including a bureau headed by the Commissioner of the General Land Office, to whom, as a special tribunal with quasi judicial powers, Congress has confided the execution of laws for the sale and disposal of public lands, where a patent for mineral oil-lands has been applied for and charges of fraud are under investigation, pending action upon the application, the courts are without jurisdiction to determine the rights of claimants in possession as against the United States. Receivership applied for by the Government refused.

Devils Den Consolidated Oil Co. v. United States (California), 251 Federal, 548.

Injury to Surface Defined

The right of support is vital to the overlying surface and strata. Therefore it is not presumed to have been given up unless expressly or by strong implication. The word "surface" in mining controversies means that part of the earth or geologic section lying over the minerals in question, unless the contract or conveyance otherwise defines it. It is not merely the top of the glacial drift, soil, or the agricultural surface. Clause in the deed granting coal rights, providing that the grantee shall not enter upon or injure the surface construed as prohibiting them from letting down the surface through removal of coal pillars, including the word "surface" plaintiff's cement deposits which overlay defendant's coal seams. Injunction awarded.

Marquette Cement Mining Co. v. Oglesby Coal Co. (Illinois), 253 Federal, 107.

Potash production of the United States last year, according to W. B. Hicks of the U. S. Geological Survey, was as under:

Sources	Number of producers	Production, tons	Available potash (K_2O), tons
Natural brines	21	117,125	39,255
Alunite	4	6,073	2,019
Dust from cement mills	9	11,739	1,429
Kelp	6	11,456	4,292
Molasses distillery waste	4	9,505	3,322
Steffens waste water	5	2,818	761
Wood ashes	26	609	305
Other sources	3	262	92
	78	192,587	52,135

The output in 1918 was almost double that of 1917, and is 22% of normal domestic consumption. The brines of Nebraska yielded 55% of the total.

Graphite (domestic) sales during 1918 totaled 6500 tons, valued at $1,500,000, compared with 5292 tons and $1,094,398 in 1917. About 4400 tons was of the No. 1 and 2 flake grades.

Book Reviews

Steam Engines. By E. M. Shealy. Pp. 286, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, $2.50.

The author is associate professor of steam engineering at the University of Wisconsin, and the book is written primarily as a textbook for students, but it will also be of value to the operating engineer who wishes to increase his knowledge of the technical side of the subject. The book is almost entirely devoted to reciprocating engines, turbines being discussed in the last chapter only, and then very briefly. The first chapter considers elementary principles, also the plain slide-valve engine, and this is followed by a discussion of Corliss engines, locomotive engines, and marine engines. The book is well illustrated and is as nearly non-mathematical as is possible, considering the subject.

Organic Compounds of Arsenic and Antimony. By Gilbert T. Morgan. Pp. 376, index, bibliography. Longmans, Green & Co., New York, 1918. For sale by 'Mining and Scientific Press'. Price, $4.80.

The study of organic arsenical and antimonial compounds has extended from early times, and has received the careful attention of chemists for more than 200 years. These substances, apart from the fact that most of them are highly toxic, are of special interest from their therapeutic value. The selective action of many of them permits their use in combating various diseases resulting from protozoal parasites. Atoxyl has proved useful as a remedy in sleeping sickness, and neosalvarsan has supplied a means for combating some of the serious contagious diseases that afflict mankind. The work by Dr. Morgan is a highly-technical discussion of the typical compounds, cacodyl, alipathic arsenicals and antimonials, aromatic arsenicals, atoxyl, salvarsan, neosalvarsan, aromatic antimonials, hydro-aromatic derivatives of arsenic and antimony, heterocyclic rings containing arsenic and antimony, arsenical esters and arsenical lipoid and protein combinations. Methods of preparation and characteristic reactions of the compounds are given in detail.

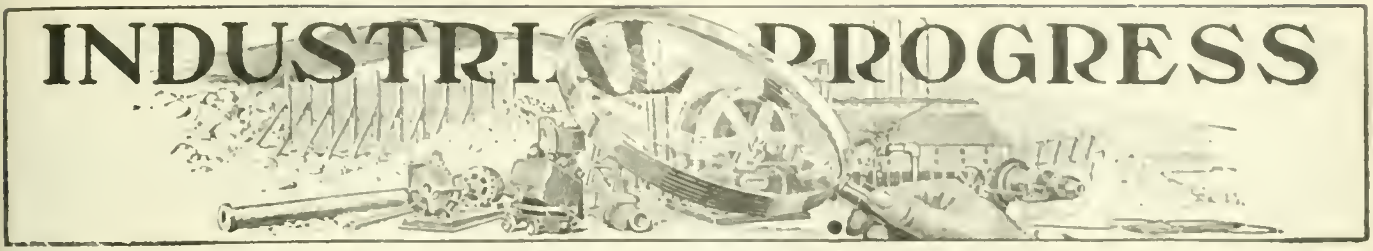
Storing. Its economic aspects and proper methods. By H. B. Twyford. Pp. 200, ill., index. D. Van Nostrand Co., New York, 1918. For sale by 'Mining and Scientific Press'. Price, $3.50.

The author of this book has also written on a kindred subject, namely 'Purchasing'. He is connected with the Otis Elevator Co., so should be fully conversant with storage methods. From a number of manufacturers of storeroom equipment he has obtained data and illustrations on the subject, so that it would seem as if the work before us should be thorough. In the 12 chapters are covered the economic questions connected with storing material, the location and equipment of storeroom, appliances used, manual and clerical work, the storekeeper, receiving, inspecting, and placing material, and deliveries. A few pertinent remarks from the book are suggestive: "Into every form of commercial activity which involves the retention for long or short periods of materials and supplies is penetrating the new importance of storing." "Every business needs a certain amount of raw material or manufactured articles, or supplies. For successful operation there must be sufficiency, and there must not be lack." "Too often the storekeeper is looked upon as a man whose duties are exclusively physical. He is not supposed to have a thinking job. The position of storekeeper needs better recognition; it needs recognition on a somewhat different basis to that which is usually accorded it. Sufficient consideration has not been given to the potentialities of the keeper of the stores. He is in complete control of a very large proportion of the wealth of many concerns." "Buying and storing, although distinct and separate functions in any business, are closely related in all those cases where the goods do not immediately pass out of the possession of the purchaser." "It is essential that stock in storerooms be properly described and designated." And "Nothing should be permitted to enter the storeroom unaccompanied by some form of advice . . . no material should be allowed to leave the stores without a properly drawn requisition." The many duties of store employees are fully discussed, and the illustrations show how stocks should be arranged, handled, and counted. Many companies will find this book worth-while when on their storekeepers' desks.

Metallurgy of the Non-Ferrous Metals. Second edition, revised and enlarged. By William Gowland. Pp. 588, ill., plates, index. Charles Griffin & Co., London, 1918. For sale by 'Mining and Scientific Press'. Price, $8.50.

Having no copy of the first edition of this work we are unable to make comparisons, but from a preliminary perusal we find the book before us to be one of much value. Alphabetically, the metals considered are aluminum, antimony, arsenic, bismuth, cadmium, cobalt, copper, gold, lead, mercury, nickel, platinum, silver, tin, and zinc. And thinking over the latest metallurgical practice for these metals, we find that the author has as much as is possible to procure on aluminum, although his statistics are rather behind; the notes on antimony include the liquation and the preferred process of volatilizing-roasting and reduction of the oxide to metal; the American system of recovering arsenic, as in the Washoe works at Anaconda, is included; those having bismuth in their ores will find the eight pages of value, as little is available otherwise; as cadmium is a by-product of zinc, and is comparatively rare, the two pages given are sufficient; the new use of cobalt in the alloy 'stellite', and in electro-plating, also its recovery from Cobalt, Ontario, silver ores, is covered; copper is dealt with in 114 pages, wherein is described roasting, smelting, converting, leaching by ammonia and sulphuric acid, and electrolytic refining; the 136 pages on gold cover all phases of milling with the most modern machinery, cyanidation, and refining; in 68 pages lead is considered, including the Bunker Hill & Sullivan and Trail works, but the Morse system of open tops to furnaces, as at El Paso, is rather too recent for inclusion; in the chapter on mercury some of the new work being done at Idria and Almaden and by the State Mining Bureau of California is described, although the rotary type furnace is not mentioned, being rather recent; the complex processes for recovery of nickel as at Sudbury are described; the note on preparation of pure platinum is useful; in the 51 pages on silver we note the latest processes in Ontario, Nevada, and Mexico, although the sodium-sulphide precipitation method is omitted; tin-smelting practice in Cornwall, Germany, New Jersey, the Straits, and Tasmania is detailed, also the recovery of tin from scrap; and lastly zinc includes distillation, electrolytic extraction, and smelting from ores. Besides the metallurgical notes, each metal has its physical and chemical properties stated briefly, also its ores, alloys, and uses. Ahead of all chapters on the metals are 12 pages on refractory materials, 29 pages on roasting principles and furnaces, and 6 pages on fluxes and slags. There are 217 illustrations, mostly of modern plant. The Cottrell precipitator is dismissed rather too briefly, and flotation is hardly mentioned. Statistics are mostly of 1913 or 1914, of course showing normal production, yet later data are available. A few typographical errors and peculiar style for terms are noticeable, but the work is probably the best reference extant on the non-ferrous metals. M. W. vB.

INDUSTRIAL PROGRESS



INFORMATION FURNISHED BY MANUFACTURERS

MINE SECTION-INSULATOR WITH SWITCH

By N. A. Wahlberg

In mines, every cross-entry should have a section-insulator fixed in the cross-entry trolley-wire on tangent as close as possible to the main entry. As most cross-entry trolley-wires are used only a small part of the time, it would increase the safety if the voltage were cut-off when not in use.

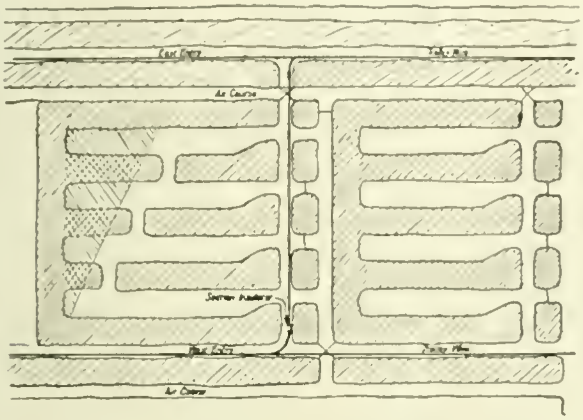


FIG. 1. MINE LAY-OUT WITH SECTION-INSULATOR.

Fig. 1 shows a coal-mine lay-out in line with Eastern practice, with section-insulators at each end of the cross-entry connecting the east entry with the west entry. A common practice is to use a section-insulator similar to Fig. 2. This type of insulator has no switch attachment, and it is necessary to have a knife-switch connected in the circuit so that the cross-entry trolley-wire can be energized, as in Fig. 3. The knife-switch should be mounted in a box to protect same from moisture and dust. It is readily seen that this arrangement requires considerable amount of labor and material. It also has its disadvantages, as the locomotive may get stalled with the trolley-wheel on the insulated part of the section-insulator when the locomotive is pulling a load. Considerable delay will be experienced in case there is insufficient room to turn the trolley-pole, and it is often necessary to detach several cars to enable the locomotive to get over the dead section in the overhead.

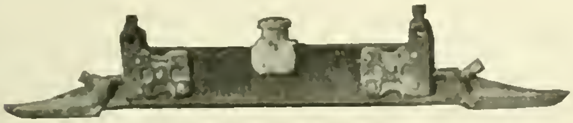

FIG. 2

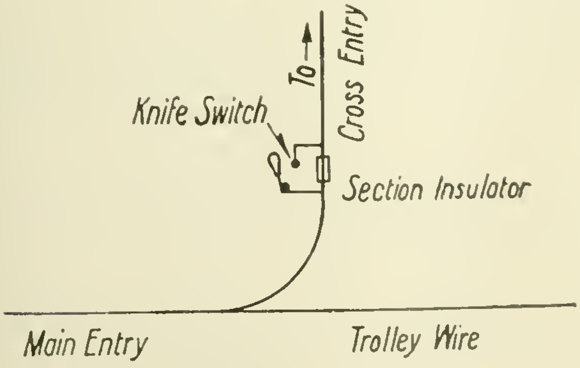

FIG. 3

Mine operators have demanded a combination of section-insulator and knife-switch that would eliminate delays of this nature in their haulage service, and the section-insulators designed by the Westinghouse Electric & Mfg. Co., illustrated in Fig. 4 and 5, have proved successful in a number of installations.

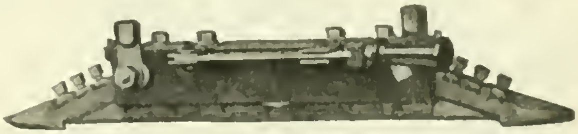

FIG. 4

A section-insulator should not permit of any leakage whatever if the switch is open. Its construction, as a whole, should be mechanically strong, yet not too heavy to add any unnecessary weight in case the local conditions are such that it cannot be supported direct by means of suspensions from the mine-roof. Two supporting lugs with longitudinal adjustment are preferable, as in Fig. 4. Where conditions do not permit of using two supports and space is limited, a swivel-boss in the centre is desirable, as section-insulator can be easily put up without turning the complete section-insulator, as in Fig. 5. The runner of the switch should never obstruct the passage of the trolley-wheel, regardless as to whether switch is open or closed.

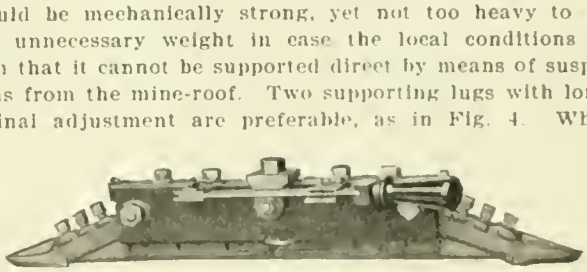

FIG. 5

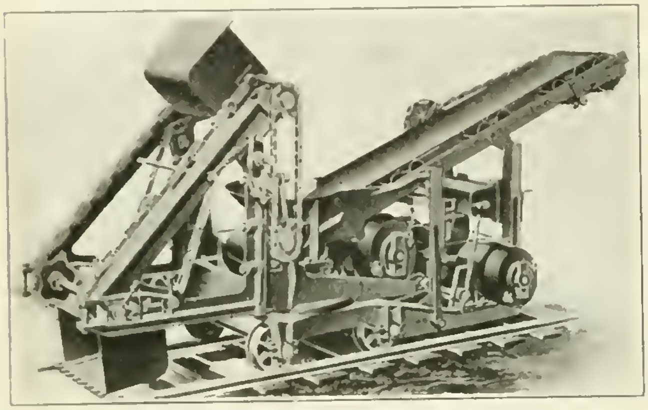
A metallic runner with air insulation has several advantages. It allows uniform wearing and no parts require renewal; for instance, where treated wood or fibre is used, see Fig. 2, considerable arcing when breaking the circuit takes place, eventually increasing to such an extent that the runner parts have to be replaced frequently. The switch should be independent of the runner, and of such section that it will permit a heavy current to pass through without heating the section-insulator at any point, as this may damage the insulation qualities of the section-insulator.

Direction of feeding in a mine varies, and a switch should be made so that it can be opened either right or left hand. Fig. 5 shows a switch that can easily be converted to right or left hand by loosening the machine bolts and interchanging the break-jaws with the hinge-jaws. Changes of this nature can easily be made in the mine. When the switch is open, the break-jaw should always be the live terminal, this can be accomplished by interchanging the hinge and break-jaws as mentioned above.

A CONTINUOUS TWIN-SCOOP LOADER

After several years of development, the Wellman-Seaver-Morgan company of Cleveland, Ohio, has placed upon the market a mine loading-machine known as the McDermott continuous twin-scoop loader. As its name implies, this machine digs loose ore, dirt, or muck, by a continuous scooping process. The material is picked up by scoops or buckets on an endless chain, elevated and dropped into a hopper, which feeds a conveyor-belt, in turn loading a car. The accompanying illustration shows these points. The scooping mechanism is so pivoted that it can dig to the side as well as in front of the machine. The ore, however, being delivered to the conveyor through the hopper, reaches the car behind the loader, irrespective at what angle the scoop is working. The movement of the scoop is continuous, not reciprocating. The machine is self propelled, and is so designed that it can easily be transferred about a mine. It will load at the rate of over 1 ton per minute, and may be operated by unskilled labor. In designing this machine, the adverse conditions and restricted space underground have been kept in mind, and particular attention has been given to rigidity with minimum weight. While specially designed for underground work, the loader is not limited to this, as it can also be used on the surface for loading coal from piles to cars, removing piles of rock and sand, and similar operations.



THE CONTINUOUS TWIN-SCOOP LOADER.

The loader consists of three main parts, truck, digging-head, and conveyor. These parts can readily be dismounted and as readily re-assembled, permitting ease of handling in getting the machine underground and in moving from level to level. The levers are at one side, in a position convenient for the operator to watch the various movements.

The loader is fitted with motors wound for 230 volts, d.c., providing power for all of the operations. The motors are of the entirely enclosed type. All chains and gears are protected. All chains are provided with take-ups, and the digging-edge of the bucket is fitted with renewable tooth sections. The entire frame-work is of steel, the digging-head is mounted on a large ball-bearing, and all parts are protected as much as possible against dirt and water.

The general dimensions of the loader are: Maximum over-all length, 15 ft. 9 in.; height, with buckets in lowest position, 5 ft. 6¾ in.; height, when machine is in operation, 6 ft. 7½ in.; width, 4 ft.; gauge of truck wheels, 24 in.; maximum rated capacity with full buckets, 1.75 tons per min.; average capacity, 45 tons per hour; and weight of complete machine, 8000 pounds.

From the illustration will be seen the difference between this and other mine loading machines.

COMMERCIAL PARAGRAPHS

Catalogue No. 7 of the **Hardinge Conical Mill Co.**, New York, in 5 sections, covers its ball and pebble-mills.

Paint and varnish dealers will be interested in a new pamphlet just issued by the paint and varnish department of the **Du Pont Co.** of Wilmington, Delaware, on mill and mine paints. It describes a line especially designed for the painting and up-keep of machinery, equipment, factory and mill buildings.

The American Manufacturers Export Association has been organized by 1100 of the leading manufacturers of the United States, and will collect and issue news of interest to exporters. The head office is at 160 Broadway, New York, with S. J. Quinn as secretary. Well-known industrial men are among the directorate.

At the annual meeting of the **Wellman-Seaver-Morgan Co.** at Cleveland on February 18, the retiring directors were re-elected. The following officers were elected: Edwin S. Church, president and general manager; S. G. Pitkin, vice-president; G. W. Burrell, second vice-president; and W. H. Cowell, secretary-treasurer. Mr. Burrell has been in the continuous employ of the company for 21 years. He will have entire charge of the works at Cleveland and Akron.

The proper caustic soda to be used with Proto Fleuss self-contained breathing-apparatus is especially prepared for **H. N. Elmer of Siebe, Gorman & Co.**, Chicago, by the Mendleson Corporation. This is put up in 4-lb. cans in 24-can crates, and labeled, and is the only soda, except c. p. stock soda, to be used with the Proto apparatus. The lump caustic soda is sold by the Mendleson Corporation of Albany, New York, at 12 to 15c. per lb. for 2016 to less than 480-lb. lots.

The Material-Handling Machinery-Manufacturers' Association was formed recently at the suggestion of the Department of Commerce and the U. S. Shipping Board, and offices have been opened at 35 West 39th street, New York. The work of the Association will be similar to that of most trade organizations, except that more extensive technical committee work will be required than is usually the custom. There is one aspect of the work that is unusual. Other trade organizations will be asked to appoint material-handling committees which will meet with committees appointed by the new Association to consider the special handling problems of each particular industry. The officers of the Association are Calvin Tomkins, president; J. A. Shepard, vice-president; Zenas W. Carter, secretary and manager; Lucian C. Brown, treasurer; J. A. Shepard, Lucian C. Brown, R. W. Scott, F. W. Hall, William Clark, J. C. Walter, C. M. Watson, and F. Stadelman.

The Heine Safety Boiler Co., of St. Louis, Missouri, has issued the latest edition of its 'Boiler Logic', an 86-page treatise on steam boilers. The following topics are covered:

I. 'Some Fundamental Considerations of Boiler Design': (a) Furnace design requirements: Mixing, time, temperature; (b) heat transmission from fire by radiation; (c) heat transmission by convection; and (d) heat transmission through tubes and to water.

II. 'Practical Baffling of Water-Tube Boilers': (a) Flexibility of design; (b) leakage and cost of repairs and renewals; (c) active and inactive surface; and (d) ease of cleaning soot and ash deposits.

III. 'Heine Boilers for Different Fuels, Firing, and Services': including hand firing with bituminous coal, shavings, and refuse; hand firing with anthracite coal and bagasse (sugar-cane residue); chain-grate and underfeed stokers; oil-fired, gas-fired, waste-heat, and dredge boilers.

IV. 'Overloads'.

V. 'The Boiler as a Pressure Vessel'.

VI. 'Details of Construction of Heine Boilers'.

EDITORIAL

ALTHOUGH we are passing through a period of readjustment, the signs of prosperity are visible to anyone but a confirmed pessimist. Bank clearings are big, the railroads are carrying an enormous tonnage, insolvencies are comparatively few, our foreign trade is beating the record. It is true, food is dear and wages are high, so that the cost of living is excessive, but the dearness of food and labor is due largely to the inefficiency of the latter, not to excessive pay. These matters are being arranged by the incorrigible ratio of supply and demand.

ONE of our local organs of misinformation told its readers a few days ago that the Butte & Superior Mining Company had reduced its working force 50% on account of the over-production of copper. We suppose that the words 'Butte' and 'Superior' suggested copper, but the fact is, as our readers are aware, that the Butte & Superior, although originally organized to mine copper ore and formerly called the Butte & Superior Copper Company, now produces zinc and silver, with a little lead, and we hope that it will continue to produce all of them for many years to come, profitably.

WITH this issue we publish a review of Josiah Royce's book on the early days of California by our friend Mr. Grant H. Smith, himself a native of Sutter Creek, one of California's earliest mining settlements. Mr. Smith is a lawyer by profession, but his boyhood was spent among the mines, so he is able to interpret sympathetically not only Royce but the frontier life of which Royce writes. Here we give ourselves the pleasure of acknowledging that we have found it advantageous, more than once, to make use of Mr. Grant Smith's fine feeling for our language, the language of Shakespeare, of whom he is an affectionate student.

IN the Internal Revenue Act for 1918 is included a stipulation exempting gold-mining enterprises from the excess-profit tax. This may be taken as one result of the good work done by the Committee on Gold, of which Mr. Hennen Jennings was chairman. The idea that mining for gold profited from the War is absurd, of course, because even under ordinary conditions the 'price' of gold would not be directly affected, whereas it is a fact that the abnormal financial conditions produced by world-wide belligerency did have the effect of depreciating the standard metal. If this exemption had not been made the owners of many gold mines, especially those coming into production for the first time during the War, after years of expensive development, would have fared very badly. We are glad therefore to note that the excess-profit tax is not to be added to the burdens of the gold miner. This exemption should draw the attention of legislators and financiers to the peculiar position of gold in world economics and stimulate study of a subject that is of compelling importance.

REPORTS from Europe indicate that there will be a good market for American copper in the near future. Orders from several sources, with France as the principal buyer, are promised. Second-hand and speculative holdings of copper are said to be undergoing rapid reduction through purchases made by domestic consumers, making way for the re-establishment of a normal market. Some of the copper companies may have to borrow money in order to carry their stocks of metal, as, for instance, was done recently by the Kennecott Copper Corporation, which borrowed $12,000,000 to protect the 55,000,000 pounds of copper it was carrying, but this can be done without serious financial injury because of the inherent soundness of the copper-mining business. Conditions will readjust themselves slowly. There is no cause for panic.

IT is reported that at the conference of Governors and Mayors held at Washington on March 5 an attempt to invite the meeting to endorse the Government ownership of railroads was defeated by acclamation. This expression of opinion, we believe, represented the feelings of the public at large. Not only is the present administration of the railroads costly and inefficient, as compared with the management of the companies owning the railroads, but most thoughtful citizens will appreciate the great danger of expanding the political machine and aggrandizing the patronage of the party in power at Washington. This refers to both parties, of course. No non-partisan democrat can contemplate without uneasiness the continued growth of bureaucratic organizations at the capital.

THOSE who are concerned with the winning of oil, and everybody desiring to be well informed, will find something to interest them in the article, appearing in this issue, by Mr. J. H. G. Wolf, who has made a special study of the problems, technical and economic, arising from the exploitation of our oil resources. He recites the course of the market for petroleum products during the War and shows how hard this industry was hit by the general dislocation of trade, but the chief feature of his article is a lucid explanation of the manner in which the flow of oil is regulated by the pressure of the gas that constitutes an integral part of such natural deposits. This gas-pressure gives the impulse necessary for collecting and impelling the oil to the surface and it comes into active play just as soon as an opening is made by a bore-hole or well. During periods of non-production, when operations cease for any reason, this valuable force is dissipated, so that the human effort to win the oil has to be increased. This fact should govern the selection of the time and place for drilling new wells, as Mr. Wolf's statistical summary shows conclusively.

EFFORTS are being made to persuade the Secretary of Commerce in the Mexican cabinet to call a general meeting, at Mexico City, of mine operators in the four northern States for the purpose of discussing the welfare of the mining industry and the settlement of important questions arising out of the conditions created both by the European war and the domestic revolution. A scarcity of explosives is said to be crippling mining operations and the imposition of excessive taxes is menacing the stability of the industry. It is hoped that President Carranza, who is seeking financial aid in New York, will realize the need for dealing fairly with those who are engaged legitimately in the production of metals and of oil in Mexico.

WE have received a telegram from Mr. J. E. Spurr, of the War Minerals Investigation Committee of the U. S. Bureau of Mines, stating that the President has signed the War Minerals Relief Act, providing for the adjustment of war claims on account of the production of manganese, chrome, tungsten, and pyrite during the period of the War; and that settlement of such claims is to be made at the discretion of the Secretary of the Interior; therefore it will become necessary to examine a large number of mines in order to ascertain the validity of the claims. The Bureau of Mines invites applications, for appointment as inspectors for this purpose, from mining engineers of the requisite standing, judgment, and experience. Salaries will range from $300 to $400 per month and it is probable that the engagement will cover a number of months. The Bureau would also like to receive applications for appointment as assistant engineers for the same purpose at $150 to $250 per month, the pay depending upon individual experience in the mining of the minerals covered by the Act.

SECRETARY WILSON, of the Department of Labor, told the conference of Governors and Mayors that it was folly to attempt the reduction of wages at this time, because it was possible to lower the cost of living, and of materials generally, without interfering with the existing rates of pay. To this doctrine we shall not demur, for it is not the cost, but the inefficiency of labor, that is the chief handicap of industry in these days. The Government shipyards and the other shipyards and factories engaged in doing Government work have presented a spectacle of inefficiency that is appalling. Profiteering and inefficiency together have sent the price of the necessaries of life skyward and upset both national and domestic economies. Intelligent employers do not object to high wages if it yields efficient labor, but they do protest against being victimized by a service that is both costly and inefficient. We do not overlook the rank imposture of the patriotism of sundry manufacturers who used the War as an excuse for business of a predatory character, raising prices simply because the public was helpless, but we doubt whether anything so glaringly fictitious was presented during the War as the 'patriotism' of the young workers who demanded double wages under cover of 'holding the trenches' at home and of 'backing the soldiers' at the front. They remind us of the man "who fought with Sousa"—and his band at a naval station on Lake Erie. The discontent of Labor is due in part to the reaction from the exorbitant pay and lax supervision of an abnormal period—to a disinclination to return to normal conditions, which include specifically a degree of efficiency that will promote economy. We question whether the copper miners, for example, have profited more from the War, or profited less honorably, than the companies and shareholders by whom they were employed, but we do believe that the mad rush to put men to work at fancy wages on highly profitable ship, munition, and armament contracts has demoralized a large part of the labor population and established a standard of inefficiency that is not to be endured.

The League of Nations

We envy Mr. Taft. It is an eminently gracious act at this time to be able sincerely to support the President in his advocacy of democratic ideals at Paris, and it is particularly fortunate for a Republican ex-President to be able to play this graceful rôle before the world. Certainly he cuts a more dignified figure than sundry senators at Washington whose opposition unfortunately for them appears to be colored by political prejudice. Mr. Taft's tour of the country in company with the president of Harvard university, the ex-ambassador to Turkey, and other distinguished citizens equally earnest in their support of Mr. Wilson's proposals for preventing war, is bound to make a profound impression on public opinion in Europe. It strengthens the President's hands enormously. We would like to be equally enthusiastic in favor of this league "to enforce peace," for any sane man must wish with all his heart and soul to ensure civilization against suicide, but it seems to us that in the hurry to interpret ideals in terms of international compacts there is a failure to take account of the concrete duties ensuing from an acceptance of the abstractions now being ventilated at Versailles. After a journey from San Francisco to New York, in the course of which we read the various newspapers available along the line of the railroad, we detect a lamentable failure on the part of the public to recognize the responsibilities involved in the President's propaganda. He has forced the idea of a League of Nations into the foreground of international politics and he has succeeded in obtaining a general acceptance of that idea, as expressed in the preliminary constitution drafted immediately before his return from Paris. Apparently Mr. Wilson has overcome the opposition of the French delegates, more particularly M. Clemenceau; he has been enabled to impose his wishes upon the Conference by reason of the prestige of the United States, the support of the English delegates, and the enthusiasm that he has evoked among the liberals in every one of the Allied countries. The United States, by its belated but decisive participation in the struggle of the nations and by the obviously disinterested character of its international policy, has occupied a dominating position at Versailles. To the exhausted belligerents in Europe the President of the United States came as the prophet of a new dispensation, to the imperialistic traditions of the old world he brought the promise of a reconstruction based on the democratic ideals of a new world. He was received with acclamation and he was heard with deep respect. If most of the delegates from the other countries listened to him so approvingly, despite the growing anxiety of the French premier and his associates, it was because they believed that Mr. Wilson had a mandate from the United States and that anything he undertook to do would be performed in due course by the great nation whom he represented. Has he such a mandate? At the present time the President is opposed by a large proportion of the Republican party, but he has the enthusiastic backing of all the idealists and pacifists, without respect to party, that is, of the big mass of the people of this country, horrified by the War, eager to prevent a repetition of it, and confident that a means can be evolved to do so. But do the supporters of the League of Nations realize the responsibilities to be incurred, to be accepted and loyally fulfilled, by the United States? We think not; and therein lies a grave danger not only to this nation but to the world at large. The acceptance by us of the League proposal would involve the maintenance of an expeditionary force and of the multitudinous equipment, including transport, required to transfer it for prompt service in Europe, or elsewhere, whenever the safety of the League was jeopardized. Such an expeditionary force would not be one of less than 100,000 men and might be possibly 250,000. Another responsibility implicit in our joining the League would be the acceptance of a mandatory to administer sundry troublous regions, for example, Armenia and Georgia, and possibly to provide a government for Constantinople, the warder of three continents and the gateway of the Near East. America's share in the rehabilitation of Europe will involve burdens not lightly to be considered, much less ignored. Besides soldiers and governments, we shall have to provide large sums of money as our contribution to the cost of so policing and protecting an unquiet world that peace may be preserved. Moreover, if the United States becomes a signatory to the international covenant to preserve peace she may have to forego sundry rights now freely exercised, such as the control of immigration, the expulsion of undesirable aliens, the fortification of the Panama canal, and the regulation of our foreign trade by tariff or embargo. It may not involve the abrogation of the Monroe doctrine as applied to the Americas, but it will involve us in the "entangling alliances" so feared and disliked by our forefathers. Mr. Taft says that "the League of Nations was invented for the purpose of extending the Monroe doctrine to all the nations of the world, and it is proposed that the league stand behind it to see its enforcement." Mr. Taft is a jurist, so his dicta concerning the Monroe doctrine and the constitution are authoritative. He says that the proposed covenant does not conflict with the constitution of the United States, yet we can imagine the conferees at Paris asking each other "what is a constitution between friends" and proceeding to take liberties even with so sacrosanct a body of fundamental principles if thereby they could further the peace of the world. With such a great gain there must be some minor losses. Any international partnership for good work involves some sacrifice of national freedom. Even the relinquishment of some part of the sovereignty of the United States is not terrifying, for every decision of international law involves some surrender of national rights; they are conceded just as the individual citizen foregoes some of his private rights for the sake of the community as a whole. None of these things need intimidate us at this time when so earnest an effort is being made to stabilize international relations; it is worth while to surrender a good deal for the sake of ensuring peace and of saving the world from another hideous calamity such as we have but lately witnessed; but we must know what we are going to do, we must be told just what responsibilities are to be assumed by the United States. The President in his last speech, made the night before he sailed from New York, referred three times to the sacrifices this country will be called upon to make. He said that "we are ready to make the supreme sacrifice for an idea; the supreme sacrifice of throwing in our fortunes with the fortunes of men everywhere." He prayed God that we would not falter, that we might be given "the privilege of knowing that we did it without counting the cost, and because we were true Americans, lovers of liberty and of doing right." We share that pious hope and look forward to the consummation of it, but we venture to suggest, at this critical period of international reorganization, that the people of the United States ought to be told—in the first instance by the President, and secondly by such leaders of public opinion as Mr. Taft—just what the "sacrifice" or the "cost" entails. Before this country is committed to so basic a departure from established policy and before the President affixes his signature, as our representative, to a solemn covenant—not a 'scrap of paper'—binding the United States to many serious obligations, it is imperative that full information be given to the people. If in the enthusiasm of the moment we permit the President to bind this country to membership in the League of Nations and if afterward we shirk the fulfillment of the duties imposed upon us, we shall be stultified, if not indeed dishonored. We intend nothing of the kind, therefore we want to know just what it is to which we are to be committed. For ourselves, we do not fear that these obligations will be too heavy a price to pay for an enduring peace; we pray for the success of the Paris conference; we are in no wise intimidated by the speeches of Senators Reed and Sherman; but we do ask for the information to which every thoughtful citizen is entitled. There is no quick way of ascertaining the will of the nation in such a matter as this; the President comes more near to interpreting the national sentiment, we believe, than most of his noisy opponents at Washington, but he has received no mandate for his actions at Paris, except his election in 1916, the force of which was weakened in the congressional election of last November. All the more therefore he should, we submit, take pains to inform the public concerning the conditions governing the League of Nations, so that our people may have a proper understanding of the tasks we are accepting. Tell us, Mr. President, what we are to do in this matter, and we will face the music manfully.

International Control of Minerals

The underlying motive in the paper by Mr. C. K. Leith, which we reproduce elsewhere in this issue, is to utilize a principle which had developed suddenly in working form under the pressure of war, for the assembling and distribution of minerals more economically than in times past. He asks "whether the centralized international control required by the War shall be retained or extended as a means of furthering the aims of a league of nations." Viewing one aspect of the case, an affirmative answer might be given. If the nations were to be organized into a universal State, if they were to surrender the administration of their economic activities to a central governing body, and if, in place of private initiative and the spontaneous operation of the law of supply and demand, there were to be substituted a controlling board to regulate the production of raw materials and manufactured commodities, giving, in effect, a sort of cartel system, expanded for application to a world-wide highly socialized government, the international control of minerals would follow as a logical necessity. Since the article by Dr. Leith was written the draft of a constitution for the proposed league of nations has been placed before the world, and it is seen to signify a closer association of independent nations, each retaining the right to manage its own affairs in matters of trade and internal development. Therefore the world comes back to the old principle of self-sufficiency for each political entity, so far as that may be attainable, and questions of pure economy must be modified by considerations, on the part of each commonwealth, of the problem of self-preservation. The more elaborate artificial characteristics of the ideal of international control of essential commodities are therefore eliminated, but there were some advantages in the plan suggested by Dr. Leith that may still be retained. Since it is fashionable at the present time to be idealistic, one is in no danger of being suspected of mental errancy by stopping to consider politico-economic theories that are apart from the usual program of hum-drum business. Five years ago a man would have been set down as a dreamer to have recommended international control and 'allocation' of basic supplies; today it puts him into the class of neo-progressives to advocate such reforms. The symbol of this new party has not yet been adopted, but there is no evidence to suggest that the Bull Moose will evolve into a type suitable for the purpose. Seriously, the conception possesses features of merit. Man has always been wasteful, even when not prodigal. The time may be at hand when he should display a wiser sense of responsibility in his use of the products of the earth. Nevertheless, we must beware the error of Babel and not aspire to usurp and surpass the prerogatives of providence, whose scheme of economy seems also to involve waste for the sake of achieving particular ends. While mindful of the conservation of forces, which depends on transmutation of energy, we are also not forgetful of the millions of eggs that go to the making of a single adult codfish. Leaving playful philosophy aside, we urge that problems of conservation be weighed seriously and that suggestions for developing workable plans be not neglected. Among the ideas recently advanced is one that deserves attention, because it seems to offer a practical means for promoting the distribution of raw materials, without introducing the harsh methods of exclusion by rigid protection. This, so far as we know, originated as a proposal by Mr. Franklin K. Lane, the Secretary of the Interior, for the encouragement of potash production in the United States. It would necessitate appropriate legislation requiring that some definite proportion of the domestic output, at a fixed price, be used in conjunction with imported supplies of the same material. It was suggested that the price of the home product be established at $2.50 per unit of K_2O, and that an amount of the American salt corresponding to the ratio that the American output may bear to the total consumption should be employed by all prime users. This method of fomenting a domestic enterprise holds possibilities for wider application. It would conserve the benefit of economic development of the industries that depend upon a particular raw material, without subjecting the country to the burden of abnormally high prices to protect them where their future magnitude and value might be open to doubt. Conservation is a complex problem. It involves not merely getting what is wanted from any part of the world at the lowest possible cost, nor the limitation of output in view of the needs of coming generations, nor the distribution of materials on an ideal basis of economy; it demands consideration also of the need of each nation to become as nearly self-supporting as possible. That is one guarantee of contentment, leading to the elimination of a form of commercial cupidity that is the frequent disturber of international peace.

DISCUSSION

Buy It Now!

The Editor:

Sir—There is a lot of more or less loose talk going on about reconstruction, rehabilitation, post-war re-adjustment, or whatever you have a mind to call it. In other words, business is most certainly not good, particularly in contrast with the flush industrial conditions and high prices for material and labor that obtained during the period of the War. Nevertheless, business is worse than it should be, and we all of us are responsible for this state of affairs. When will things start up again? The answer is, when you do your part to start them up, and not before. Everybody, from the office boy to the trust magnate, from the mucker to the mine manager, is sitting on his haunches gazing speculatively at the market quotations, his hand on his watch, expecting a sort of low-water-small to enable him to buy what he wants for less than it is worth. That may be business in one sense of the word, but it certainly is not in another. It spells idleness, rather than business. You who want a return to 'business as usual', trot out and buy something, and buy it right away. If you have a strike on your hands, or are operating on part-time with a reduced working crew, utilize this opportunity to overhaul your plant equipment, make those changes that have been in your mind for eighteen months. Install that new, more efficient, air-compressor, ball-mill, power-plant, or whatever it may be that will lower your costs when you resume operations. The quicker you get it in, the quicker it will make returns on the investment. If you wait for the rush that will come as people gradually return to their sense of the realities of things, you won't get the delivery you want, and you will have wasted the golden opportunity. The old familiar saying about saving at the spigot and wasting at the bunghole is apt. You might, perhaps, save 5 or even 10% in the purchase price by waiting six months or a year, and even that is questionable. You might also lose the use of this same piece of apparatus, or those supplies just when you want them most, which would make your theoretical saving look like thirty cents compared to the much larger issue of impairment in efficiency, and much greater loss on this account. Then there is the greatest issue of all. We, as a people, are dependent absolutely upon one another. Where there is a tendency so general as now exists to buy nothing, start nothing, and do nothing: where everybody expresses the hope that 'business will pick up soon', and does nothing on his own account to make it pick up, you have begun to raise a crop of hard-time tares for which you yourself are principally responsible. Cut it out! Place your orders! You will inspire confidence in the fellow who gets them, and he, in turn, will pass on the glad tidings that 'business as usual' has returned, and the first thing you know you will have a demand for your overstock of metals.

C. T. Hutchinson.

San Francisco, March 4.

Rossiter W. Raymond

The Editor:

Sir—Without the suggestion of yourself and the President of the Institute I would not have thought of intruding in any way between Dr. Rossiter W. Raymond and his work and a mining audience to whom he and it were so familiar and appreciated. Raymond was no office knight, but a chief among men on any occasion, a great artist in his work, performing all duties to the best of his ability.

From 1885 to 1895 I was filled with gratitude for his labors on the Transactions of the Institute, and the 'Engineering and Mining Journal', regarding these publications with those of the U. S. Geological Survey as my alma mater, and he and his brilliant confreres as my generous and enthusiastic professors, and I always felt deeply for myself and other young men how much we owed to himself and associates. Their example probably molded the American mining engineer, by imitation, into the splendid aggregates and individuals who have been called on for such important duties during the War.

In taking charge for the War Eagle and Centre Star mining companies, at Rossland, B. C., I inherited an apex suit, Iron Mask v. Centre Star. Both our mines and those about them were taken under the first lode location law of British Columbia, which followed the American law, with extra-lateral rights. The B. C. law was quickly replaced by the present one of 1500 ft. square locations and vertical boundaries. The idea of digging under another person's property was so alien to the English law, that the only precedent was that of digging in Yorkshire for a hundred feet or so to find a drain. But the Court expressed itself as wishing in decisions and rulings to follow U. S. precedents.

As I disagreed with the depiction of the geology in the preliminary Iron Mask v. Centre Star suits and injunction proceedings, it was necessary to engage new council and witnesses. There was much at stake, for the purchase price of the War Eagle and Centre Star mines by the two companies was $2,700,000, and $500,000 had been spent for equipment.

The legal personnel was organized as follows: Edward P. Davis and Aleck C. Galt, attorneys, with Thomas P. Galt as further counsel and directly representing the Eastern owners. Rossiter W. Raymond, Clarence King, and Waldemar Lindgren, were the leading witnesses, assisted by members of our staff, Walter F. Ferrier on petrography and geology, Theodore Simons and Roy H. Clarke for the maps and models, Arthur A. Cole for assays and analysis, and Henry Kehoe, Joseph J. Taylor, and Guy H. Kirkpatrick, as general assistants, all members of the Institute.

The Iron Mask company was represented by Bodwell and Duff, lawyers, and Louis Janin and W. S. Keyes as leading witnesses. In presenting their view of the geology they had obtained a written opinion from Curtis H. Lindley, and I, with my own view of it, had one from John Forbis. The case was heard before Judge Walkem, at Rossland, in 1899.

On arrival, Raymond took charge of the case, but in doing so he did not detract from the initiative of King and Lindgren. As I went underground with all three, I know that from end to end of the workings exposed, in the ground in conflict, there was no seam or slight differentiation of the rock with which they were not familiar. Raymond was delicate, and husbanded his strength better than the others, by intenser application, satisfying his memory and note-book with fewer trips.

One of our main workings in conflict was a 25° inclined shaft where a continuous streak of pyrrhotite ore, averaging ten inches thick, was claimed. Rossland veins were not remarkable for crustification, and almost any vein might have been excused a lapse of a few inches of continuity in such a sulphide stretch. I had installed comfortable stairs and landings, and electric lights, and water-pipe to wash the whole exposure clean, greatly to the delight of Janin, whose avoidupois matched his fine disposition. I went down the incline with Raymond on his crucial examination. He put the point of his pick on every weak spot, "How about here?" but the continuity always held.

After conclusion of the Raymond, King, and Lindgren testimony the Iron Mask attorneys pleaded the geological version was so different from that in the preliminary suits that they needed a long time to prepare a rebuttal and asked for a year's adjournment, which was granted. The suit did not get into court again.

Next year, not being willing that our case should depend in the mind of the Court on memories twelve months old, I engaged S. F. Emmons, Walter H. Wiley, and Samuel S. Fowler, but these gentlemen did not appear in court, because the Iron Mask consented to our writing the verdict, each side paying its own cost. Our direct cost was $65,000, indirect $60,000 more; the Iron Mask direct cost was $15,000. It is not known whether Janin and Keyes differed from Raymond, King, and Lindgren on the geology; as I have stated, these were the only witnesses heard. Their printed testimony fills a quarto volume, and, coming without revision from the stenographer may be said not to need correction.

It was the first experience of our attorney, Mr. Davis, in mining suits and parlance. After he had patiently mastered volumes of geology and thoroughly digested the maps and models he was taken in state by all hands underground to see what it actually looked like. But presto, all the careful training was gone at once, the flat fault, the co-ordinate fissures, the junction of the veins, etc., were irretrievably mixed in that noisy, dirty darksome hole, so he was quickly hurried to surface and put to bed with Professor Simons' large model on a table by his side. Before the trial began he had entirely recovered. This incident made me wonder about the capability of judges to decide the facts, by visits underground, where differences of opinion exist between highly trained engineers. I am quite confident, however, that, in extralateral litigation, if the Nominating Committee of the American Institute of Mining Engineers were requested by the Court to name 25 engineers and from this number three or five were chosen by lottery, the litigants paying fees and expenses in common, the Court would receive such an intelligent and correct version of the facts that a just verdict, according to law, could be rendered.

Sometimes the 'enemy' would dine with us. Janin would tell us plaintively about his California ranch, where his wife was trying to raise chickens, and he a mortgage, or he would complain of our hanging wall with its hinge that allowed a vein to open like a crocodile's maw. Keyes would portray the terrible fate in store for us when they took the stand. Raymond, who had but recently been victorious with Keyes as an opponent, said he could only reply like the Yankee to the irate and threatening Britisher's talk of invasion, "What, again?"

Raymond and King had the common trait of drawing out the best in men, the former technically, and it helped to obtain the valuable contributions with which he filled the Transactions. King was a warm ray of sunshine and the most limpid thoughts of his auditor would creep out to bask in his sympathy. To the amusement of his colleagues, his most enthusiastic reception in Rossland came from a portly colored matron, who, shaking his hand with both of hers, said, "Why, Mr. King, where did you come from? I'se sure glad to see you." Probably either a dinner or a sealskin coat had been shared with herself and babies on a rough trip.

I am sure all present at the Raymond 70th birthday dinner have been looking forward to the 80th one and are sad it is not to be. He sent me greeting from the 1905 Rossland meeting regretting by inability to attend where "We had fought a good fight and a clean fight."

JOHN B. HASTINGS.

Los Angeles, February 4.

Misfires

The Editor:

Sir—There is so much loss of efficiency from misfired caps, and so much danger to life and limb from accidents caused by re-shooting, that a glance at the fundamental causes of misfired blasting caps will not be out of place.

An examination of any misfired blasting cap always shows the surface of the cap marked with burnt carbon; the spit of the fuse has come through and the fire had not been sufficient to accomplish ignition. Potassium nitrate and other chemical ingredients in the fulminate of the cap-charge are exceedingly sensitive to moisture, and since nature is constantly striving for a balance between elements in opposition, the present method of putting fuse and caps together, is perhaps unwittingly artificial in the light of a fundamental principle. When a railroad train enters a tunnel, the moisture is instantly deposited on the window glass; so also when blowing your breath on a glass surface, or when a glass of ice-cold water is brought into a hot room.

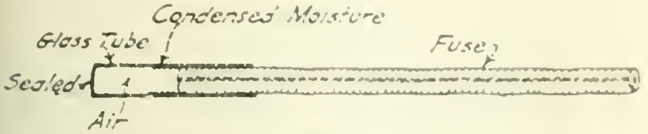


FIG. 1

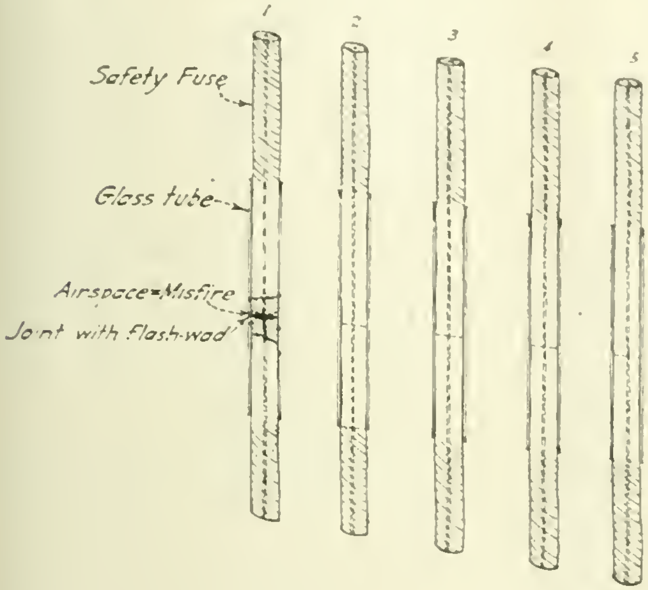

FIG. 2

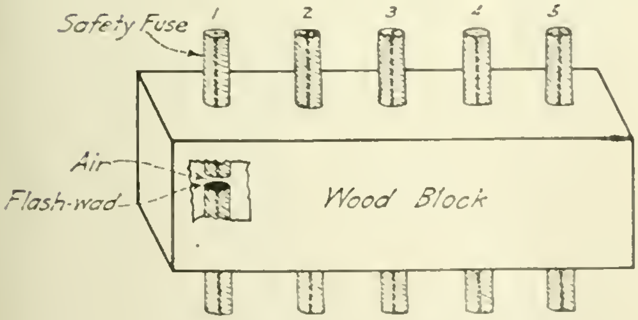

FIG. 3

Any plugged receptacle will contain compressed air; a perfect vacuum is secured only by an exact mechanical process; so it is clear that air is caught in the blasting-cap when the fuse is put into it. Moisture is condensed always from the spit of the fuse inserted in a glass tube, and it will be noticed before the fire spits out at the end in the glass that fume precedes the fire. It is a well known principle that 'sparks fly upward', which will answer at times for an insufficiency of heat coming through the fuse causing misfires. When the fuse is spitted, the fire finds a path of least resistance, leaving too little powder at the point of contact with the charge in the cap, and thus it cannot overcome the presence of the air in the space between the charge and the end of the inserted fuse; the result is inevitable. Many tests made with different brands of fuse show extreme differences in the end spit of the fuse, and in the amount of fire delivered when the fuse spits. The per cent of misfires from the natural spit of the fuse is shown in Fig. 2 where the fuse is held lightly on little squares of magnesium paper, (Eastmen's No. 1 flash sheets) and fired with a shield to protect the hand. In this case double tape waterproof fuse gave one misfire in five shots.

The proportion of misfires in Fig. 3 is about the same as in actual blasting. The dryness or humidity of the atmosphere has much to do with the results, but this can be corrected and perfect shooting of the blasting caps obtained by the use of a supplemental pinch of meal-powder in the cap, which is then well crimped and sealed with asphaltum paint.

A. J. AVERILL.

Medford, Oregon, January 20.

Stimulation of Gold Mining

The Editor:

Sir—In viewing the situation it must be borne in mind that gold is the standard of value and cannot be changed. It has been established at the fixed valuation of \$20.67 per ounce. Should a bonus be paid upon gold production, it simply increases its value. To increase the value of a standard, relatively increases all that is based upon it, and the standard is no longer a standard. The removal of the excess-profit tax will stimulate mining investment by creating in the public mind the idea that the Government recognizes the desirability and necessity of aiding gold mining. Capital will be easy to obtain to float the average gold enterprise, gold stocks will be in demand, and speculation active. It will aid the promoter and increase mining operations; but it is a question whether this is the way to go about it. Will it not injure the gold-mining industry in the long run? It cannot increase actual production to any great extent, there being no profit in the average gold-mining enterprises today, hence an exemption from taxation on excess profit means nothing.

A better plan would be to permit the excess profit taxes to go into actual underground development, improvement of equipment, and processes of mining, as well as treatment, thus putting more ore-reserves in sight; then, after the excess-profit taxes are removed, the gold miner will reap his reward. Meanwhile gold reserves will be established for future use. The average mine is being worked in a hand to mouth manner, doing only the development work that is forced upon the operators, with little or no exploration work, which is so essential to its life. It must be remembered that mining is a depleting process;

every pound of ore extracted is gone, and can never be produced again. Therefore there can only be two real assets to a mining property, the ore in sight and the money in the treasury. Many instances can be cited in the history of mining, of a mine being on its last legs, when some lucky extension or forced prospecting work disclosed new orebodies and other unknown enrichments, giving it years of profitable life. Systematic exploration work would have shown it long before its actual discovery.

In order to effectually aid the present operator to increase the production at a reasonable profit, it must be approached along an entirely different avenue. It must be broad enough to cover all the conditions, and must effectively reach the production. This must begin at the source, primarily reducing the costs. To do this it is necessary to view the situation as it is, in other words to make a plan, as the efficient architect prepares a careful plan of the structure to be changed, in order to study it, and make the alterations to meet the required conditions, so as to bring out as nearly as possible the desired results with the least disturbance. In order to study the matter intelligently a tabulated plan of the chief items of expense, in their order of size is hereby presented.

Mining

Vein

1. Labor. 2. Munitions (powder, fuse, and caps). 3. Fuel and power. 4. Timber and lumber. 5. Steel (tool-steel and castings).

Milling

Concentrators and Stamp-Mills

1. Fuel and power. 2. Steel and castings. 3. Lumber. 4. Labor.

Cyanide Mills

1. Fuel and power. 2. Chemicals. 3. Steel and castings. 4. Lumber. 5. Labor.

Placer Mining

Hydraulic

1. Lumber. 2. Steel and castings. 3. Labor.

Dredging

1. Fuel and power. 2. Steel and castings. 3. Labor. 4. Lumber.

Smelting

1. Fuel and power. 2. Fluxes. 3. Labor. 4. Lumber.

Sampling Works

1. Fuel and power. 2. Castings and steel. 3. Chemicals (assaying). 4. Labor. 5. Lumber.

The other items of expense cut but little figure and must be left to the economic efficiency of the individual management. A glance at the foregoing plan will at once reveal the fact that labor is the least item of expense in practically all except vein or quartz-mining. By a reduction of all the other items, the item of labor would not have to be disturbed. In vein or quartz-mining, by reducing the cost of powder, more could be used and thereby effect a saving of labor; in other words, use more powder and less labor. The reduction of these items will effectually aid all branches of the industry, individually and collectively, without a disturbance of the standard, taxation, or labor. This reduction could best be brought about by Government supply, resources, and regulation.

To stimulate and increase new production, we must consider:

1. Old sources: Government aid in re-opening well-known old properties and bringing into activity dormant and restricted sources.

2. New sources: stimulate systematic prospecting under supervision and direction, as prospecting is an art requiring trained observation and skill; make geological maps, and assay maps in connection with them; reward for original discovery of new sections; Government aid to open them up; the free use of the working factors and advantages of the Bureau of Mines and the Geological Survey. The needs of the prospector are quick and reliable assaying, especially gold and silver determinations, therefore there should be free Government-assaying of gold and silver. There should be less discouragement and persecution of prospectors and miners by agents of the Land Office and Forest Service; and the opening to prospecting and development of all mineral lands within Indian reservations including those established by executive orders, upon a proper royalty basis.

3. Guarantee: Government control and establishment of sampling-works; Government control-assaying to determine the true and full valuation of all precious metals, ores, and bullion.

4. Control: Government control of the distribution of gold through its mints and by controlling or supervising all refineries.

5. Revival: encourage investors by the advantage of Government aid the use of the Bureau of Mines and Geological Survey; Government aid and encouragement for developing prospects; Government aid in new districts for transportation, milling, and smelting facilities.

In presenting this it is hoped that there will be further discussion and criticism. It requires someone to create, someone to execute, and a multiplicity of brains to attain perfection. Under improved conditions the gold production in the United States would be doubled in a comparatively short period of time, and a supply created for our future needs.

Charles A. Lawrence Gehrmann.

Oatman, Arizona, February 14.

The commercial feasibility of the electric smelting of iron ores in British Columbia is the subject of a report (Bulletin No. 2 of the Department of Mines, Victoria, B. C.) completed by Alfred Stansfield, professor of metallurgy in McGill University, Montreal. He concludes that the problem is perfectly feasible from a metallurgical point of view; that the Province has a sufficient supply of ores of a quality well suited to the process and capable of being converted into high-grade iron or steel; and that there also are available all fluxes wherewith to carry out the process completely. But two difficulties are made clear, namely, the present cost of power and the limited market for the products.

Californian Petroleum and the European War

By J. H. G. WOLF

In an article bearing the same title that I contributed to 'Western Engineering', in October 1915, I traced the course, to that period, of the influence of the War upon the petroleum business of California; the notes here presented will carry the review to the close of the War. The outstanding facts appear to be:

1. On the day that the War started the crude-oil production of California, as well as the consumption in the Pacific region supplied by California, reached the imposing figure of 300,000 barrels per day, a greater quantity than had ever before been steadily produced by any State in the Union, or by any country in the world; the other oilfields of the United States were then producing 500,000 bbl. per day. During the years 1910 to 1912, the crude-oil stocks in California were increased by 28,000,000 bbl., indicating that markets had not yet been found for the surplus production, but the excessive accumulation of stocks ceased with the year 1912, and from January 1913 to June 1914 the surplus was only 4,000,000 bbl., which meant that consumption had about overtaken the rampant production. On January 1 of each succeeding year, from 1910 to June 1914, the consuming market had been absorbing 33,000 bbl. of oil per day more than on the corresponding day of the previous year, while the production, after January 1, 1913, increased at no greater rate than the consumption. The local industry, if not entirely and fundamentally sound, because of the low prices that the product was bringing, was, as a whole, in a flourishing condition on the day when the War started. The great marketing agencies were expanding their facilities in keeping with the demands of trade, and an ultimate output of 400,000 bbl. per day seemed not unreasonable to expect. The great Midway field, covering about 36,000 acres, or 55 square miles of proved oil-land at the southern end of the San Joaquin valley, was still in its first flush of high production under the influence of original high gas-pressures. Flowing wells, gushers of large capacity, ruled in nearly all sections of the newer territory.

2. Then came the holocaust. In common with its effect on all branches of industry the outbreak of the War caused an immediate break in the local oil business. The reason for this is not difficult to understand, for crude petroleum is the sub-structure on which many enterprises are founded. In the multitudinous applications of crude and refined products it lies behind the economic life of the whole Pacific region. That is truer here than elsewhere in the United States because of the lack of other fuels. When the wheels of orderly progress were suddenly arrested, the effect upon this basic staple was instantaneous. There was a break of 70,000 bbl. per day in the consuming power between the high point in June 1914 and the low point in February 1915; and because production could not be curtailed fast enough there ensued a further accumulation of 8,000,000 bbl. of stocks on hand, while the shut-in production, that is, developed but not utilized production, mounted to 28,000 bbl. per day, as reported by the Independent Producers' Agency. The Pacific Coast, being so far removed from the industrial centre of the Nation, did not at any time share conspicuously in the activities engendered essentially by the War, hence business did not receive that temporary artificial stimulus, and recovery in the spring of 1915 came solely as a reaction. Plainly the War proved a heavy blow to the industry, from which in fact it has not recovered, particularly as regards the vital question of output, and such improvement in prices as has occurred is due, if the situation is correctly interpreted, to the lessened available supply. When the business paralysis from the shock of war had passed and the normal demand for fuel-oil had returned, it was seen that the once abundant supply was curtailed, that production could not be brought back for reasons to be stated, whereupon prices began to mount immediately. The lowest prices prevailed in 1912, being 30c. per bbl. for low-gravity oil. There was improvement in the spring of 1913, when it was found that the current consumption had been brought about even with the production.

3. The features of the third phase of the story of the War, as written in this industry, can best be seen or followed on the accompanying graph. The crude stocks reached their apex at 60,000,000 bbl. in the mid-summer of 1915, while the price of low-gravity oil at the well again scraped bottom, or dropped to the ridiculous figure of 33c. per bbl., which meant that fuel consumers on San Francisco bay, 300 miles from the point of origin, got their supply at a price of one-third its economic value. If the atmosphere was hazy at this period, the clouds at most were thin, for, with the return of a semblance of normal conditions, the pre-war rate of expansion in consumption, namely, 33,000 bbl. per day per annum, was again quick to assert itself. This condition prevailed until about January 1917, when new elements appeared halting further progress. Throughout the period of readjustment, while consumption was working back to the previous 300,000 bbl. per day, production lagged, and the best the oilfields could do, when a renewed demand was made, left a deficit of 1,000,000 bbl. per month, so that on 28 months, or by January 1, 1918, stocks dropped to 32,000,000 bbl., which was the amount that had been in storage on January 1, 1919. On the other hand, prices began to move up the moment the draft on the stocks became noticeable, or as soon as it was seen that production no longer responded to the current demand, and the

upward movement in price continued as long as this draft persisted. It stopped only when the drawing ceased, resting at $1.23 per bbl. Major developments do not as a rule flow from single causes, but are the result of many contributing currents and counter-currents, just as the War itself resulted from complex causes. It is therefore difficult to say just what factors govern prices in the local business, but it is obvious that the current available supply, rather than the crude stocks on hand, comes near to being the major consideration; in other words, the first principle in the law of supply and demand governs here as elsewhere.

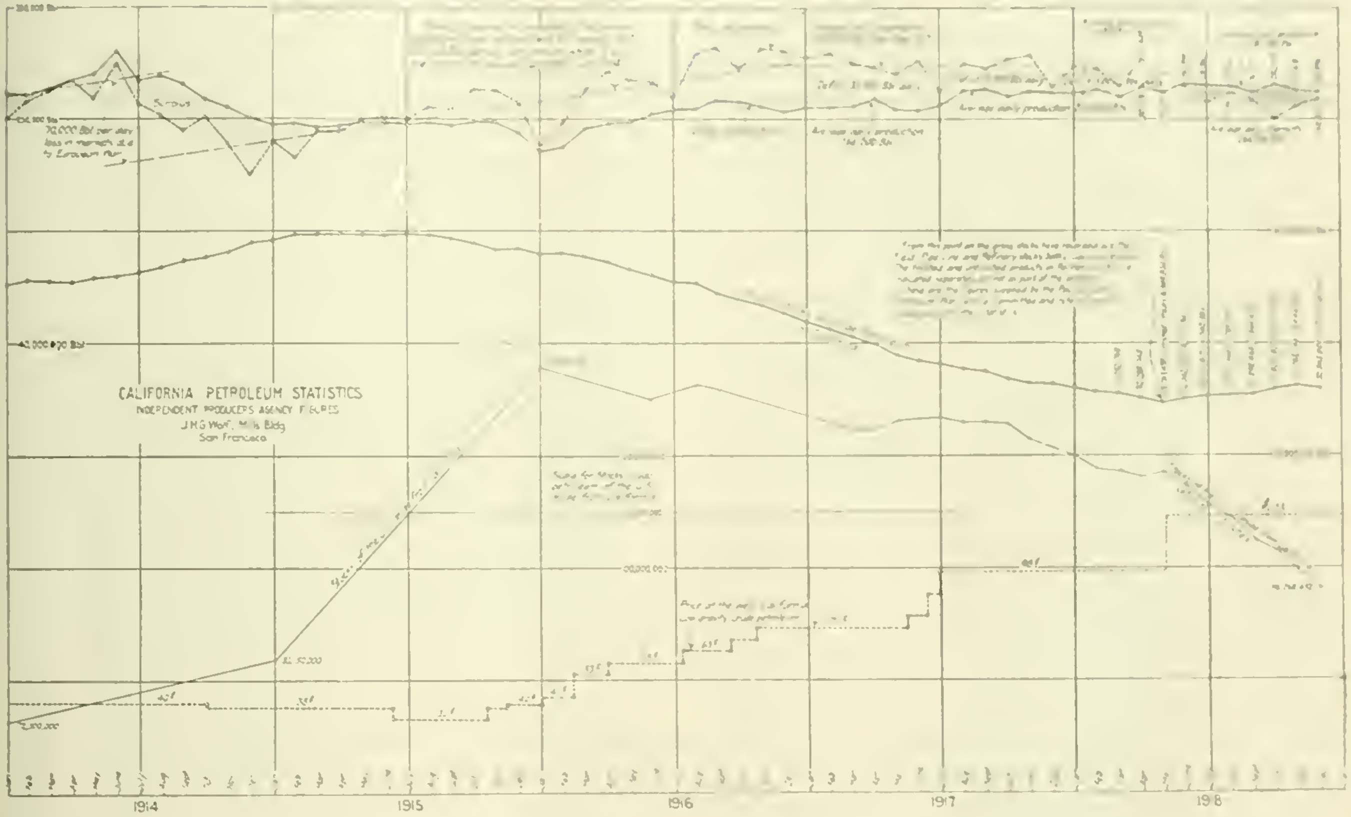
4. Granting that this diagnosis is correct, and that it is the failure of production to respond which has caused the present unsatisfactory situation, it is desirable to examine briefly the reasons for this condition.

The oilfields of California had, in 1914, developed by easy strides a larger output than was ever recorded in any oil region anywhere. The wells of the State were yielding 50 bbl. per day per well from 6150 wells, as compared with 3.5 bbl. from 200,000 wells for the oilfields of the United States outside of California. The output during June 1912 and 1913, had also been 50 bbl. per well per day. In 1915, when the business equilibrium was re-established, and the demand for crude oil struck its accustomed pace, the valves of throttled wells in the oilfields were again opened, but it was found that the wells did not respond. The 'sleeping potion' had been administered too effectually. Frantic efforts by operators to restore former conditions were unavailing, the virgin gas-pressure had failed, and the flowing wells, with few exceptions, which had at one period painted the desert hills with tawny black (or the 'brown gold' of the oilfield poet) had now become ordinary pumping wells. In these six months of repression the production dropped from 50 to 40 bbl. per well per day, and the reduction since has gone down to 33 bbl. This drop of 20% in the first six months was in spite of the fact that during this period wells of large capacity were completed in one of the Southern fields (Whittier-Fullerton). The 28,000 bbl. of shut-in production, when called upon, proved to be largely mythical; the oil had been held back altogether too successfully! The daily production could not be brought back to as much as 250,000 bbl. per day until the middle of 1916, and an average of 266,000 bbl. per day was not exceeded until July 1917, when the influence of the flush production of a new field in southern California, the Montebello, began to assert itself. New wells to the extent of 40% above the number producing in 1914 have failed to prevent a drop in the yield per well to 33 bbl., which is disquieting, in whatever light it may be viewed.

Why does the failure of production to respond to the demand, despite the fact that California has 85,000 acres of proved oil-lands of which not over 20% are intensively drilled, trace back so directly to the failure of the gas-pressure? What has gas-pressure to do with oil production? It has long been known that there existed a close relationship between output and pressure; that the first wells drilled in a new field usually 'came-in' as flowing wells, but that the subsequent wells in the immediate territory proved only nominal producers. Recent research on this subject brings out the important fact that this close relationship, heretofore recognized but not accurately defined, is susceptible of analysis and definition, and can be expressed satisfactorily in empirical laws and general principles. This research shows that there can be no turning back when once the exploitation of an oil-deposit is begun upon an extended scale, provided, of course, that the maximum output, or the maximum possible recovery of oil, is sought. With a resource so important, and so fixed in volume as crude petroleum, every barrel originally available must be won if broadest interests are to be served best. The reason why the gas-pressure holds the power it does over oil production is found in the principles governing the occurrence and existence of the oil underground. It has only required this tremendous experience, revealed here in this instance at the cost of untold millions of barrels in the ground now rendered unrecoverable, to verify the important technical fact involved. In the briefest possible terms the impulse behind oil production is the natural gas with which it is so intimately associated. Crude petroleum is a mixture of many complex hydrocarbon substances existing in several physical forms, that is, as gases, liquids, and solids, the first and third forms being incorporated or held in suspension in the second. Under certain conditions of pressures and temperatures in the earth, some of the oil that is in the gaseous state becomes liquid, and, again, certain portions existing as liquid may, under changed pressures and temperatures, become gas. In other words, the forms in which certain portions of the oil exist undergo a change with variations in the physical conditions surrounding the deposit. The gaseous part of crude oil constitutes one portion of the natural gas which accompanies the oil. In the ultimate analysis the crude oils from all parts of the world do not vary sensibly from the following proportions: carbon, 84 to 86%; hydrogen, 12 to 16%; together with small percentages of oxygen, nitrogen, and sulphur. However, in the chemical association of these organic elements there is the widest range of combination in every oil, which produces so many different hydrocarbon substances that the world's chemists seem yet to be uncertain as to their number, or as to the number that can be isolated from crude oil. Eighteen different series of component compounds have been isolated, and each of these in turn is composed of many members. In composition, the series conform to the general formula $C_nH_{2n} \pm 2$. The hydrogen component becomes less as the series rises. The first, or paraffine series ($C_nH_{2n} + 2$) which is broadly the predominant one in all crude oils, is also the series of which natural gas is generally almost wholly constituted. Methane, which always exists as a gas under ordinary conditions, is the first member of the paraffine series; it also constitutes from 80 to 90% of the ordinary natural gas of commerce. Here is an explanation and a reason for the intimate association of oil and gas; the former probably does not exist in the natural state without the latter. As a rule oil froths when it issues from the ground, and settles as much as 30% in volume in the receiving tanks, from the release of the low pressure gases. This is particularly true of the heavy oils. The low-gravity asphalt-base oil is a heavy viscous substance, and in its natural state is locked in the minute pore-spaces between the sand grains, and there must of necessity be some pressure like that of expanding gas to cause much of it to leave the sand-filled chambers. At best a surprisingly small proportion of the oil of this character contained in the sand is won under the most favorable conditions.

All are familiar with the manner in which oil clings to a piece of glass: it does not drain away, and can hardly be removed except by rubbing or by dissolving with distillates. How much more so must it cling in the voids among the sand-grains, which are only particles of silicates, in effect the same as glass, and where the wetted perimeter of each minute chamber is large compared with its volume? Unquestionably, a force like that of expanding gas is required to eject or push the oil from its containers. The force of gravity must be largely ineffectual, for this purpose, for reasons that are obvious. The only conception that will explain how the oil is moved at all, is that it probably exists underground in a finely divided, or possibly emulsified state, in a 'bath' of gas, if that expression be allowable. The ore of a quartz-vein of a mine is a fixed and tangible entity, and can be seen and studied at leisure; the oil in a 'vein' of oil-sand is a fugitive substance; it cannot be seen in place; it alters its form and even its composition on coming into view; and the facts as to its underground state must be studied largely through deductive evidence. There is even the widest diversity of opinion among scientists as to its origin, hence it is not strange that there should be uncertainties as to the facts regarding its physical state and its underground movement; an untraversed field of large area is yet before the investigator.

Analyzing further the conditions of occurrence, the gas being very light and less retarded by friction and capillarity, and being also under compression, travels faster toward the well-opening than does the oil, and the natural tendency is to drop its burden of finely-divided oil with the release of pressure. Oil, being a liquid, is incompressible, and the two substances exhaust themselves at different rates. Hence a well will drain the gas from a wide territory if not suitably controlled, whereas it may at the same time drain but a small part of the oil in its immediate vicinity. It is therefore evident that every cubic foot of gas must be made to do its maximum duty in the work of expelling the oil, and recognition of this fact is of cardinal importance in selecting the time as well as the position for drilling new wells.



On the foregoing premise, the arrest of development in these oilfields in 1914, undoubtedly allowed the wells then drilled to dissipate pressures over wide areas. When drilling was resumed the agency for expelling the oil was lacking in both volume and pressure, and flowing wells of large capacity, except in some instances, became conspicuous by their absence in regions where big wells had before been common. This is the simplest explanation of the reason why the oilfields could not respond when called upon, and why wells of the character of those brought-in from 1910-'14 can never be duplicated, except when drilled in uninfluenced territory.

This condition is most common in the great Midway-Sunset field which comprises 42% of the known oil-lands of California. Whereas the San Joaquin Valley fields, in which the Midway is situated, yielded 80% of the output of California in 1914, not over 62% is now coming from this area. Without the weight of production that came from the new fields of southern Caliornia, the discrepancy in supply might have grown to alarming proportions.

The aforesaid arrest of development may be attributed to be the major blow struck upon the industry by the War, which means indirectly all industries on the Pacific Coast. As a direct consequence of this loss there are facilities and equipment in the way of storage containers and pipe-lines now idle in California for handling and storing 28,000,000 bbl. of oil, which equipment was provided in the years from 1910 to 1914 by the great marketing agencies, at high cost. Whether or not these facilities will ever again be made to function is a question; the probabilities are they will not, and that the industry as a whole, and more particularly the consuming public, will have to carry not only the capital loss but the interest thereon as well.

A secondary loss attributable to the War was caused by the shunting of raw materials ordinarily used in making well-drilling equipment into munitions-channels. For long periods it was practically impossible to obtain casing, boilers, steel cable and rope, rig-irons, and the like, needed for drilling new wells. Labor costs mounted, and apostles of unrest are still abroad among the operatives in the oilfields to force yet higher costs. These and other ills which flow in the wake of such an unnatural social condition as war, have beset this industry in common with industry in general, but in the oil business, as far as California is concerned, the consequences will be felt for years to come. To speak only of one of the most conspicuous directions in which the ill-effects of this unfortunate situation will be felt: at the moment, it is the avowed purpose of the Government to put the American merchant marine back on the ocean. The Director of Operations of the fleet, now building at a cost of hundreds of millions of dollars, and at a reported cost of 50% above that of foreign-built ships, is reported to have publicly announced that the expectation of maintaining the fleet on the seas in competition with the lower-cost operating ships of other nations, is based on the expectation of having an unlimited supply of crude oil as fuel, because of the wonderful advantages of oil over all other forms of fuel. The great oilfields of Mexico are expected to afford the supply on the Atlantic, and probably will; while California, which has the only oilfields of large importance in the West, or upon the Pacific Ocean, is expected to carry the Pacific part of the burden. Because of the above, it is necessary not only, in the near future, to take care of the demands of normal trade and business as developed in 1914, which so far has not been done, but in addition to assume our part of an added burden, of undefined character and weight, if the reasonable expectations of a new governmental policy concerning ships and shipping are to be realized. The volume of oil in storage in the United States outside of California dropped 23,000,000 bbl. last year. It has dropped steadily for three years, and so have the Californian stocks, the two combined having lost 67,000,000 bbl. This continued descent must be arrested, or the consequences will be felt universally at no distant date.

What the War did, to emphasize in a broad way, to the value of crude petroleum is a subject of fascinating interest, and worthy of separate consideration. Suffice it to say, petroleum has become the most sought after of all raw materials, and at the moment the fight for the control of its sources of supply may be the subject of much maneuvering at the peace table in Paris.

AMMONIA is effectively separated from steam and tar contained in producer gas, and from this clean ammoniacal salts of any acid is obtained by passing the gaseous mixture, after it has been washed at a temperature of about 80° C. in water, which may contain lime, through a tubular or other condenser, arranged to act as reflux condensers, the part of the condenser at which the mixture enters being kept at such a temperature, for example 80° C., that the steam and tar are simultaneously condensed, but any ammonia which condenses with them is immediately volatilized. The other end of the condenser system is kept at such a temperature, for example 40° C., that practically all the steam and tar are condensed but not the producer gas and the ammonia, which are passed through a tar-separator to remove final traces of this material. The ammonia is then converted into any desired salt by passage through an acid, and the gas is left in a pure condition. Ammonia remaining in the condensate from the reflux condenser is volatilized by any known method. Two or more condensers in series or parallel may be used, and free spaces in which the gases and vapors are stated to mix may be arranged between the tube-plates of adjacent condensers. The air-blast for the producer may be heated by the water from the condensers. In one form of heating and saturating this blast with moisture, the blast is passed between two tubes forming the condenser, and the water is used in the form of a film or spray. This method constitutes the basis of a British patent granted to A. H. Lynn and N. E. Rambush (Brit. 119,049).

THE Yukon Gold Co.'s holding in Idaho covers several miles along Prichard creek. It has been sampled by drilling, and carries good value in coarse gold that resisted all former methods of treatment by reason of the flat grade of the creek and the depth of the gravel. It was freely predicted by old-timers that this deposit could not be successfully worked by dredging, on account of the rough bed-rock; but these difficulties have been overcome. The 7-cu. ft. boat is operating successfully. It is electrically driven by six motors, aggregating 300 hp., with current from the Beaver Creek district, 10 miles distant.

International Control of Minerals

By C. K. LEITH

*World Movement of Minerals. The annual world production of minerals approximates 1,700,000,000 tons, over 90% of which consists of coal and iron. Of this amount about two-thirds is used within the countries where the minerals are produced and one-third is shipped to other countries. The mineral production of the United States amounts to about one-third of the total. In the discussion of mineral resources in their international aspects we are concerned primarily with the 33% of the mineral output which moves between countries. It may be assumed that the consumption within the countries of origin is a matter of national rather than international concern.

One of the several interesting facts in this world movement of minerals is that the movement of most of them shows a remarkable concentration. For instance, manganese moves from three principal sources and converges at four or five consuming centres. Chromite moves from two principal sources: tungsten also from two. Even for certain commodities which are widely distributed and move in large amounts the concentration of movement is marked—for instance, the world movement of coal is controlled by the United States, England, and Germany. In other words, although the world movement of mineral commodities is widespread and exhibits many complex features, most of the individual minerals follow two or three salient lines of movement. This means in general that for each mineral there are certain sources of limited geographic extent, which, because of location, grade, relation to transportation, cost—in short, all the factors that enter into availability—are drawn upon heavily for the world's chief demands. The convergence of these materials toward a few consuming centres indicates generally concentration of coal production necessary to smelting, high development of manufacturing, large per capita use, concentration of facilities, strong financial control, and, not least, a large element of enterprise which has taken advantage of more or less favorable conditions.

Another significant fact which emphasizes the interdependence of nations and the importance of international considerations is that no country is entirely self-sustaining in its mineral requirements.

Movement of Minerals. If the world pre-war movement is considered broadly, it may be regarded as conforming essentially to normal trade conditions of supply and demand. There have been barriers to overcome, such as tariffs and trade controls and monopolies of various kinds, but these barriers have not prevented the major movements between the best sources of supply and the principal consuming centres. These movements may be regarded as a more or less spontaneous internationalization of mineral resources by private enterprise. The aim of free trade or unrestricted commerce was equality of trade opportunities, but such conditions of unrestricted competition tended to concentrate trade in the hands of the strongest interests and to prevent equality of opportunity.

The efforts made to promote or hinder international mineral movement by tariffs, bonuses, embargoes, subsidies, transport control, patents, Government management, financial pressure, and other means have been incited mainly by national or imperial self-interest and have thus been to some extent inimical to an internationalization based on the principle of the greatest good to the greatest number. It may be supposed that in any effort to attain supernational or international control, motives and measures based on national self-interest of the sort here mentioned will continue to play an important part. The question to be determined is the extent to which national interest can and will be subordinated to international interest.

Changes Due to the War. The War wrought fundamental changes in the world movement of minerals. The character and distribution of the demands changed. Customary sources of supply were cut off. Financial disturbances and ship shortage profoundly modified the nature, distribution, and extent of the world movement. Our domestic mineral industry was abruptly brought to a realization of its vital relations with international trade. To illustrate, the large movement of manganese from India and Russia to the United States was abruptly stopped, and we had to develop a source of supply in Brazil. The stoppage of pyrite importations from Spain as a means of saving ships required the development of pyrite and sulphur supplies in the United States. The export of oil from the United States to European countries was greatly stimulated, and the export to other countries was correspondingly decreased. The world movements of coal were vitally affected, principally by the limitation of the coal shipments from England and the United States to South America and the concentration of shipments to European countries. The closing of German coal supplies to near-by countries had far-reaching consequences. The cutting off of the German potash left the world for the time being almost unsupplied with this vital fertilizing ingredient. The Chilean nitrates, on which the world had relied for fertilizer, were diverted

---

*A paper to form part of 'Mineral Resources', 1917, of the U. S. Geological Survey. Mr. Leith has been serving as mineral adviser to the War Industries and Shipping boards, at Washington.

almost exclusively to the manufacture of powder. The total annual imports of mineral commodities into the United States were reduced by 1,200,000 tons. Our exports, though they continued in large volume, were mainly concentrated in Europe. The story of these disturbances in the world movement of minerals, though highly interesting, is too long to be told here.

INTERNATIONAL CONTROL. Out of these sweeping and rapid changes in the world movement of mineral commodities there arose, partly as cause and partly as effect, international agreements for the allocation of minerals, as a means of insuring the proper proportions of supplies to the different countries for the most effective prosecution of the War. Inter-Allied purchasing committees in London and in Paris found it necessary to make an inter-Allied allocation of the output of Chilean nitrate, because the sum of the demands exceeded the total supply by a considerable fraction, and to agree on distribution and price of the world's supplies of tin, tungsten, and platinum. For many other commodities agreements of various sorts were made. For instance, the United States entered into an agreement with England and France for the purchase of iron ore and molybdenum from Scandinavia to keep it out of Germany. The United States and England agreed as to supplying Canada with ferro-manganese. New problems of world allocation came up almost daily.

We now face the immediate and pressing question whether the centralized international control required by the War shall be retained or extended as a means of furthering the aims of a league of nations. When such a league was first proposed emphasis was placed mainly on political and military considerations. It now seems to be recognized that these are so closely interlocked with economic considerations that any league of nations, to be effective as a means of minimizing future international discord, must make provision for some degree of international or supernational control of business. Recent statements by officials of Great Britain and France seem to indicate a definite purpose to urge such control.

Some of the reasons which have been urged for the international control of the movements of minerals are as follows:

1. To ensure equitable distribution of certain minerals, such as tungsten, vanadium, platinum, and gold, of which there may be a world shortage.

2. To mitigate a world shortage of ships by international allocation of ship space, which would entail limitations on the movement of minerals.

3. To prevent nations which are more advantageously situated in regard to finance, location, and general control of trade from monopolizing the business in any commodity at the expense of other nations—in other words, to ensure equality of opportunity in regard to basic raw materials. The control of many mineral commodities now approaches national monopoly.

4. To reach some agreement as to division of markets for commodities such as iron, steel, and coal, which are available in so great abundance that several of the larger nations have considerable exportable surplus, in order to prevent international difficulties due to unrestricted competition.

5. To maintain equilibrium of price.

6. To ensure common and equitable contribution of supplies for rehabilitation of the devastated countries.

7. To serve as a means of disciplining any nation that will not conform to any code or control established by a league of nations. To many this has been a dominant consideration.

8. In general to prevent economic friction that might vitiate any world political agreements.

9. To replace the crude and cumbersome arrangements for international control through complex treaties and tariffs by a more centralized system.

The foregoing is merely a list of suggestions that have been made; it is not a unit statement of the requirements of the situation.

SPECIFIC PLANS. The various schemes proposed to meet these requirements centre fundamentally about allocation of supplies. There seem to be two main lines of approach to this problem. One leads to equality of economic opportunity through means expressed as follows by the League of Free Nations Association of New York:

(*a*) No State shall accord to one neighbor privileges not accorded to others—this principle to apply to the purchase of raw material as well as to access to markets.

(*b*) States exercising authority in non self-governing territories shall not exercise that power as a means of securing a priveleged economic position for their own nationals; economic opportunity in such territories shall be open to all peoples on equal terms, the peoples of nations possessing no such territories being in the same position economically as those that possess great subject empires. Investments and concessions in backward countries should be placed under international control.

(*c*) Goods and persons of the citizens of all States should be transported on equal terms on international rivers, canals, straits, or railroads.

(*d*) Landlocked States must be guaranteed access to the sea on equal terms both by equality of treatment on communication running through other States, and by the use of seaports.

The other main line of approach to the problem leads to definite international allocation of raw materials as a means of preventing the strong nations from crowding out the weak, an inequity which would be possible under even ideal arrangements for ensuring equal economic opportunities. More specifically it is proposed that the exportable surplus of selected minerals from the countries that enter into a league of nations shall be distributed as may be mutually agreed. This proposal means presumably continuance of Government control of international trade through licenses and ships. It means a curbing of private initiative and a sacrifice of the self-interest of the stronger in favor of the weaker.

The purpose of this paper is to discuss some of the specific relations of this arrangement to the mineral industry of the United States, that we may weigh the advantages and disadvantages of international control.

POSITION OF THE UNITED STATES. The United States is more nearly self-sustaining in regard to mineral commodities as a whole than any other country on the globe. The following statement summarizes qualitatively our position:

1. Minerals of which there is an adequate supply or exportable surplus in the United States:

A. Minerals of which our exportable surplus dominates the world situation:
    Copper.
    Petroleum.

B. Minerals of which our exportable surplus constitutes an important but not a dominant factor in the world trade:
    Sulphur.
    Phosphates.
    Silver.
    Iron and steel.
    Coal.
    Cement.
    Uranium and radium.

C. Minerals of which our exportable surplus is not an important factor in world trade. Small amounts of these minerals have been and will doubtless continue to be imported because of special grades, backhaul, or cheaper sources of foreign supply, but these imports are for the most part incidental:
    Lead.
    Zinc.
    Aluminum and bauxite.
    Gold.
    Tungsten.
    Molybdenum.
    Asphalt and bitumen.
    Pyrite.
    Barite.
    Fluorspar.
    Building stone (excepting Italian marble).
    Cadmium.
    Gypsum.
    Lime.
    Tripoli and diatomaceous earth.
    Mineral paints (except umber, sienna, and ocher from France and Spain).
    Pumice.
    Garnet.
    Salt (except special classes).
    Talc.
    Arsenic.
    Bismuth.
    Bromine.
    Artificial abrasives, corundum, and emery (except naxos emery).
    Fuller's earth.
    Mercury.

2. Minerals for which the United States demand must continue to be met by imports.

A. Minerals for which the United States must depend almost entirely on other countries:
    Tin.
    Nickel.
    Platinum and metals of the platinum group

B. Minerals for which the United States will depend on foreign sources for a considerable fraction of the supply:
    Antimony.
    Vanadium.
    Zirconium.
    Mica.
    Monazite.
    Graphite.
    Asbestos.
    Ball clay and kaolin.
    Chalk.
    Cobalt.
    Naxos emery.
    Grinding pebbles.

3. Minerals normally imported into the United States which in future can be largely produced from domestic sources if it seems desirable:

A. The following minerals were mainly imported before the War, but under war conditions the domestic resources have been developed to such an extent that the United States can become self-sustaining if desirable, though at so great a cost that a protective tariff will be necessary if these industries are to survive:
    Nitrates (except potassium nitrates).
    Potash.
    Manganese.
    Chromite.
    Magnesite.

No attempt will be made here to present the detailed figures on which the above generalizations are based. In view of the present disturbance in production and consumption, any judgment as to future demands or available surplus must take into account several factors which cannot be accurately measured, such as financial control in foreign countries, possible tariffs, and foreign competition. For this reason the above statement should be regarded as only tentative, though it is the result of a rather exhaustive study of conditions in relation to the world control of shipping. The classes named overlap to some extent, and it is to be expected that some of the commodities placed in one class may in the near future be transferred to another.

GENERAL CONCLUSIONS. 1. It is clear that a league of nations offers but little advantage as a means of ensuring adequate supplies for the United States, and that the limitations on the distribution of exportable mineral supplies would probably weigh more heavily on the United States than on any other country. The few minerals for which the United States is dependent on foreign countries are offset by so many in which we have a dominance of supply and our financial position is so strong that it appears certain that the United States does not need the aid of a league of nations to ensure adequate supplies even of these few minerals. In short, in this respect our entrance into a league of nations would not be based on self-interest. We would sacrifice to some extent an independent and dominant position. In our dealings with other nations this fact should give weight to whatever emphasis the United States may wish to put on the desirability of international control of minerals. At the same time it imposes a hard task on the United States to arouse the mineral interests to the support of a measure that involves so much self-sacrifice. The value of our annual potential exportable surplus of minerals approximates a billion dollars; that of our necessary mineral imports about $175,000,000. Our active allies, Great Britain, France, and Italy, together have a maximum annual exportable surplus worth perhaps $325,000,000, and their necessary imports amount to $265,000,000.

2. It seems clear that our effort to make this country entirely self-sustaining in regard to raw materials, which has been especially marked during the War, will need to be modified if we are to adapt ourselves to conditions of international control. Although we may be able to become self-sustaining in respect to essential commodities like manganese, chromite, and potash, by so doing we are cutting off the export market of other countries where these commodities exist in such quantities and grades that they would be, under conditions of free trade, our principal sources of supply. By drawing on such sources we not only get a cheaper and higher grade of product, but we develop a return market for the products in respect to which our natural advantages entitle us to a share in the export trade. The potash situation will illustrate the problem. The War cut off German supplies. We made every possible effort to meet the deficiency. Prices rose tenfold. Now, are we to continue this effort at high cost? Our instinctive answer is, Yes. But suppose at the peace table it is mutually agreed that for the welfare of France and Spain we should absorb a certain part of their output, or even that we should take German potash as an indirect way of collecting indemnity? This question is put for the purpose of making the problem concrete, and no answer is attempted here, though I venture to suggest that the practicable course will be found to lie between the two extreme alternatives.

If all countries take the stand that they must be self-sustaining in regard to natural resources, they can accomplish their purpose only by high artificial barriers to offset inequalities in the factors which determine the availability of the several commodities, with the result that the world movement of raw materials will be greatly lessened. Instead of free circulation of essential basic commodities vitalizing any world agreement there will be a series of compartments in which trade is maintained at different levels, under different pressures and conditions—a situation difficult to maintain and inimical to world agreements based on mutual concessions. It is clear that if each of the States of the United States should adopt the principle of making the State self-sustaining in minerals so far as possible, the result would be to increase largely the chances of interstate friction and to lower efficiency in the United States as a whole.

3. Following President Wilson, the League of Free Nations Association, before quoted, states: "Equality of economic opportunity does not mean the abolition of all tariffs or the abolition of the right of self-governing States to determine whether free trade or protection is to their best interests." If the view expressed in conclusion 2 is correct, it follows that the United States, as a member of a league of nations, would not be free to impose tariffs dictated by national self-interest beyond such minor duties as might tend to equalize the labor element of cost of production. Also, when we remember the remarkable degree to which many of the leading mineral commodities are geographically concentrated, it is clear that a tariff on any particular commodity will usually affect mainly some one or two foreign nations—a result which does not accord with the principle that a State shall not give to one neighbor privileges that it withholds from others.

More might be said for a temporary tariff designed to let down easily, for example, the manganese, chromite, and potash industries, which face large losses because of overdevelopment to meet war needs. The Mineral Act perhaps might be used for this purpose. If this principle were adopted for a few minerals, however, it probably would soon be extended to others and into more general non-mineral fields, thereby presenting a problem of enormous difficulty.

In passing it may be noted that as long as shipping is inadequate, as it may be for some years, high and slowly declining freight rates may serve much the same purpose as a tariff for low-priced commodities of much bulk, like manganese, though not for high-priced commodities like tungsten.

Something might also be paid for tariffs intended to ensure the smelting of ores and their conversion to usable forms within the country of origin, thus reducing the tonnage to be transported and supporting the largest industry within the country; but it must be remembered that the distribution of coal resources and centres of production marks certain world centres of smelting and manufacturing, which are entitled by natural advantage to an unhampered movement of raw materials from other countries.

The question of protective tariffs is becoming acute at present, owing to the release of the restrictions imposed by the War Trade Board as a means of saving ships.

4. The interests of conservation clearly call for an international viewpoint in the handling of our mineral resources. The deposits of most minerals are so highly concentrated in their distribution and general availability that the principal sources for the world are in comparatively few places. When all factors of conservation are taken into account, including labor and efficient use of the product, it would seem that the minerals

should be drawn from these natural sources of supply. To illustrate, the chromite and manganese deposits of the United States are relatively small and of low grade as compared with other sources of supply. Insistence on the use of the domestic material would mean early exhaustion of local supplies, lowered efficiency in use, and higher cost. As cost includes not only the intrinsic value of a product but items for labor and transportation, it appears that the use of these domestic materials means a higher expenditure of human effort than is necessary.

There is perhaps as much need of specializing in mineral output as there is of specializing in manufacturing. The thought that every country on the globe should be self-sustaining in regard to mineral supplies is of somewhat the same order as the thought that every family should produce all its own raw materials rather than take advantage of the more favorable conditions existing elsewhere and so specialize in human effort. If for a certain amount of capital and labor we can produce copper more cheaply than any other country and thus dominate the world's markets, it is not economy to divert this capital and labor to the production of ores of manganese or chromite, which because of natural conditions can be produced much more cheaply elsewhere.

Extension of international control of minerals seems to offer possibilities of loss and gain—loss through a considerable sacrifice of national trade and a narrowing of the field for private initiative in trade; gain through the possibility of attaining certain ends which are attainable only by international agreement, such as an allocation of supplies which will be to the advantage of the greater number of nations rather than to the advantage of the few that are strong enough to dominate the situation and which will in general prevent economic friction from endangering a league of nations based on political and policing considerations.

In a world governed by good-will the effective internationalization of trade might well be gained by leaving trade unrestricted. In proportion as the actual condition may depart from this ideal condition, some sort of international agreement as to control seems justified. Such control would by no means eliminate international rivalries and jealousies; it would transfer them to the international governing body. The duties of such a body would be onerous and perplexing. It might even be supposed that nationalistic aspirations might be so strenuously presented and so firmly backed by national steps in the way of embargoes and protective tariffs that the international control would amount to little. But it may be further supposed that a league of nations whose members enter into it voluntarily and with mutual good faith might control the situation sufficiently to bring recalcitrant members into line. The questions thus suggested are difficult to answer.

6. It is sometimes argued that any attempt to control the movement of raw materials, for whatever purpose, defeats itself because it leads to the automatic development in the restricted area of increased exploration, new sources of supply, substitutions, etc. Restriction unquestionably has this effect, but nevertheless such measures are expensive makeshifts and offset the effects of limitation only in part, as is clearly proved by the experiences of the War.

7. The purpose of this paper is primarily to state the problem of international control of minerals, rather than to present an argument for it. Such control entails difficulties which are especially burdensome on the United States and which at present may be insuperable. The interests of conservation clearly require international control. Moreover, the lesson of the War points to the necessity of overhauling old international understandings and machinery, even though such a task would encounter great difficulties, not the least of which lie in the persistence of human habits and inertia Whether the time has come to establish a league of nations with economic control can be determined only by our individual and collective answers to the question whether we are willing to make the necessary economic sacrifices, individually and nationally, in the interest of world harmony. The mineral industry should fully understand that with international control efforts to promote export will need to be modified and curtailed; that expansion of our trade in many lines will mean equivalent loss of trade to other nations; that the almost universal conception that expansion of foreign trade is a meritorious aim and end in itself, without regard to its effect on other countries, will need revision. It is necessary only to cite the present movement to create great export associations under the Webb Act to show that present tendencies for definite action do not take into account the possible conflict of such action with the economic requirements of a league of nations.

8. Whatever action may be taken in regard to international control, it is clear that the War has brought the United States into such world relations that it has become imperative for us to study and understand the world mineral situation much more comprehensively than before, in the interest not only of intelligent management of our own industries but of far-sighted handling of international relations. When the European war began we found our mineral industries vitally affected by international developments which we only partly understood. Government mineral organizations, as well as those outside the Government, had given relatively little attention to foreign mineral resources and markets. Information and statistics were scattered and incomplete. Under the stress of war the Government, especially the Geological Survey, the Bureau of Mines, and the several war boards, found it necessary to use extraordinary efforts to obtain even elementary information on the international features of mineral trade. Much progress has been made, but only a start. I would like to make a plea for definite recognition of the necessity of a systematic study of the world's mineral resources from the world's standpoint to supplement the studies made of the domestic resources, both by the mineral industry itself and by governmental and other agencies.

Pioneer Life in California—A Review

By GRANT H. SMITH

"Whoever wants merely an eulogistic story of the glories of the pioneer life of California must not look for it in history, and whoever is too tender-souled to see any moral beauty or significance in events that involve much foolishness, drunkeness, brutality, and lust must find his innocent interests satisfied elsewhere. * * * Early California history is not for babes, nor for sentimentalists; but its manly wickedness is full of the strength that, on occasion, freely converts itself into an admirable moral heroism," says Josiah Royce, in his painstaking and philosophical inquiry into the lives and manners of the early Californians, entitled 'California, A Study of American Character'.

Whoever is interested in that period should read Professor Royce's book; in it he will find the true background for the history of the State. Some of the glamor and romance will be gone, it is true, but the thoughtful reader will have a new and better understanding of California's period of stress and travail, and of American character.

The book was a labor of love to the author and he brought exceptional qualifications to the task. The son of pioneer parents; born and reared in one of the early California mining camps; a graduate of the University of California, and later assistant professor of philosophy there; afterward famous as a professor of philosophy at Harvard—one of the clearest and most original thinkers of his time.

So much unreal and exaggerated stuff has been written of the lives of the Pioneers, that it is a deep satisfaction to find a book on the subject by a rarely competent and sympathetic author, which bears on every page the impress of research, wise discrimination, and a desire to arrive at the truth.

In outlining his picture, Royce says:

"We are to deal with a California that was to be morally and socially tried as no other American community ever has been tried, and that was to show, as we Americans have not elsewhere so completely and in so narrow compass shown, both the true nobility and the true weakness of our national character. All our brutal passions were here to have full sweep, and all our moral strength, all our courage, our patience, our docility, and our social skill were to contend with these our passions."

Of the success of the fortune-hunters we read:

"From that land many of them would indeed return, more or less defeated, poor and broken-spirited; many would die early deaths; the survivors would for the most part stay in the new land as hard toilers and poor men; a few only would reap great fortunes, and of these few only a part would ever again see the old home. The average net income per man throughout the whole mining community, even in the best days, was, in view of the high expenses of living, seldom more than equal to treble the wages of an unskilled day laborer at home, and was usually much less than that."

As a trained sociologist, the author dwells upon the fact, seldom noticed by earlier writers, that the social condition of the camps was, in the successive years and despite all good intentions, largely and almost irresistibly determined by the various successively predominant methods of mining; namely, the pan, the rocker, and the sluice.

Washing gravel with a pan was almost the only method of mining at first. This was slow and tedious and economically wasteful; none but rich and accessible gravel would pay; even when found, such diggings were soon exhausted; men were constantly on the move, and necessary supplies difficult to obtain. Worse still, from a sociological point of view, each man worked for himself and by himself; there was no community of interest. Pan-mining, the author finds, was a social deterrent, because tending to a selfish, roving, hazardous, and irresponsible life. Mining life, on the whole, in 1848, was seriously demoralizing to all concerned in it and remained so until more elaborate methods of mining could be introduced.

In the latter part of 1848, the rocker came into general use. The effect, socially and materially, was remarkable. "Gravels that the pan-miner contemptuously abandoned were well worth working on this plan. Camps that would have been deserted remained and were prosperous. The great thing, however, * * * was that men now began voluntarily, and in an organized way, to work together. The miners' partnership, which grew up in this second stage of mining life, soon became one of the closest of California relationships, and, as such, has been widely and not unjustly celebrated in song and story."

The small partnership and cradle system of mining was the common practice in 1849, and in the early part of 1850. After several improved rockers had been tried with varying success, the 'long tom', a large and efficient rocker, came into general use in 1850; and, a little later, that finely simple invention, the board sluice, revolutionized the whole business of placer-mining.

"The introduction of the sluice, with its various auxiliaries, not only secured the productiveness of California placer mines for many years, but it acted indirectly on society, as a check to the confusion and disorder that began to grow among the miners in 1850 and 1851."

Social life was still further stabilized by the great enterprises that were undertaken in the early 'fifties for building flumes and ditches to bring large volumes of water for long distances to the mines, and by the river-mining enterprises. River-bed mining was early undertaken on a small scale, and on a large scale, but with general disaster, in 1850. The season of 1850-1851 was the dryest in the history of California, the rivers were low and remained so for many months, and river-bed mining became and remained for a number of years a great and fruitful industry.

"It was one of the boldest and most dramatic of the miner's great fights with fortune. He had to organize his little army of laborers, to risk everything, to toil nearly through the summer for the hope of a few weeks at most of hard-earned harvest at the end; and often, at the very moment when victory seemed nearest, an early rain swept everything away, and left absolutely no return. In this type of mining, whose operations have been very frequently described, the object was to turn the course of some one of the greater mountain-streams, by means of a dam and a canal or flume. The bed would thus be left bare, perhaps for miles, while the flume carried along the whole body of the stream, whose impulse was meanwhile used to turn water-wheels in the flume, and so to pump from the stream-bed the surplus water that still interfered with active operations."

Many pages of the book are devoted to an inquiry into 'miners' law' and 'lynch law', which Prof. Royce distinguishes; although he says that of the sharp line of demarcation between the two, the miners themselves seemed at the time to be largely unconscious. 'Miners' law' was open in its methods, liked regularity of procedure, gave the accused a fair chance to defend himself before a jury of his fellows, and was carried out in broad daylight by men publicly chosen. 'Lynch law' needs no definition.

"The California newspapers of 1850, 1851, and 1852 generally defend miners' justice; but they show us two things, first, that the miners' justice was not usually sharply distinguished from mob law, even in the minds of those concerned in it; and secondly, that, in the concrete instances of the use of miners' justice, we can discover all possible gradations from the most formal, calm, and judicial behavior of a healthy young camp, driven by momentary necessity to defend itself against outrage, down to the most abominable exhibitions of brutal popular passion, or even of private vengeance. * * * I wish that the latter class of incidents had been rarer than one actually finds them."

The ill treatment of all foreigners by the miners is most severely criticized by Royce. He says:

"The fearful blindness of the early behavior of the Americans in California towards foreigners is something almost unintelligible. The avaricious thirst for gold among the Americans themselves can alone explain the corruption of heart that induced this blindness."

The American miners deeply resented the presence of foreigners in the diggings, and frequently declared that only citizens of the United States were entitled to own and work mines. Cases were not infrequent where peaceable foreigners were driven from their claims, which were promptly appropriated by the aggressors. The Mexicans, who were numerous in the southern camps, came in for particularly shameful treatment. Apparently they had no rights that anybody was bound to respect, although until a few short years before, this land had been theirs and we had taken it from them, in what many fair-minded men believe to have been an unrighteous war

"The foreigners were often enough degraded wretches, such drank, gambled, stole and sometimes murdered; they were also, often enough, honest fellows, or even men of high character and social positions; and such we tried in our own way to ruin. In all cases they were, as foreigners, unable to form their own government, or to preserve their own order. And so we kept them in fear, and, as far as possible, in misery. * * * We did not massacre them wholesale, as Turks might have massacred them: that treatment we reserved for the defenseless Digger Indians, whose villages certain among our miners used on occasion to regard as targets for rifle practice, and as subjects for other brutal abominations."

The compiler of these paragraphs, himself the son and the grandson of pioneers, has no desire to rob the early days of their romance, nor reflect upon the character of the men that, on the whole, set a great impress upon the State; but, like the author, he believes that the truth should be told, not only for its own sake but in order that we may have a right understanding of the history and development of this glorious State. As Royce says:

"Everything that has since happened in California, or that ever will happen there, so long as men dwell in the land, must be deeply affected by the forces of local life and society that then took their origin."

The chapter on 'Social Evolution in San Francisco' is particularly interesting and illuminating. Elsewhere the struggle for the cause of progress in California was either in the mining camps or in the rural districts, but upon the success or failure of law and order in San Francisco, the centre of the State's mental and political life, the future of California was dependent.

Necessarily the author deals at length with the two remarkable vigilance committees of San Francisco. Of them he says:

"Not the same judgment, by any means, can be passed upon the San Francisco vigilance committees of 1851 and 1856 as we have already passed upon the popular justice of the miners. In some respects, to be sure, there is an unfortunate likeness. Both in the mines and in San Francisco, carelessness had led to a destructive general license of mischief-makers. In both places the men of sense were forced at last to attend to their social duties. But in the mines there was, for a while, a far too general, a very absurd and wicked, trust in lynch law as the best expression, under the circumstances, of the popular hatred of crime. San Francisco, as a community, never went so far as this. In that city lynch law was, both in 1851 and in 1856, the expression of a pressing desire so to reform the social order that lynch law should no longer be necessary."

"What had made it [the second vigilance committee] inevitable was a long continued career of social apathy, of treasonable public carelessness. What it represented was not so much the dignity of the sovereign people, as the depth and bitterness of popular repentance for the past. What it accomplished was not the direct destruction of a criminal class, but the conversion of honest men to a sensible and devout local patriotism. What it teaches to us now, both in California and elsewhere, is the sacredness of a true public spirit, and the great law that the people who forget the divine order of things have to learn thereof anew some day, in anxiety and pain."

"The great committee [of 1856] was productive of more good than evil only because in the sequel it was not left to its natural tendencies, but was constantly guided by cautious and conscientious men, whose acts were not always wise, but whose purposes were honest and rational. * * * The first real test of the success of the committee in its one true work, which was to agitate for a reform in municipal society and politics, came at the autumn elections, when the people sustained the whole movement by electing city officers to carry on in a legal way the reform which had been begun without the law. And thenceforth, for years, San Francisco was one of the best governed municipalities in the United States.

Determination of Sulphuric Acid

*It is possible to estimate H_2SO_3 and $H_2S_2O_3$ in the presence of each other, by first determining both iodometrically, and then the H_2SO_3 by a method based on the reaction $Na_2S_2 + Na_2SO_3 = Na_2S + Na_2S_2O_3$. This change takes place rapidly near the boiling temperature, and is further accelerated by the addition of NH_4Cl. The persistence of the yellow color of the reagent serves as a satisfactory end-point. To prepare a normal solution of Na_2S_2, saturate 500 cc. normal NaOH with H_2S, remove the excess gas under diminished pressure, add an equal volume of normal NaOH, then dissolve in the cold solution, 16 gm. of sulphur crystallized from CS_2. To the flask containing the solution join a burette by means of a siphon, and connect both with a gas holder of nitrogen for displacing air from the system. Standardize the Na_2S_2 solution gravimetrically. Measure 20 cc. into a solution containing AcONa and a slight excess of AcOH, expel H_2S by boiling in a current of CO_2, collect the sulphur on a filter of tared glass-wool, dry in vacuo over H_2SO_4 and weigh. The small amount of thiosulphate always present in the solution of Na_2S_2 can be determined iodometrically, and the necessary correction applied. The greater the dilution the more rapid is the titration and the more definite is the end point. However, it is not advisable to have more than 100 cc. per 5 cc. of reagent. Under these conditions each 100 cc. should contain 5 cc. twice-normal NH_4Cl and should be slightly alkaline (alkalinity equivalent to 4 cc. normal Na_2CO_3 per 50 cc.). A current of CO_2 should be kept passing over the surface of the liquid during the titration, which should require less than 10 minutes, especially if the approximate titration has been ascertained by previous experiment. If trithionate is present, the situation is more complicated. Trithionate is not acted upon by iodine in the cold but it is converted into thiosulphate by Na_2S, thus: $Na_2S_3O_6 + Na_2S \leftrightarrows 2Na_2S_2O_3$. This reaction is slow in the cold, but is rapid at higher temperatures; in the presence of Na_2S_2, sulphur is precipitated. Heat a dilute solution with a slight excess of Na_2S or Na_2S_2, in presence of NH_4Cl, for several minutes near the boiling point, add AcONa and a slight excess of AcOH; heat for 15 minutes in a current of CO_2, then titrate with tenth normal iodine. Results are good; 0.1785 gm. $K_2S_3O_6$ requires 13.25 cc. tenth normal iodine. In the case of a mixture of sulphite and trithionate, the Na_2S_2 produces both changes simultaneously: $Na_2SO_3 + Na_2S_3O_6 + Na_2S_2 \leftrightarrows 3Na_2S_2O_3$. If trithionate is present in excess, it is shown by a turbidity due to sulphur which appears after the sulphite is consumed. The turbidity does not interfere with the end point, as the yellow color of the reagent is readily observed. A mixture for analysis contained 5 cc. $Na_2S_2O_3$ solution corresponding to 4.80 cc. tenth normal iodine; 2 cc. Na_2SO_3 solution corresponding to 9.19 cc. tenth normal iodine and to 1.84 cc. Na_2S_2; 0.1337 gm. $K_2S_3O_6$ corresponding to 9.88 cc. tenth normal iodine. Titration of this mixture required 1.90 cc. Na_2S_2 and 24.00 cc. tenth normal iodine. An alternative method for trithionate is based on the titration of the residual iodine after heating with excess of iodine under pressure. This follows the titration of sulphite and thiosulphate in the cold. The tetrathionate from the latter is then changed to sulphate, as is the trithionate. The principle appears to be sound, but there are many sources of error. Another procedure for determining trithionate employs the action of heat; $H_2S_3O_6 \leftrightarrows H_2SO_4 + SO_2 + S$. Acidify the solution by adding HCl, heat near the boiling point in a current of CO_2 until SO_2 is all expelled (end of operation being detected by dipping the end of the delivery tube into dilute iodine solution), filter off the sulphur and precipitate the H_2SO_4 with $BaCl_2$. Investigation showed that the precipitate thus obtained contained 97.9–97.5% of the trithionate, which was converted into sulphate. In the presence of H_2SO_3 and $H_2S_2O_3$ the loss is more or less compensated by the unavoidable oxidation of the H_2SO_3. If H_2SO_4 is also present, it is of course precipitated. A known mixture containing 0.3457 gm. K_2SO_4 (1.982 millimols) with 0.1315 gm. $K_2S_3O_6$ (0.486 millimol) also 1.813 millimols of $Na_2S_2O_3$ and 2.445 millimols Na_2SO_3, gave on analysis 2.485 millimols of trithionate and sulphate (100.7% theoretical). In dealing with a mixture of all four acids, oxidize with bromine water, precipitate with $BaCl_2$, and thus obtain total sulphur as sulphate. The determinations outlined above then complete the data for calculation of the four constituents. In titrating trithionate by iodine and Na_2S_2, and determining $H_2SO_4 + H_2S_2O_3$ gravimetlically, H_2SO_4 is thus obtainable by difference. The determination of total sulphur serves as a check.

---

*O. Billeter and B. Wavre, Helvetia Chim. Acta, I, 174-80, (1918).

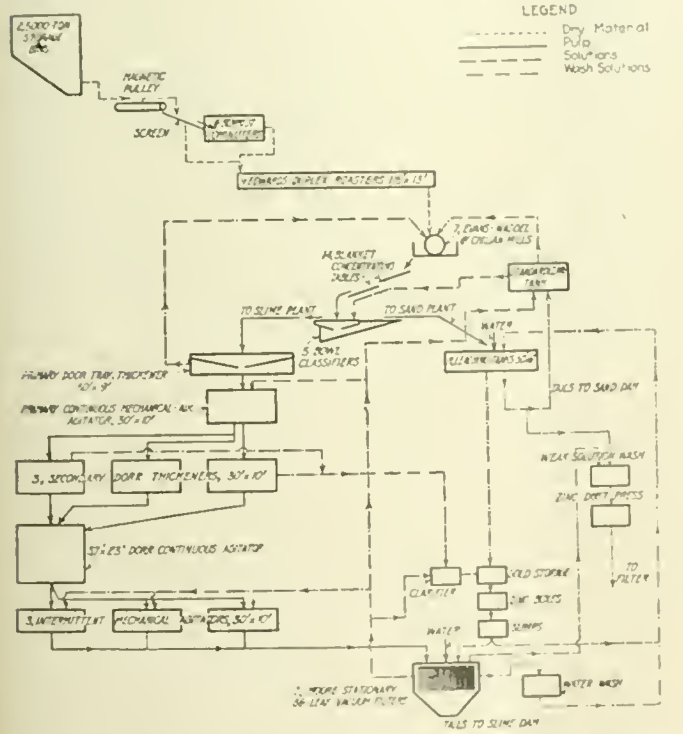
REVIEW OF MINING

CRIPPLE CREEK, COLORADO

Gold Production, Dividends, and General Notes.

Gold production of the district for the short month of February was curtailed by the weather, deep snow preventing movements of ore, both by team and by rail. The tonnage reported from the treatment plants fell to 75,350, with an average value of $8.46 per ton, and gross bullion value of $647,500, shown as under:

	Tons	Average value	Gross value
Golden Cycle mill, Colorado Springs......	23,000	$20.00	$460,000
Portland, Independence mill, Cripple Creek	37,000	2.06	77,250
Vindicator mill	13,000	2.20	28,000
Smelters, Denver and Pueblo............	1,850	55.00	81,750
Total	75,350	$8.46	$647,500



FLOW-SHEET OF GOLDEN CYCLE MILL AT COLORADO SPRINGS, WHERE NOTHING BUT CUSTOM ORE FROM CRIPPLE CREEK IS TREATED, (CHEM. AND MET. ENG.)

Dividends in February totaled $167,000, as follows: Cresson, $122,000; Golden Cycle, $45,000.

The Midget mine on Gold hill, the Blue Bird on Bull hill, and the Rose Nicol on Battle mountain will re-enter the shipping list during March.

Litigation between the El Paso Consolidated and the Katinka company over extra-lateral rights has been averted by settlement out of court. Operations will now be resumed at the Nichols shaft on the north end of the El Paso estate. Machinery had been removed from the shaft-house but a powerful electric hoist is to take the place of the steam engine.

The 25th annual report of the Portland company, presented to shareholders at the meeting, at which the officials were all re-elected, shows a net profit of $196,598 for 1918 [An abstract of the report appears in another part of this issue]

Driving on the 11th level of the Cresson shaft for a distance of 100 ft. has exposed a network of veins of high value, according to the general manager, A. L. Blomfield Driving is also in progress on the 9th and 10th levels, on the same orebody, and assays are 2 oz. per ton from grab-samples.

During the past week the tonnage treated at the mill of the Golden Cycle company at Colorado Springs has averaged 1000 tons daily, compared with 700 tons the last quarter of 1918. The increase is directly due to increased activity, made possible by the return of miners, discharged soldiers, and others to the district, and consequent relief of the labor shortage.

The lessee of the Deerhorn mine of the Stratton company, W. C. Green, has been honorably discharged from the U. S. Army and has resumed work.

Returns from a carload shipment of oro from the recent discovery made by Hamilton and son in the Gold Bond tunnel on Gold Hill gave $17.70 per ton. The lessees report improvement in value as the drift is extended.

The Komat Leasing Co., operating the Victor mine on Bull cliffs, under lease from the Smith-Moffat Mines Co., is shipping from three to four cars per week of milling ore. The January production was 400 tons, averaging $12.50 per ton.

Articles of incorporation have been filed for the Cocks Mining & Leasing Co., with a capital of $10,000. The directors are Frank W. Cocks, Roswell P. Russell, and Henry C. Cassidy of Colorado Springs.

DENVER, COLORADO

The Portland Company.—Potash from Mill Tailing.—Gas in Cripple Creek Mines.—Radium Companies and the Affair at Jimtown.—Colorado School of Mines.

Annual reports of mining companies are interesting mainly in data regarding expenses, production, development, and profits, but the last report of the Portland Gold Mining Co. [detailed on another pago of this issue], in addition to such statistical matter, presents several items having a bearing upon the status of the Cripple Creek district. Corroborating what has been said in the press and in public discussion, the troubles of a gold-mining concern last year are effectively exhibited in a comparison of the net profits of this company during the last two years. In 1917 the profit was $663,254, while in 1918 it was only $196,596. This drop of approximately 70% in a single year is significant material for the war economist. The president, Frank G. Peck, hints at re-opening the company's mill at Colorado Springs. He also briefly explains that Federal chemists spent nine months of last year in developing a process for recovering potash from the residue at this same mill. Sampling and measurements show about 2,000,000 tons averaging 7% K_2O. Still another item in this report states that the Portland's share in the cost of the Roosevelt drainage-tunnel was $144,951.

Salvage of potash from gold-mill residue is the object of the International Potash Corporation composed of Omaha and Lincoln capitalists, who have secured a lease from the Morse Bros. Machinery & Supply Co. on the 6,000,000-ton dump at the dismantled mill of the United States Reduction & Refining Co. near Colorado Springs. Chemists have decided that the dumps average 11% potash. Answering an inquiry into the discrepancy between the potash content of the dumps at two mills treating ores from the same district, the explanation has been offered that the United States mill tailing was mostly made at a period when the ore was subjected to different treatment from that subsequently practised in the Portland mill. A new plant, 125 ft. square, costing approximately $100,000, is being erected and is expected to be in commission by May 1. The process is one developed by professors of Johns Hopkins University and goes by the name of that institution.

The peculiar effect of atmospheric conditions upon mining in the Cripple Creek district is again brought to our attention in two fatalities that resulted on February 12 in the Midget mine. During a heavy snowstorm the barometric pressure became so low as to permit an undue amount of the residual nitrogen gas from the extinct volcano to exude into the workings. Such phenomena were discussed by Lindgren and Ransome in Professional Paper 54 of the U. S. Geological Survey, published in 1906.

Denver seems destined to become the centre of the world's supply of radium. This city was selected several years ago as the site for the plant erected and financed by the National Radium Institute, but operated by the U. S. Bureau of Mines. This relationship continued a sufficient time to demonstrate amply the success of a process proposed by the Bureau and to make a total extraction of more than six grams of radium. The plant was closed down when the Bureau moved its Colorado branch from Denver to Golden. Recently this complete plant has been purchased by the Minerals Recovery Co., whose officers are P. H. Chambers, president; W. W. Anderson, vice-president; and William E. Bryan, secretary and general manager; all of Denver. Your correspondent is informed that the company is fully financed and will soon engage in the commercial treatment of four tons of carnotite ore daily.——The name of the established and highly successful Schlesinger Radium Co. has been changed to the Colorado Radium Co. This company is steadily expanding its operations, its gross production last year being in excess of $1,000,000. Its product is assured a constant market in the manufacture, by the subsidiary, the Cold Light Manufacturing Co., of luminous articles.——The Chemical Products Co., incorporated a few years ago by Denver men and occupying the old paper-mills, has changed ownership, but it continues its reduction of radium from carnotite ore.——Finally we come to the project of the widely-advertised Colorado Pitchblende Co. with plans for extensive treatment of uranite-bearing fluorite mined at Jimtown, Colorado, although the milling and concentration of the crude ore will be done near the mines, the refining will probably be done at Denver.

Speaking of the Colorado Pitchblende Co. one finds good reading in newspaper accounts, more or less accurate, of incidents connected with the publicity campaign conducted by the company's officers. The 'Mining and Scientific Press' has published several items regarding this scheme, but the following sketch is offered to bring the story to date:

The first offering of shares in this company was with so much full-page newspaper advertising, and such extravagant statements regarding reserves and grades of ore, that public suspicion was promptly aroused and efforts were made to suppress the company's sales. Subsequently the promoters disclaimed any motive of exaggeration and 'passed the buck' for the flambouyant ads to a local advertising agency which is accustomed to handle publicity matters for new oil companies having few scruples. Last year the Denver City Council passed and enforced an ordinance that accomplished results in eliminating many questionable promotions by conducting official investigations of all concerns offering shares to the public. The bearing of this ordinance upon the project of the Pitchblende company was such that the president and general manager, J. F. Barnhill, personally urged an official investigation of his project, and ceased all efforts at selling shares pending such investigation. At that time the city's mayor was ill with influenza and nothing along this line could be done officially by the city government, so Mr. Barnhill turned his attention to the representative commercial organization of Denver. His attitude was so emphatic and serious that he prevailed upon the Denver Civic and Commercial Association to conduct a thorough examination of his project. The matter was immediately referred to the Manufacturers Association and the Mining Bureau, both sub-divisions of the C. and C. Association. Each subsidiary selected a well-known local mining engineer who went to Jimtown and rendered a professional report at the company's expense. M. S. MacCarthy was the engineer appointed by the Manufacturers Association, while James S. McClave was the choice of the Mining Bureau. These gentlemen co-operated in their work at the mines and mill and during their later experimentation at Denver, but they rendered separate reports which, while in substantial agreement, differed slightly in details. They reported affirmatively. Mr. MacCarthy delivered his report to the chairman of the Manufacturers Association, and it was then promptly handed over successively to the parent association and to the Pitchblende company, thereby directly giving the Association's endorsement to the promotion. However, Richard A. Parker, a prominent mining engineer and chairman of the Mining Bureau, upon his receipt of the McClave report, withheld it for more than a week during which period he not only critically studied it himself but caused it to be discussed in detail by a gathering of some 30 mining engineers. The idea back of this criticism was that the Civic and Commercial Association, particularly its mining branch, should not endorse any promotion until the project could be weighed with the same conscientious consideration that a professional engineer gives to a case for a private client. During this delay the company instituted suit for the possession of the McClave report, but the suit was dropped, with reluctance, Mr. Parker finally relinquished the report to the manager of the main Association, and it thereupon was delivered to the Pitchblende company. Immediately after the company's receipt of each report, large display advertising was resumed in newspapers, the extravagant statements in former space being replaced by I-told-you-so sarcasm. Agreeable to promise, both reports were printed verbatim: without any such promise, the reports would have appeared. The advertisements played up certain paragraphs of the reports in large bold type. The discussion at the gathering of engineers tended to prove that, admitting the tonnages and gross value given in the two reports, the profits to be expected from the contemplated commercial operations of the company were erroneous; that the daily handling of 1000 tons of crude ore would soon flood the nation's fluorspar market; and that the estimated costs of producing radium salts from carnotite ores did not apply to the rather complex ore involved in this project. These criticisms were not directed in any measure at the integrity of the examining engineers, but were proposed as the differing viewpoints of impartial critics. No representative of the company was present at the lengthy session of the engineers, although Mr. McClave was the leading person, and endeavored to explain every question put to him in an absolutely frank manner. No reporters were present, either, but one newspaper presented an account of the meeting, accompanying the account with insinuations that the opposition to the reports emanated from the Boulder Commercial Association which, in turn, was dominated by Prussian interests—an imputation wholly without a vestige of warrant. It is true that the Boulder people, including State Geologist R. D. George and Warren Bleeker, participated in the opposition, but this was purely upon technical grounds. In the Jimtown ore, fluorite, the principal mineral, is associated with very small amounts of gold, silver, lead, and iron, the ore being of sulphide character. During the dressing of the fluorite to raise it to a marketable grade, a streak of mineral heavier than galena was seen on the tables. Investigation proved this thin streak to be pitchblende, but, in practice, it was found next to impossible to effect a clean table separation of this mineral from the sulphides. However, the research conducted at Denver by the examining engineers (Mr. McClave has long been a flotation engineer) upon large samples secured during the mill-runs at Jimtown proved that a clean separation can be effected by oil flotation. It was doubt upon this subject that caused most criticism by various engineers who discussed the report. The reports show that the daily dressing of 1000 tons of crude ore will yield a gross production per ton as follows: gold, silver, and lead, $1.04; fluorspar, $3.81; uranium oxide and radium, $7.09; total $11.94. The operating costs being estimated at $2.80, the profit per ton will be $9.14. Corresponding figuring upon a basis of 100 tons daily gives a profit of $17.27. The wide discrepancy between these estimated profits arises because of assumed different market prices for the fluorspar, the figures on the smaller tonnage being based on present prices around $19 per ton for 85% grade, while the figures on the 1000-ton basis admit a post-war price for fluorspar of only $10 per ton. The affair thus far has consumed two months. It is rumored that the end "is not yet." Your correspondent desires to say here that he was among the most skeptical regarding the merits of this affair at the start. However, he is now disposed to accept the sincerity of the promoters of the company in their belief that they possess what they claim, this much being admitted without acknowledging actual merit to the project. If the promoters are disposed to be positively frank in their advertising, they might now come out with apology for their bald statement that they own mountains of fluorspar, that they have a belt of solid ore one-half mile wide and two miles long, and they might give full publicity to a letter written by Mr. Parker and accompanying the McClave report when he released it. In this letter he says: "Our conclusion is that the business hazards of this enterprise, which we have touched upon briefly in this report, are such that its commercial success is a problem still insufficiently demonstrated, and that upon the present evidence no such profits as are advertised can be expected." The writer is informed by the consulting engineer of the company that its metallurgist has perfected a process for the extraction of radium that will obviate troubles heretofore experienced in treating complex ores. He further says that the company owns extensive deposits of bauxite elsewhere, and is conducting research looking to a large consumption of its fluorspar in the commercial reduction of aluminum from the bauxite.

Troubles at the Colorado School of Mines cannot remain quiet for long. Little has been heard for some months regarding this once-famous school, although it is generally understood that affairs at Golden are in bad shape. A bill pending in the Legislature aims to compel governors of the State to see to it that at least three of the five trustees of the school are alumni, this measure being sufficient, it is presumed by the framer of the bill, to ensure the employment of capable honest presidents in the future. [The bill was killed, due to some clever lobbying.] Steps are being taken by the American Association of University Professors to conduct a thorough investigation of the many charges of disqualification preferred against the present executive.

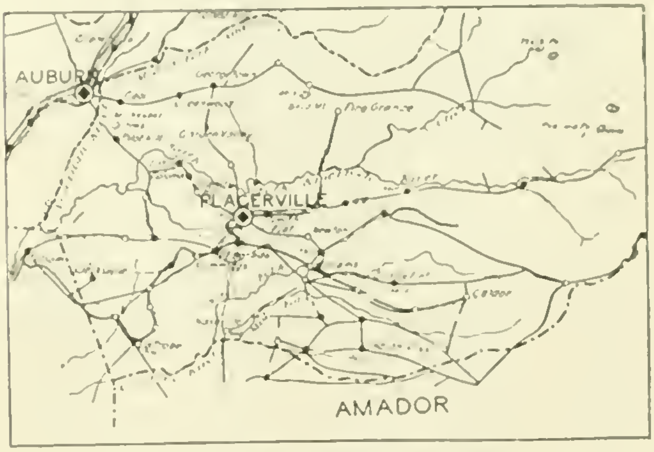
PLACERVILLE, CALIFORNIA

Mining in Eldorado County.

It is understood that the Manzanita gold mine, in the Kelsey district, 3½ miles north of Placerville, is developing so well that a company is to be incorporated to equip and operate it on a larger scale. At present a 10-ton daily capacity Bryant mill and a small concentrator are at work. A pay-shoot 700 ft. long and 20 ft. wide has been opened by a tunnel. The vein is incased in a well-defined diabase hanging and slate foot-wall. Five feet of the ore averages $9.17 per ton. Of this, $5.25 is saved on the plates and $3.92 in the concentrate. E. N. Fissler is general manager. C. M. Jackson and D. J. Mathews of Stockton are largely interested.

Six men are busy cleaning-up the Lotus mine, 9 miles north-west of Placerville, putting it in shape for a large mill. A lease and bond was given on the property by county supervisor J. B. Wagner to N. K. Cooper, of San Francisco, about a month ago. The mine is somewhat developed, and contains a well-defined, persistent, and payable vein.

W. E. Jones, of the Aluminum quartz mine, three miles south-east of Placerville, recently took advantage of the heavy rains to ground-sluice a 10-ft. square patch of surface placer ground on his property that was left by early-day miners. He recovered over $90. From another overlooked piece of ground containing two tons of gravel, he obtained $32; one nugget was worth $8. After this ground had been hydraulicked in the 'fifties, an old miner made an average of $3 daily for over six months with a rocker, washing the patches of bedrock that the giant operator missed.



MAP OF ELDORADO COUNTY, CALIFORNIA

Definite arrangements have been made to procure a new quartz mill and electric hoist at the Burger mine, situated on Coloma street, less than a mile north of the post office, within the city limits of Placerville. T. B. McLane is here from Seattle consulting with his partners A. L. Conger of Berkeley, and N. H. Burger of this town. Two long pay-shoots have been opened in the 5-ft. vein, samples of which give assay of $27 gold per ton.

The recent rain has supplied an abundance of water so that the barrel gravel mill at the Rising Hope deep-gravel mine, three miles east, is now in constant operation washing the large body of cemented deep-channel gravel that was found there last fall. On March 4 the manager brought in about 100 oz., the result of a part clean-up. Charles M. Henson is mine superintendent and George O. Perry is millman.

F. L. Kendall, of Denver, arrived here on March 1. He represents a Colorado company and is examining the Bean Hill gold and platinum placer mine, 12 miles south-east of Placerville. This is the property from which several large pieces of platinum were reported to have been recovered.

THE MINING SUMMARY

ALASKA

Juneau.—Alaska Gastineau Mining Co. has issued its report for the last quarter of 1918. Results, compared with previous periods, are as under:

	Fourth	Third	Second	First
Tons	287,571	218,930	309,249	469,695
Value per ton	$0.986	$1.323	$1.164	$0.986
Extraction, per cent.	80.22	82.39	81.96	79.92
Extracted	0.791	1.093	0.954	0.790
Cost per ton	1.060	1.140	0.990	0.800
Loss per ton	0.270	0.050	0.040	0.080

The mine contains 1,718,173 tons of ore broken in stopes, according to the survey at the end of 1917. A re-survey is now being made. No development was done. The year shows an operating loss of $110,290.

The company's gold output in February was 162,400 tons of 83.7c. ore, of which 77.3% was recovered.

ARIZONA

Ajo.—The Ajo-Cornelia Copper Co.'s property, against which the E. J. Longyear Company obtained an injunction for $2000 for diamond-drill work, has been advertised for sale. Shareholders have appealed to the State Corporation Commission for protection, claiming mismanagement by its officers. As soon as the tangle is adjusted shareholders are prepared to pay the debt.

Bisbee.—Calumet & Arizona is to pay $1 per share, equal to $642,462.

Indefinite suspension of operations at the Denn-Arizona has been necessary because of fire. Two hundred men have been laid off.

Globe.—The Arizona Commercial Mining Co. is suing the Iron Cap Copper Co. for alleged illegal extraction of ore, also for refusing to share the expense in draining the ground within its boundary. The Iron Cap property is between two areas of the Commercial. The latter alleges that in the last six years it has spent over $250,000 in draining its ground, which also drained that of the Iron Cap, and claims damages at $150,000 for this work. Regarding the ore mined, the Commercial claims that over 250,000 tons, for which the Iron Cap received $3,000,000, was taken out. The hearing on these actions was to be held at Boston on March 11.

Grand Canyon.—Developments have been so satisfactory in the past eight months at the vanadium property of W. I. Johnson on Cataract creek that a 25-ton mill is to be erected immediately.

Jerome.—It is announced that following the shut-down due to the recent strike here the Green Monster Mining Co. will not resume operations until industrial conditions are more stable.

Ray.—The Ray Consolidated Copper Co. pays 50 cents per share on March 31, equal to $788,589. This is a reduction of 25 cents.

ARKANSAS

Yellville.—The dry concentrating plant for zinc ore erected here some time ago by the Sutton, Steele & Steele company is to be re-started. The process is said to be successful, especially in districts where water is scarce.

CALIFORNIA

Bakersfield.—Delegates from the 14 Oil, Gas and Refinery Workers' locals of California, on the 6th and 7th discussed the wage award made public by the Federal Oil Inspection Board at Los Angeles. Lee Scott, vice-president of the International Oil, Gas and Refinery Workers' Association presided. The Oil Inspection Board announced a wage-scale that the oil-workers are said to consider too low. The demand of the oil-workers submitted last September to the Board was for a $5 per day minimum. The award, individual members of the union say, amounts in effect to about 25 cents per day increase for single men and 50 cents for married men. The majority of the 15,000 members of the California branch of the Oil Workers' Union are said to come under the 25-cent increase or those who earn now from $4 to $4.25. The present minimum wage is $4 for eight hours.

The wage-schedule was accepted, excepting the $4 minimum and 9-hour day for teamsters and truck-drivers. If within 30 days there is no adjustment to the $5 minimum and the 9-hour day, there will be an appeal to the Secretary of Labor.

The oilmen have locals at Bakersfield, Taft, McKittrick, Maricopa, Lost Hills, Los Angeles, Coalinga, Richmond, Rodeo, Brea, Whittier, Santa Maria, Martinez, and El Segundo.

The Standard Oil Co. of California in 1918 produced 22,446,021 bbl., a gain of 23% over the 1917 yield. Stocks at the end of last year were 11,825,598 bbl., a decrease of 19%. The value of sales increased 29%. The earnings were $44,276,582, after deducting operations and marketing. After writing off $3,895,758 for depreciation, $6,022,228 for depletion, and $19,405,462 for excess profits tax, the net profit was $14,953,074. In 1917 the profit was $18,649,630. Dividends in 1918 were $12,421,663, against $9,316,248. Total assets are $145,231,331, an increase of $18,308,171.

Heroult.—The Noble Electric Steel Co.'s smelter has been closed, the company being in financial difficulties.

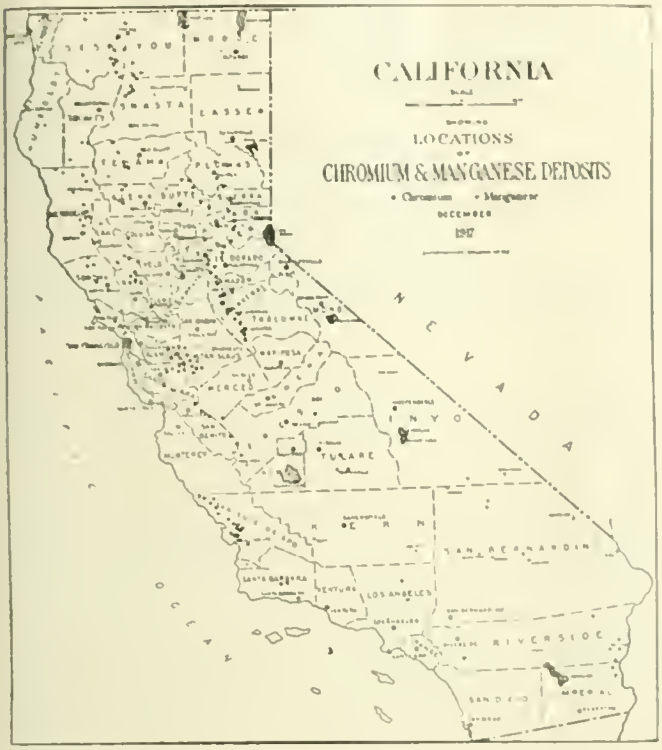
Keswick.—The Mountain Copper Co. has stopped work at its Iron Mountain mine near this place, also its New Year mine near Coram. The Hornet mine, a mile away, is to be kept open.

Plymouth.—On March 7, the California Exploration Co., controlling the Plymouth Consolidated, paid a dividend of 12 cents per share, equal to $28,000.

San Francisco.—The value of gold, oil, and all other minerals in this State is shown in the following table, prepared by the State Mining Bureau:

Year	Gold	Oil	All minerals
1890	$12,309,793	$384,200	$18,039,666
1900	15,863,355	4,152,928	32,622,945
1910	19,715,440	37,689,542	88,419,079
1915	22,442,296	43,503,837	96,663,369
1916	21,410,741	57,421,334	127,901,610
1917	20,087,504	86,976,209	161,202,962
1918	17,250,000	123,000,000	191,100,000

The Bureau has issued Bulletin 76, 'Manganese and Chromium in California', by W. W. Bradley, Emile Huguenin, C. A. Logan, W. B. Tucker, and C. A. Waring (since deceased). The publication covers 248 pages, is well illustrated with photos and maps, and contains descriptions of every property in the State, and names of buyers of the ores. The accompanying map is abstracted therefrom. Those interested should procure copies. The price of the bulletin is 50 cents.



The State Mining Bureau announces that Bulletin 78, 'Quicksilver Resources of California,' by W. W. Bradley, is now ready for distribution. The price is $1.50. This work was reviewed fully in the 'Press' of January 4, 1919.

Sutter Creek.—The Old Eureka company has finished sinking to 3150 feet.

COLORADO

Alma.—The Louisiana-Colorado Mining Co. in Park county has just finished its 200-ton mill. The flow-sheet is simple, including a ball-mill, Dorr classifier, and flotation plant, the tailing from which pass over a Deister-Overstrom and a rectangular deck-table.

Boulder.—The Colorado Pitchblende Co. is erecting machinery at its fluorspar mine at Jimtown. A contract has been let for hauling concentrate to Boulder.

Breckenridge.—Owing to the mild winter and light snowfall, dredging will be started this season about a month earlier than usual. There are five boats now being overhauled.

Central City.—Lessees at the Becky Sharpe mine in Russell gulch have opened some pockets of rich gold-silver-lead-copper ore. These shoots are 6 to 12 in. wide, but the whole formation is 36 to 60 in. Two cars, 52 tons, of second-class ore sent to the Argo mill at Idaho Springs averaged 4 oz. gold, 8 oz. silver, and 2.85% copper. The ore is easily mined.

IDAHO

Wallace.—As the result of a recent meeting of the principal mine operators of the Coeur d'Alene region, an early announcement of a reduction in wages is expected. A committee was selected to look into the cost of living, and see that all merchants are keeping prices at a minimum. This action is similar to that recently taken at Butte, where operators threatened to open their own stores unless merchants reduced prices. Even if a sharp reduction in wages should be made, no labor trouble is anticipated, as most of the men are said to realize the necessity for such action owing to the present lead market. The radical element in the Coeur d'Alene is greatly in the minority.

The Consolidated Interstate-Callahan mine is to be closed on account of the lead and spelter markets. Fully 300 men will be dismissed.

The Hecla company pays 15c. per share, equal to $150,000, on March 28. This makes $7,405,000 to date.

MICHIGAN

Houghton.—Dividends payable on March 31 are: Allouez, $1, equal to $100,000; Isle Royale, 50 cents, equal to $75,000; and Quincy, $1, equal to $110,000.

Wolverine pays 50 cents per share, equal to $30,000, on April 1. This is a reduction of 50 cents from the previous quarter. The total for 1919 is $1.50 per share.

The Victoria Copper Mining Co. in 1918 made a net profit of $17,046. The surplus—cash, bonds, and copper—totals $238,228. From 106,730 tons of ore the yield was 1,533,536 lb., of which 1,230,230 lb. was sold. The ore averaged 0.72% copper. The cost was 22.2 cents per lb. Development covered 2847 ft. There are over 14 miles of workings in the whole property. Results generally may be termed fairly satisfactory. George Hooper is superintendent.

The 15% cut in wages by the C. & H. is general throughout the Copper Country, affecting 18,000 men.

Copper continues to accumulate at every smelter in the district, and there is more unsold metal on hand here now than at any time within four years. Smelters continue their output without regard to market conditions.

MISSOURI

Joplin.—Production of the Tri-State region last week was as under:

State	Blende, tons	Calamine, tons	Lead, tons	Value
Kansas	1327	...	347	$78,922
Missouri	1428	788	160	92,950
Oklahoma	6348	...	911	330,357
Average value.	$42*	$28†	$62‡	

*60% Zn. †40% Zn. ‡80% Pb.

The total value is $75,000 more than the previous week. The demand was much better last week.

MONTANA

Butte.—East Butte Copper Co. has blown-in its smelter and notified custom producers to that effect.

North Butte Mining Co. has curtailed its ore output from 1200 to 450 tons daily.

Thompson Falls.—The Silver King Mining Co. has been incorporated by Kellogg, Idaho, men, to operate the Silver King mine, near this place. The property was acquired some time ago by Mr. Price and associates, and development has been under way. The mine has a record of nearly $100,000 in shipments of ore carrying high value in silver.

NEVADA

Dayton.—The Dayton Placer Recovery Co., a Utah corporation, has filed a petition in voluntary bankruptcy. Assets total $34,214, and liabilities $48,760. Of the latter, $3314 is due for wages. The cyanide plant was treating gold-silver-mercury tailing from the old Comstock mills.

Ely.—The Boston Ely Mining Co., Smokey Development Co., and Ely Northern Copper Co. have been consolidated by S. H. Williams into the Boston Ely Consolidated Mining Co. The capital is $1,000,000, shares $1 par. About 250,000 shares will be held in the treasury. Cash amounts to $150,000. There are no debts, bonds, or notes. L. E. Whicher of New York has had the properties examined. The Ely Northern is said to have a fine deposit of carbonate ore. Work is to start in the Smokey, on a sulphide vein found in the long cross-cut tunnel.

Nevada Consolidated has reduced operations to 50% of capacity. The mill works five days per week. The smelter is catching up on the accumulation of ore and concentrate.

Nevada Consolidated Copper Co. pays 37½ cents per share, or $749,796, on March 31. This is a reduction of 37½ cents.

Goodsprings.—The Yellow Pine company is storing its zinc concentrate but is shipping lead. The mill is to be altered, and a calcining-plant erected.

Jarbidge.—This centre apparently has a good future. The Elkoro Mines Co., E. A. Austin general manager, started its 200-ton mill on March 1, 1918, and it has continued running ever since. Rolls are used for grinding when the pulp goes to the cyanide plant. A $30 average is said to be maintained. This company owns the Longhike claims, including the Log Cabin, Laurel, O K, and Starlight groups, also a controlling interest in the Jarbidge gold and the North Star claims and several others. The ore being treated is from the Longhike mine.

The owners of the Bluster mine and mill have completed plans, and will erect a cyanide plant as soon as weather conditions permit.

The Jarbidge Nevada Mining Co., of Tacoma, owner of the Legitimate mine, is having 300 lb. of its ore tested at Salt Lake City, with the idea of erecting a flotation plant. The saving by flotation is not as good as that made by cyanidation when treating Jarbidge ores. This may be due to the colloidal nature of the ore.

Tonopah.—On April 1 the Tonopah Extension pays a dividend of 5%, equal to $64,140. This makes $1,980,000 to date.

The Jim Butler company is to resume development in the Desert Queen mine.

The Tonopah Belmont pays a dividend of 10%, equal to $150,000, on April 1. This makes $9,718,063 to date.

Four new companies, making fifteen in all, are operating in the Divide district, namely, the Silver King Divide, Alto Divide Mining, North Divide, and Gold Wedge Divide. All are said to be favorably located and are managed by reliable men.

A brief summary of what is being done in the Divide district is as follows:

The Allied Divide has been organized to develop claims adjoining the East Divide.——The Alto Divide, next to the Allied and East, is sinking. A 1000-ft. electric hoist and 7-drill compressor have been secured.——The Brougher Divide is exploring on the 500-ft. level, and has cut some ore. G. Hanson is in charge.——The Divide Consolidated is sinking. A geologic report has been made by A. H. Elftman.——The Divide Extension is sinking from 150 to 300 ft. Machinery has been purchased from Manhattan. E. Bevis is superintendent.——The East Divide is sinking through favorable ground at 300 ft. depth.——The Gold Wedge is prospecting from a 70-ft. shaft, and is preparing for a head-frame and hoist.——The North Divide is erecting machinery.——The Rosetta is sinking to 100 ft.——The Silver King has started sinking, and has secured machinery at Manhattan.——The Tonopah Divide shaft has reached a depth of 520 ft. The south cross-cut at 475 ft. is out 100 ft. in rhyolite-breccia, similar to that in the levels above, where the rich ore is being mined. At 370 ft., the vein has been opened 350 ft. beyond the south cross-cut, still in ore. Daily shipments to the MacNamara mill at Tonopah are 35 tons. William Watters is superintendent.

The Tonopah Divide sent 245 tons of ore to be milled last week.

Unionville.—The West End Consolidated of Tonopah has purchased the Adamson claims, near the Arizona mine. The ore, which is in rhyolite, carries good value in silver and gold.

NEW MEXICO

Magdalena.—The Graphic, Kelly, and Ozark zinc mines are not doing much work at present. At the Kelly there are 40 or 50 lessees.

Santa Rita.—Chino Copper Co. pays 75 cents per share on March 31, amounting to $652,485. The previous dividend was $1.

OKLAHOMA

Picher.—An oil-flotation machine is to be tried here by the R. W. Johnson Association on local zinc ore.

SOUTH DAKOTA

Lead.—The Homestake Mining Co. distributes 50c. per share, $125,580, on March 25. The total to date is $41,794,444.

UTAH

Bingham.—The Bingham Mines company is to pay 25 cents per share, equal to $37,500.

Utah Copper Co. pays $1.50 per share, equal to $2,436,735, on March 31. This is a decrease of $1.

Eureka.—Rich silver-lead ore is being mined from the bottom—1875 ft.—level of the Eagle & Blue Bell mine. The shoot is continuous from 1700 ft. Exploration is under way at 2000 ft. A dividend of 5 cents per share, equal to $44,657, has been declared.

The Tintic Standard company has arranged for construction of an 11-mile spur track to the mine, connecting with the D. & R. G. This line will also aid the Iron King, Eureka Lily, Eureka Bullion, Provo, and other properties. The new hoist at the Standard is finished.

Park City.—The Silver King Consolidated is holding its lead-zinc concentrate until the market improves or costs drop, or both, to ensure a reasonable profit. The company is offering $200,000 in short-term notes to enable this product to be carried and development continued.

The Ontario Silver Mining Co. during 1918 had a total revenue of $605,859, of which $561,768 was from ore. Cash assets total $554,674. Little profit was made during the past six months owing to abnormal conditions.

WASHINGTON

Chewelah.—The United Copper company is opening 14 in. of 600-oz. silver ore on and below the 1300-ft. level. The remainder of the ore assays 5% copper and 20 oz. silver per ton. Two carloads in February were settled for $3500 each. An electric hoist of 1000-ft. capacity has been ordered.

A chamber of mines is being organized here to look after mining in Stevens county.

Leadpoint.—The Lead Trust company is erecting a 60-hp. boiler, 25-hp. engine, compressor, etc., and is to advance its No. 2 tunnel. The sulphide ore carries lead and silver.

Northport.—The Northport S. & R. Co.'s plant was closed on February 25, for how long, nobody knows. Work has been started on the drossing plant to cost $150,000.

Tacoma.—The A. S. & R. smelter here has only one furnace in blast, compared with three last year. Wages were cut 12½% on March 1, the minimum now being $3.75 per day. A number of mines in British Columbia and others contiguous to the smelter feel the reduction in payment for copper ore.

CANADA

British Columbia

Anyox.—Granby Consolidated, from March 1, is paying wages on a sliding-scale, regulated by the price of copper.

Fire last week damaged the roof of the blast-furnace and converter building.

Britannia.—The Howe Sound company has discharged over 400 men, due to the copper market.

Ontario

Boston Creek.—A depressed diamond-drill hole at the Cotter property, about 720 ft. long, has cut 28 ft. of ore at a depth of 492 ft. The average assay is $12.42 per ton.

Cobalt.—The ore-sampling firm of Campbell & Deyell, here since 1909, has discontinued business. Ore containing 61,000,000 oz. passed through the plant, and metallics weighing 1,200,000 oz. were melted there.

The Trethewey Silver-Cobalt Mines company in 1918 made a net profit of $103,368. The mill treated 24,514 tons at a cost of $2.21 per ton. Silver in ore-reserves is estimated as 159,172 oz., a decrease of 39%. An interest has been acquired in the Castle mine at Gowganda, where conditions are encouraging.

Porcupine.—The Hollinger last week started another 40 stamps crushing. A 1000-hp. hoist and 9000-cu. ft. compressor are to be added to the equipment. The Hollinger pays a dividend of 5 cents per share on February 25, equal to $246,000.

The Porcupine-Crown Mines company made a profit of $4814 last year, against $109,421 in 1917. Operations were only conducted in the first half of the year. The mill treated 10,907 tons of $9.64 ore, extracting 97.09%. The surplus is $271,956. The main vein has been opened to a depth of 1100 ft., reserves being valued at $500,000. A continuation to 1400 ft. is expected. A cave-in carried down three levels, but this will soon be cleared away and mining will be resumed at an early date.

The University of Illinois maintains 14 research graduate assistantships in the Engineering Experiment Station. Two other such positions have been established under the patronage of the Illinois Gas Association. These, for each of which there is an annual stipend of $500 and freedom from all fees, except the matriculation and diploma fees, are open to graduates of approved American and foreign universities and technical schools who are prepared to undertake graduate study in engineering, physics, or applied chemistry.

The Spokane Engineering and Technical Association, composed of nine societies having chapter headquarters at Spokane, held a two-day session last week. L. K. Armstrong was chairman. The membership embraces men actively engaged in eastern Washington, northern Idaho, western Oregon, western Montana, and southern British Columbia. The societies represented are civil, mining, electrical, mechanical, chemical, and electro-chemical engineers, architects, and the society for the promotion of engineering education.

The Colorado Chapter of the American Institute of Mining Engineers enjoyed a splendid dinner, February 8, at the Denver Athletic Club. The affair was enlivened by several surprising cabaret numbers. The following officers were elected for the current year: Robert J. Grant, chairman; W. H. Leonard, vice-chairman; Robert M. Keeney, secretary-treasurer; these, with Stephan Ionides and Robert Hursh, executive committee. Lieut. Horace Wells of Denver informally adressed the gathering upon his part in war aviation, especially his experience as a German prisoner of war. ——At the February meeting of the Denver Teknik Club, Harry J. Wolf spoke at length upon recent research in the treatment of manganiferous-silver ores.——The Colorado Scientific Society held a dinner, February 15, at the Shirley hotel, and was addressed by Stephan Ionides upon H_2SO_4 and M. E. K., this cryptic title covering late developments in the manufacture of war munitions.

PERSONAL

Note. The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Scott Turner is at Toronto.

W. P. Hammon has returned from Boston

J. C. Hopper has returned to San Francisco from Silverton, Colorado.

W. H. Woodbury, secretary of the Duluth Engineers Club, was in San Francisco last week.

W. H. Goodchild, who has been to Cuba, has returned to New York on his way to London.

R. T. Schraubstadter, of St. Louis, has been examining a mine in Plumas county, California.

D'Arcy Weatherbe sailed from New York to London on March 15, on his return from China.

W. H. Weed was at Tonopah last week, as advisor to the Divide Consolidated Mining Company.

S. M. Levy, superintendent for the Calaveras Copper Co., has returned to Copperopolis, California.

George R. Allen, president of the Chosen Minerals Co., has arrived in San Francisco from Keijyo, Korea.

S. A. Knowles succeeds **James Humes** as superintendent for the Silver King Coalition, Park City, Utah.

G. H. Edmonds, superintendent of the Conrey dredges in Montana, has been in San Francisco to consult with **Hennen Jennings**.

Among those decorated by the Belgian government are two mining engineers: **Edgar Rickard** and **E. Coppee Thurston**.

Morton Webber has arrived here from New York. He has become consulting engineer to the Empire Copper Co., at Mackay, Idaho.

H. C. Dudley has received his discharge as Captain of the 36th Engineers of the Army, and is now in the Landsdale building, at Duluth, Minnesota.

C. M. Wilson, until recently engineer for the Garfield Smelting Co., has been appointed chief engineer for the A. S. & R. Co., at El Paso, Texas.

H. C. Hoover is withdrawing from his work as international Food Administrator in July, and will resume his practice and business of mining engineering, with offices at New York.

Lloyd C. White, designer and superintendent of the Mountain Copper mill, has joined the firm of Burch, Caetani & Hershey, on the resignation of **Gelasio Caetani**, who finds it necessary to remain in Italy to look after the property of his family, the head of which is the Duke of Sermoneta.

THE POSITION OF ASSOCIATE EDITOR ON THIS PAPER IS VACANT. APPLICATIONS FOR THE APPOINTMENT ARE INVITED.

Obituary

J. K. Batchelder, superintendent of refineries for the Consolidated M. & S. Co. of Canada, at Trail, B. C., died recently of pneumonia. He was born at Wilton, New Hampshire, in 1890.

James W. Abbott died in February at a sanatarium near Clifton Springs, New York. He had been an invalid for several years. A graduate of the Sheffield Scientific School of Yale University, he took a prominent part in the early mining of the San Juan region in Colorado, living successively at Lake City and at Ouray. He was a public-spirited man and did much to foster the 'good roads' movement, writing many articles on the subject and participating in conventions organized for the purpose.

THE METAL MARKET

METAL PRICES

San Francisco, March 11

Aluminum-dust, large and small lots, cents per lb	65—70
Antimony, cents per pound	8.00
Copper, electrolytic, cents per pound, in carload lots	15.75
Lead, pig, cents per pound	5.50— 6.50
Platinum, per ounce	$100
Quicksilver, per flask of 75 lb	$75
Spelter, cents per pound	8.00
Zinc-dust, cents per pound	15 00

Tungsten in Colorado has been quoted at $12 to $15 per unit of 60% concentrate.

EASTERN METAL MARKET

(By wire from New York)

March 11.—Copper is quiet but firmer. Lead is dull though steady. Spelter is stagnant and easy.

SILVER

Below are given official (not Government) quotations, in cents per ounce, of silver 990 fine. In order to make prompt settlements with smelters and brokers, producers allow a discount from the maximum fixed price of $1 01½, hence the lower price. The Government has not fixed the general market price at $1, but will pay this price(as from April 23, 1918) for all silver purchased by it. The equivalent of dollar silver (1000 fine) in British currency is 46 65 pence per ounce (925 fine), calculated at the current rate of exchange On August 15, 1918, the Treasury announced that the maximum price was fixed at $1.01½ per ounce. The British government fixed its maximum at 49½ pence, on September 2, but on November 12 this was changed to 48¾, on December 13 to 48 7/16, and in February to 47¾ pence.

The Lead Producers' Committee for War Service, A. K. Mitchell, secretary at New York, has issued a 27-page pamphlet covering its activities in 1917 and 1918. This organization aided the Government in direct purchases of lead and distribution of the supply. The Committee consisted of C. H. Crane of the St. Joseph Lead Co., F. W. Bradley of the Bunker Hill & Sullivan, Edward Brush of the A. S. & R. Co., E. J. Cornish of the National Lead Co., F. Y. Robertson of the U. S. S. R. & M. Co., H. L. Day of the Pennsylvania Smelting Co., and I. H. Cornell of the St. Joseph Lead Co. Allocation of lead, prices, and production are covered in this review.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Date					
Feb.	11	95 00	Feb.	25	85.00
"	18	90.00	Mch.	4	85.00
			"	11	75.00

June	85 50	112 00	....	Dec.	117.42	115.00	....

The quicksilver market is active at the present price. If it goes lower some mines will have to suspend operations, as evidence given before the Federal Tariff Commission here last June showed that costs are from $60 to $75 per flask.

TIN

Prices in New York, in cents per pound. The monthly averages in 1918 are nominal. On December 3 the War Industries Board fixed the price to consumers and jobbers at 72½c. f.o.b. Chicago and Eastern points, and 71¼c on the Pacific Coast. This will continue until the U. S. Steel Products Co.'s stock is consumed.

Eastern Metal Market

New York, March 5.

There is a tendency for most of the markets to be firm, although prices of some metals have declined further.

Antimony is unchanged.

Copper has reached lower levels, but on small transactions.

Lead is more active in both inquiry and sales, and prices are firm.

Tin has no market, it being still under restrictions that are unnatural and demoralizing.

Zinc is inactive and dead, with prices nominal but fairly steady.

ALUMINUM

No. 1 virgin metal is quoted at 31 to 32c. per lb., New York, for early delivery, but demand is light. An announcement by the War Trade Board is to the effect that the importation of aluminum ingots into the United Kingdom is not prohibited, but that aluminum sheets require an import license.

ANTIMONY

The market is dull with quotations nominal at 7 to 7.12½c. per lb., duty paid, New York, for wholesale lots for early delivery.

COPPER

The market has continued to decline until yesterday electrolytic had sold as low as 15c. per lb., New York, for early delivery. It was stated that this had been or could be shaded, but actual transactions below 15c. have not been confirmed. We therefore quote the market at 15c., New York, for electrolytic, with Lake nominal at about 15.75 to 16c. per lb. Demand, even at these low prices, which are generally admitted as under cost, is very small, and the foregoing quotations are based on small sales in all cases. Large producers generally are meeting the 15c. price, but no lower. The feeling is becoming more evident that bottom has nearly been reached. Export demand is insignificant. An interesting fact in this connection is that on a recent export inquiry it was impossible to obtain quotations from the leading members of the Copper Export Association. A tentative agreement has been made between about 90% of the American producers and a representative of the Ordnance Department whereby the 140,000,000 lb. of copper bought by the Government at 26c. per lb. late in the War will be marketed by producers during the next 15 months, probably at the market price. Reports are conflicting as to whether a minimum price was decided upon. Casting copper is quoted at 14.75c. per lb., New York.

IRON AND STEEL

The need of the steel market is stabilized prices, according to the general feeling of leading steel-makers. There have been such prices for three months now, and producers count on being able to maintain them without Government intervention. Any cut, even a sharp one, which would leave the impression of further recessions in the near future, would not help business now. The February pig-iron output, according to 'The Iron Age,' was 2,940,168 tons, or 105,000 tons per day, which is 1519 tons less than the daily output in January. On March 1 there were 306 furnaces in blast, against 323 on February 1. Better furnace operation, due probably to better coke, is reported.

LEAD

Considerable activity has developed in the lead market, and a fair business has been done in the last week. The market is firm at 5.25 to 5.35c., New York, or 5 to 5.10c., St. Louis, the former prices being those of the leading interest (A. S. & R. Co.), which has probably taken most of the business. All sales in the outside market have been close to 5.35c., New York. All consuming lines have participated in this demand, this being cited to demonstrate the fact that consumers have about realized that the market has reached bottom. Sentiment is approaching the bullish stage, as production has been curtailed decidedly and the labor situation is not helping matters as to output or an accumulation of stocks.

TIN

There is little to be said about this market, which from day to day and from week to week is virtually held by the throat. Dissatisfaction is growing. Restrictions are still in force, the only metal available in wholesale quantities being the allocated metal which is held at 72.50c., New York, a fixed price. In this letter some weeks ago it was reported that it was rumored that further restrictions would be placed on the tin market, or in other words, that the lid would be placed on the sales of all tin, even by jobbers, with the exception of course of the allocated metal. It is now intimated that this plan has been modified, in that the price of American tin will be marked up, ostensibly to lessen the competition with the allocated metal. The originators of this controlled market are surely having a most difficult and sad time. The market is dead, for there is none. Spot Straits is nominal at 72.50c., New York, while American 99% metal can be bought at 67 to 68c. per lb., New York. The only free movement, devoid of restrictions, is in lots of 5 tons and less. Tin arrivals in February were 2450 tons, 2340 tons coming through Pacific ports. The total to March 4, 1919, has been 4366 tons, against 7740 tons to March 1, 1918.

ZINC

Consumers are neither inquiring nor buying, and the market is at a standstill. It is believed that stocks are increasing rather than otherwise, no more. Government reports of stocks and output are not being published, and this is a disappointment to many. The quotation for prime Western is nominal at 6.25c., St. Louis, or 6.60c., New York, for early delivery or even most any delivery. The entire situation is one of marking time.

ORES

Ferro-chrome. Alloy containing 60 to 70% chromium is nominal at 32c. per lb. of contained metal, with light demand.

Manganese. High-grade Indian manganese ore has been offered at seaboard for 80c. per unit, but no sales have been effected, it is said.

Manganese-Iron Alloys.—Producers are generally quoting $200 per ton delivered for 78 to 82% ferro, with $3 deducted for each unit under 78%. Small trading among consumers has been at $150 per ton, delivered. Spiegel is nominal at $50 to $53, delivered. Re-sale 18 to 22% alloy has been offered at $42.50 per ton, point of shipment.

Molybdenum. The market is quiet and nominal at 85c. per lb. of MoS_2 in high-grade concentrate.

Tungsten. There have been no developments and no trading. The market is flat with practically no quotations. It is probable that ferro can be bought under $1.50 per lb. of contained tungsten. If so, this would mean about $14 to $15 per unit for high-grade concentrate.

Company Reports

UNITED VERDE EXTENSION MINING CO.

Property: mine, smelter, and railway at Jerome, Arizona.

Operating Officials: G. Kingdon, general manager; Barry Hogarty, superintendent of smelter.

Financial Statement: the gross revenue in 1918 was $15,156,716. Operations cost $5,596,485, State and County expenses, $661,244, estimated Federal taxes, $2,000,000, and depletion and depreciation, $3,567,933, leaving $3,331,054 net. After paying dividends the surplus was $1,756,054. Supplies are valued at $740,907; cash, $1,874,646; Liberty Bonds, $3,350,000; due for ore and bullion sold, $852,445; and ore and bullion on hand, $3,477,407.

Dividends: No. 9 and 10 absorbed $1,575,000, making $7,455,000 to date.

Development: underground work totaled 10,919 ft., including 7155 ft. in the haulage-tunnel. No prospecting was done and no new orebody was developed. When the Audrey shaft is finished in April 1919, driving will be started at 1500, 1600, and 1700 ft. depth. It will be necessary to drive 900 ft. to get under the ore. New systems of mining, ventilation, and safety will result in lower costs. Only 1180 ft. remained to be driven in the haulage-level to connect the Texas shaft and the section east of the Audrey. This level will mean no change of ore-cars from mine to works and the disuse of the aerial tram.

Production: the new smelter was blown-in during July, and is a complete success. The company's output (some custom work was done) is shown in the following table:

	Tons	Copper, lb.	Gold, oz.	Silver, oz.
Ore to custom smelters......	62,277	32,261,742	615	224,325
Ore to U. V. X. smelter.....	71,258	23,229,335	2431	279,414
Total	133,535	55,491,077	3046	503,739
Average per ton....................		407 lb. (20.35%)	0 024	4.18

PORTLAND GOLD MINING CO.

Property: mines and mills at Cripple Creek, Colorado.

Operating Officials: G. M. Taylor, general manager; Fred Jones, superintendent at the mine; T. B. Crowe, superintendent at the mill; Luther Lennox, assistant; and Merrill Metallurgical Co., consulting metallurgists.

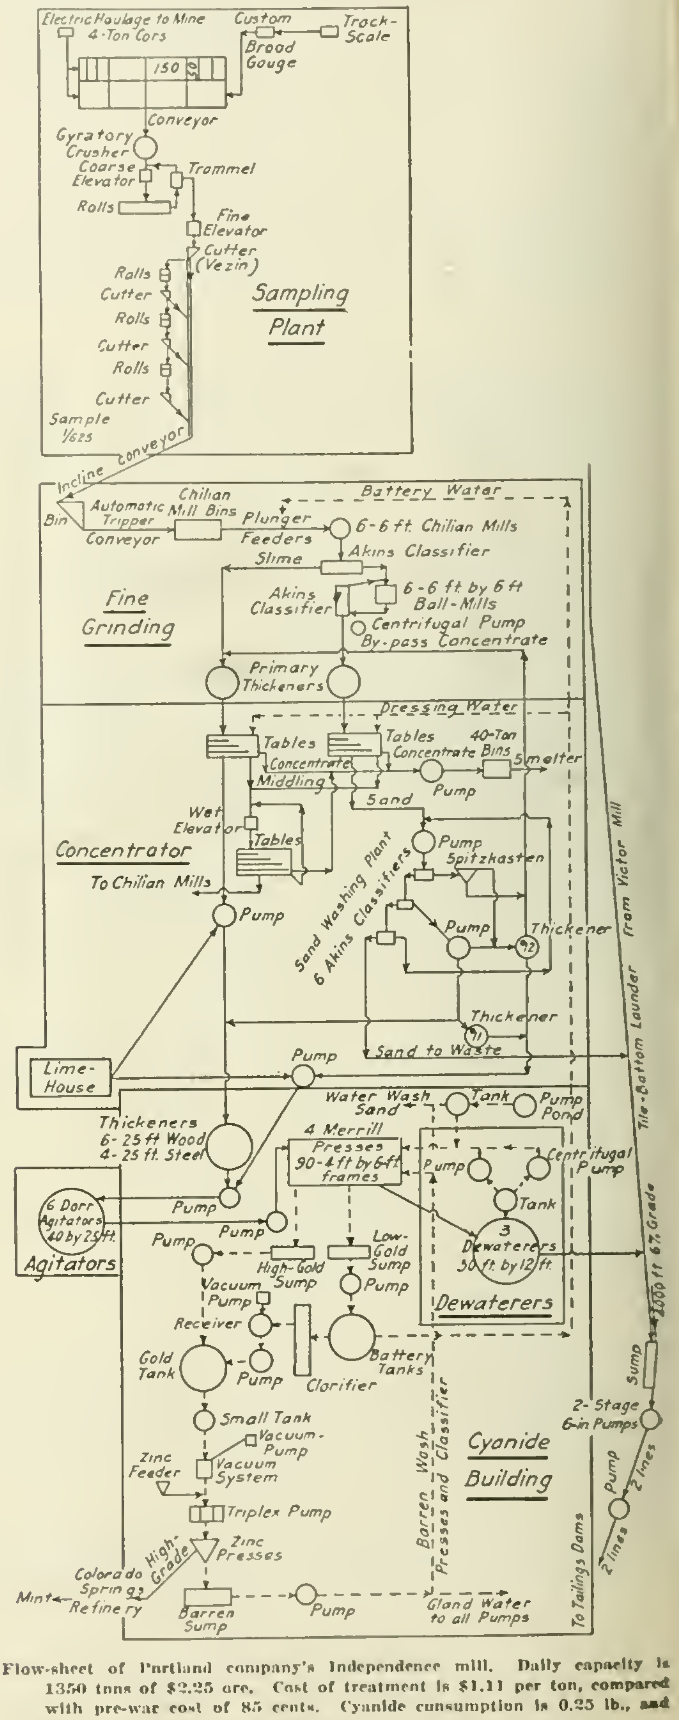
Financial Statement: the net profit in 1918 was $196,596. The balance from 1917 was $278,383, and that carried to 1919 was $127,622. Current assets total $395,966, and liabilities $14,052.

Dividends: the total last year was $300,000, making $11,257,080 to date.

Development: there was accomplished 8071 ft., making 63 miles in the Portland mine. The Independence mine has 17 miles of openings. The branch tunnel from the Roosevelt drainage-tunnel to No. 2 shaft of the Portland, at a depth of 2131 ft., was connected during the year. At the end of 1918 the main shaft was sunk to No. 21, or the drainage-level. Development of No. 1 vein will soon be under way. The Lee No. 5 orebody was cut by the tunnel cross-cut, and driving is opening high-grade ore. Generally the outlook is promising.

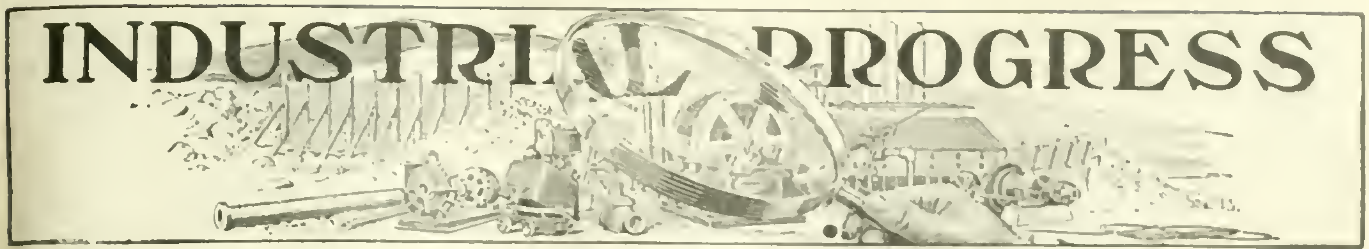
Production: the Colorado Springs mill was closed on March 31, and the Victor mill on July 30, leaving the Independence in operation. The extraction at the last named was good, but the profit was small. Almost without exception, every improvement devised to reduce costs was immediately offset by some increase in cost of labor or supply entering into the extraction of gold. The output was 53,887 tons (Colorado Springs) valued at $1,120,851, and 522,756 tons (Victor mills) worth $1,071,925. The output to date is 3,949,248 tons, worth $48,773,378 gross.

Experiments were made on the tailing at Colorado Springs in an endeavor to devise a process for extracting potash therefrom. This material contains 7% K_2O, and there is about 2,000,000 tons of it awaiting treatment. The Denver letter in the Review of Mining in this issue discusses the potash possibilities of two large dumps at Colorado Springs.



Flow-sheet of Portland company's Independence mill. Daily capacity is 1350 tons of $2.25 ore. Cost of treatment is $1.11 per ton, compared with pre-war cost of 85 cents. Cyanide consumption is 0.25 lb., and zinc consumption 0.19 lb. per ton of ore.

INDUSTRIAL PROGRESS



INFORMATION FURNISHED BY MANUFACTURERS

PULVERIZING AND BLOWING MACHINERY FOR POWDERED COAL

By F. B. Collin

*Electric power is probably used more extensively in the preparation and handling of pulverized fuel, on the basis of kilowatt-hours per ton, than is the case with any other form of fuel. One possible exception is briquetted fuel. In this country, however, the amount of fuel briquetted is small [477,235 tons in 1918]. Electric power is used for the following operations in connection with pulverized fuel: Crushing the coal to 1-inch size or less; energizing magnetic separators; rotating the dryer-drums; pulverizing the coal; elevating lump and pulverized coal; driving screw-conveyors; driving feed-screws for burners; driving reciprocating air-compressors for high-pressure air, transport systems, and blast-feed to burners; driving centrifugal air-compressors for supplying air for combustion at a pressure of 1 lb. per square inch; and driving low-pressure blowers for supplying air for combustion at lower pressures, and for conveying coal in suspension through pipes; also for separating the finished product from the unfinished in pulverizing.

These pulverizers are a type commonly used for pulverizing coal

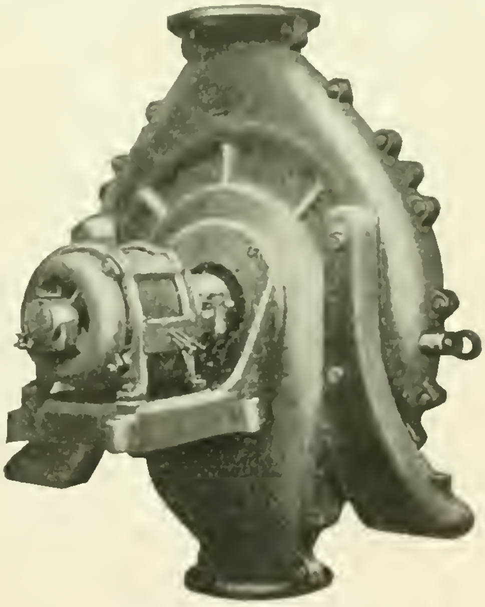
No one plant uses power for all of these items, as the list includes the component parts of several different systems for preparing and handling pulverized coal.

The amount of pulverized fuel used in the United States at mid-1918 was 10,000,000 tons, divided by industries approximately as follows: manufacture of cement, 6,000,000 tons; iron and steel industry, 2,000,000 tons; production of copper, 1,500,000 tons; and generation of power, 100,000 to 200,000 tons.

The requirements of one representative system of preparing, conveying, and burning pulverized coal are 35 hp-hr. per ton. With a motor efficiency of 89%, this corresponds to a power consumption of 29.4 kw-hr. per ton.

Some systems require less power and others more, according to the methods used in pulverizing and conveying. Air transport systems require more power for their operation than mechanical systems, but have the advantage of greater simplicity and flexibility. Assuming an average consumption of 30 kw-hr. per ton, for the 10,000,000 tons used, the yearly power requirements will be 200,000,000 kw-hr. As many of the furnaces using pulverized coal have to operate fairly continuously, we will assume an average yearly operation of 5000 hours out of 8760. At this load-factor, the average power consumption will be 60,000 kw. If 2.5 lb. of coal are consumed in the power station per kilowatt-hour, this corresponds to 375,000 tons yearly for preparing and handling 10,000,000, or 3.75% of the total.

When burning other fuels there will be a corresponding charge which will vary according to the fuel and the method of firing. When atomizing oil with a steam jet, the amount of steam consumed is from 2 to 3% of the total steam generated in an oil-fired boiler. In addition, power is required for pumping the oil and for the blowers, which maintain the air-blast. This is an extravagant way of burning oil, but requires the least equipment. Pumping oil through mechanical atomizers is a more efficient method of burning. In power-stations, the stokers require power for actuating the fuel-feed, and for the under-grate air-blast. In addition, power is required for crushing and conveying the coal. With pulverized fuel the combustion is more complete and the stack loss is reduced. The result is that the net efficiency is a little better with pulverized coal under test conditions; and taking the human factor into consideration, it should be easier to maintain operating efficiencies

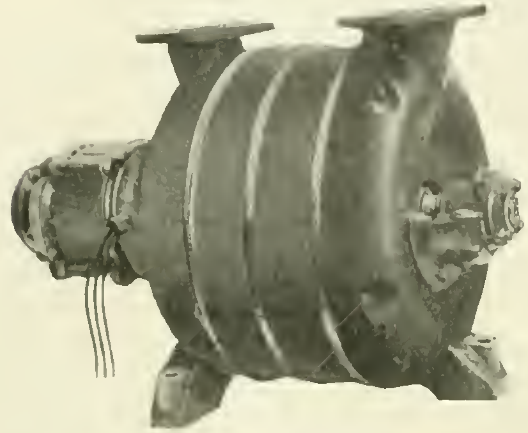


Centrifugal air-compressor with capacity of 3300 cu. ft. per min. at 1 lb. per sq. in. This machine is used for blowing pulverized coal into open-hearth steel furnaces.

---

*Abstract from 'General Electric Review'.

which are more nearly comparable to those attained in test. It is evident, therefore, that the power charges against the preparation and handling of pulverized coal are offset by the more efficient utilization of the fuel. By the use of off-peak power for preparing pulverized fuel the comparison can be made still more favorable and a margin provided to absorb other charges, such as labor at the pulverizing plant, when the installation is of sufficient size. If this be the case where the margin is smallest, it must be more marked in the case of metallurgical furnaces where the fuel saving is greater than is possible in a modern boiler-plant. Considerable fuel economies are possible, however, in boiler-plants having old-style stokers or where hand-firing can be superseded.



Three-stage centrifugal air-compressor with capacity of 250 to 350 cu. ft. per minute at 1½ lb. per sq. in. This type of machine can supply the primary air to pulverized coal burners at any pressure from ½ to 3¼ lb., by varying the number of stages from 1 to 6. The power required is from 2 to 8.5 horse-power.

LIFE AND COST OF SHOVELS

In a valuable paper on shoveling, prepared for the New York meeting of the American Institute of Mining Engineers in February, G. T. Harley had the following to say regarding the wear of shovels: To determine the relative wearing qualities and the cost per ton for supplying the men underground with new shovels, different places in the mine [Burro Mountain copper mine, Tyrone, New Mexico] were equipped with different makes and styles of shovels, and the results carefully noted. At frequent intervals, these shovels were measured to detect the wear of the blade, and checked up to see that all were being used in the proper places underground; the tonnage coming from each place, and the number of shovelers employed were also noted. The table gives the results obtained with the different classes of shovels.

		Tonnage handled by blades made of			
Type of shovel	Used on	Chrome-nickel steel	Secret composition steel	Common carbon steel	Extra light carbon steel
No 2 scoop..	Iron sheet.....	1220	950	750	...
No. 2 scoop..	Rough bottom..	....	...	...	...
No 2 scoop..	Wooden mat...	1500	1100	900	...
No. 4 shovel.	Iron sheet	990	770	629	250
No. 4 shovel.	Rough bottom..	1075	870	...	...
No 4 shovel.	Wooden mat...	1108	1000	730	340
Gage of steel in blade		15	13	14	16
Cost of shovel per ton handled, cents		0.0015	0.0018	0.0019	0.0026

The shovels made of chrome-nickel and special steel were excellent implements, but the special steel shovel was considerably heavier than the other. Cracks developed along the form line of the chrome-nickel steel blade, on each side, but these did not impair the shovel's usefulness. The blades of the three other shovels bent easily with rough usage, while the blade made of extra-light carbon-steel wore rapidly and the edges curled up almost immediately. The No. 2 scoop was used until its capacity had been reduced 25%, and the No. 4 shovel until its capacity had been reduced 9%. The cost of shovel per ton handled includes the cost of the shovel, freight, supply-house handling, handling new shovels into mine, and disposal of worn shovels. We had hoped to be able to detect a difference in the man efficiency on account of the different styles and weights of shovels in use at this time, but owing to the constantly changing conditions in the working-places selected for the trials, no conclusive evidence was available.

The wearing quality of any shovel used on an iron sheet varies from 74 to 86% of the wearing quality of the same shovel on a wooden mat, the average being 82%. The wearing quality of a shovel on a rough bottom is about 90% of that on a wood mat. These figures are based on about 50 observed shovels underground.

COMMERCIAL PARAGRAPHS

The **Chicago Pneumatic Tool Co.** announces the removal of its Cleveland district office from room 813 to rooms 406-408 Engineers building, effective March 1. Ross Watson, the district manager, will gladly welcome visitors to the new offices.

In Bulletin 180, the **Wood Equipment Co.** of Chicago describes its pneumatic rotary-dump machine for the rapid, safe, and economical unloading of mine-cars. This apparatus has great capacity. Such mines as the Alaska Gastineau, and many coal properties use them.

The **Wyoming Shovel Works**, of Wyoming, Pa., in its Catalogue No. 4, gives some interesting data on its 'Mayari red-edge shovels', which are of chrome-nickel steel. The sole agents in San Francisco are **Harron, Rickard & McCone.** All shapes and sizes and prices are given, besides many illustrations.

The **J. D. Fate Co.** of Plymouth, Ohio, has recently prepared a new catalogue, No. 4. It is a most attractive bulletin and is illustrated profusely with views of both underground and surface operations employing the Plymouth gasoline locomotive. This engine, which has found a wide market in the metal-mining industries, has been most favorably received by numerous companies all over the country, as shown in the present catalogue. It deals with the high efficiency and adaptability of the locomotive to both surface and underground conditions. The new publication will be sent upon request.

'Dixon's Graphite Products' is the title of a new pocket catalogue issued by the **Joseph Dixon Crucible Co.** of Jersey City. While not so complete as the large general catalogue, it gives a good idea of the variety of products made by this old concern. Pages are devoted to lists of articles especially for mills, railroads, automobiles, etc. The descriptions are brief, but the company will gladly send pamphlets dealing in detail with any of the individual members of the line. This new catalogue should be in the file of every purchasing agent, engineer, superintendent, and others who have occasion to use lubricants, paint, or pencils. Ask for Booklet No. 141-KP.

In order to give a practical working idea of what sizes of fuses to use for motors, the **Westinghouse Electric & Mfg. Co.** has prepared a series of tables. These are based on the size of fuse required to stand starting current without blowing. The proper fuse for a motor is only too often obtained by an electrician or a repair-man by haphazard methods. The motor's normal operating current is given by the maker on the name-plate, but fuses are properly selected of a larger capacity to allow for starting and for momentary overloads. Hence it is rather more unusual for the maintenance man to select his fuses by guess, with a view to their permanence in service rather than the safety of the motor they are supposed to protect.

EDITORIAL

IN this issue we give an abstract of the excellent speech delivered by Judge John F. Davis at the recent meeting of the American Mining Congress. His subject was the need for the creation of a Department of Mines headed by a member of the President's cabinet. As our readers will find, he made a good argument, which, we feel assured, will appeal to all those engaged in mining.

LIKE other minerals, tungsten is suffering from large stocks, imports, and low prices. Although $10 per unit is considered to be about the present price in this country, and $7.20 in England, we have heard of a contract for Oriental wolfram at $14.50. The new mines and plants at Mill City, Nevada, are closed. In our next issue we hope to give an interesting summary of the tungsten industry.

GOLD, as a standard metal, is the subject of two good letters under 'Discussion'. We refer elsewhere to Mr. McPherson's contribution. That from Mr. Percy A. Robbins came to hand after the other matter had gone to press. It will be noted that Mr. Robbins likewise presents the argument based on hoarding and predicts that it will prove an important factor in settling this problem of international finance. As most of our readers are aware, Mr. Robbins has been for many years the general manager of the famous Hollinger mine, in Ontario, the success of which is due largely to his skill and sagacity.

"A boom is on with a vengeance at Divide," writes an engineer from Tonopah, which is six miles from the new silver-gold district. New companies are being organized every week, and more than twenty shafts are being sunk. The only real mine is the Tonopah Divide, in which is blocked out several million dollars worth of high-grade ore at a depth of 375 feet. This mine is producing 35 tons daily of ore averaging $25 per ton. The finding of rich ore at other points in the district will be needed to sustain the boom, which seems to have fostered a litter of young wild-cats. However, much of the work is real mining, generously financed, and under competent advice. In our Mining Summary last week we gave a résumé of what is being done at Divide, and this week we give further news from our local correspondent.

DR. HENRY S. DRINKER, the president of Lehigh University and an engineer needing no introduction to our readers, has issued a reprint of an address made by him in January on the League of Nations, in which he mentions the fact that to Mr. Taft is due the credit for initiating—in June 1915—the movement in behalf of the League to Enforce Peace, which, in the hands of President Wilson, has become the basis for a League of Nations. It was the suggestion of pacifism that caused the words "to enforce peace" to be deleted by the European friends of the movement, so that in England and elsewhere similar organizations are entitled 'League of Nations', this sufficing to indicate the effort of thoughtful men everywhere to stimulate the representatives of the peoples in their striving toward the great consummation.

IN a recent speech Dr. David Starr Jordan pointed at the fact that the capitals of Europe are nearer to Washington today than were the capitals of the thirteen colonies in the early days of American independence. The development of systems of communication has not only brought human beings nearer in point of time but the development of various systems of telegraphy and telephony has annihilated distance. The 3300 odd miles of the Atlantic separates America from Europe today less than the 22 miles of the English Channel used to separate England from France in the days of Napoleon. The aeroplane promises to emphasize the change. Meanwhile there are good prospects that at last a tunnel will be built under the Channel, and there is talk of tunneling Bering Strait, so as to join the American and Asiatic continents, and thereby avoid the need for crossing the Pacific Ocean. Should aerial navigation be developed as is anticipated, the most distant parts of the world will be reached with a speed and an ease that will have an enormous influence in promoting acquaintance and goodwill between the peoples of the earth.

OUR boys, in writing from the army of occupation in Germany, express bewilderment on seeing the contrast between "the seemingly unscathed Germany and the devastated regions of France." When the German troops returned home after the Armistice they marched through the towns with heads up, singing, decorated with bunting, and deporting themselves like heroic victors. The people of the German towns occupied by the Allied troops take their shame without a shiver, they even make friendly advances to the soldiers of their enemies. What would happen if German soldiers were in conquering occupation of Sacramento or Denver? We can imagine, and so can our readers. The fact is, the German's mental processes are different from ours; we are unable to understand him. Think of the young aviator that killed Quentin Roosevelt talking about the pleasure he anticipated in going to the United States to live! He vanquished Theodore Roosevelt's gallant son fairly enough, but what real American would look upon him with admiration or affection for having done so? Many German prisoners talk glibly about coming to the United States, and even some of those who left the United States to cross the Atlantic and fight for Germany expect to resume their careers in the country whose hospitality they violated. We hope that they will be compelled to remain where they are and take their part in a kultur that they understand, and we do not. If immigration is to be restricted, it were well to keep an eye on these.

IN a recent appeal made by M. Georges Clemenceau in behalf of France to the United States, he refers to the suggestion of payment for trenches and for the graves of American soldiers in France as "atrocious". It was a vile canard started by some irresponsible journalist, and we are glad to take the opportunity to give this publicity to the denial. France merits our most friendly, respectful, and sympathetic consideration. She has suffered more than any of the Allies, she bore the brunt of the German onslaught, and she still holds the front trench of civilization. The loss of life, the ruin of industry, and the cruelties to her people caused by the German invasion are horrors that weigh heavily on the minds of the French and it is not for us to be impatient if they do not share our own—so much more detached and optimistic—views concerning the settlement of the account with Germany and her dupes.

HEARINGS held before the Mexican committee of the Council on Foreign Relations are said to promise a free ventilation of affairs in Mexico. The committee is thoroughly representative, for it includes Mr. Ole Hanson, the mayor of Seattle, now worthily famous, Judge Ben Lindsey of Denver, Mr. John Bassett Moore, formerly assistant-secretary in the Department of State, Mr. Alton B. Parker, and Mr. Frank P. Walsh. According to Mr. Mark Osmond Prentiss, who is described as the manager, it is intended "to tear the lid off the truth about Mexico and our citizens there." If American citizens are being "deprived of their rights, their property confiscated, and their persons outraged by responsible or irresponsible authorities in Mexico," he says, "we want to know it. On the other hand, if American interests or any other interests are fostering revolution there, we want to know it also." With that we agree; the one thing we deplore is a 'watchful waiting' policy that leads nowhere, but postpones indefinitely the hour of settlement and readjustment, which we, in common with the mining fraternity, have been anticipating year after year, ever since Porfirio Diaz was turned out of office and left Mexico to the free play of the forces of disintegration. If the Mexicans are not denied arms and ammunition, now on sale at many counters in Europe, we may expect further outbreaks of disorder. It is imperative that such imports be withheld not only at our frontier but at Mexican ports, as can be done by the friendly pressure of the Paris Conference, for the sake of the restoration of peaceful conditions in Mexico and for the good of the Mexican people, now harassed, despoiled, and famishing, by reason of continued revolts and vendettas. The committee to which reference has been made is one that will command confidence and it ought to be able to bring its findings effectively before the Foreign Relations Committee of Congress, the State Department, and the President. We wish it success in its useful labors.

IN an effort to bring about a more rapid resumption of business, the Secretary of Commerce has announced the formation of an 'Industrial Board', consisting of six members, whose function will be the stabilization of prices of basic materials. The names of three members of the Board have been announced, namely, George N. Peek, formerly vice-chairman of the War Industries Board, Hugh Frayne, representing labor, and Thomas C. Powell, now director of capital expenditures of the Railroad Administration. It is recognized that the present tendency of buyers to delay purchases in the hope of marked reductions is so general as to seriously paralyze industry. In order to lend governmental aid toward overcoming this condition, conferences are to be held with various leaders of industry in order to determine, as far as possible, fair prices for basic commodities. The first to be considered are iron, steel, lumber, textiles, cement, copper, brick, and other materials of construction. The findings of the Board will be valuable for their psychological effect only, as the Board is not empowered either to fix prices or to enforce them. Nevertheless, the announcement of what may be considered as a 'fair' price for any commodity, cannot help but produce its effect upon the buyers. There is nothing to prevent their buying for either more or less than the price determined upon by the Board if they can. It will be at least a reasonable assumption that little if anything can be gained by holding out for prices less than those determined by the Board.

MR. ROBERT LANSING'S speech on March 11 before the Inter-Allied Press Club in Paris was a weighty utterance and most timely in its frank analysis of the European crisis. Undoubtedly, as he made clear, the anarchy fostered by the Germans in Russia and now reducing Germany herself to a condition of bloody chaos, threatens to spread over western Europe with such violence as to shatter all plans for the restoration of order being devised by the Conference at Paris. The victors in the War are menaced by the consequences of their Enemy's disintegration. How much of it is deliberately planned in order to checkmate the efforts of the Allies to bring Germany to account, nobody knows; but it is evident, as Mr. Lansing says, that if the forces of social disorder are not soon controlled, there will be no organized Germany to bring to the bar of justice, only a mob of terrorists rampant over the ruins of Prussian misrule. When a burglar is injured while being captured by the police, it is usual to send him to a hospital, so that he may be restored to a normal physical condition before appearing in court to stand trial. So we must allow Germany to recover her sanity of mind and body before she will be fit to receive her punishment. Food and peace are the best weapons for killing bolshevism. We must make peace and relax the blockade without delay, not for the sake of the Germans, who are now getting some of their own richly deserved medicine, but in order to check the spread of the red terror and to save civilization, thereby completing the good work done by our armies and navies. Time presses. The representatives of the Allied nations, and their Associate, must act promptly and in unison, for the purpose of concluding the terms of peace, if the spread of this anti-social movement is to be circumvented. The desire to complete the organization of the League of Nations before signing the treaty of peace is causing delays that are dangerous. We realize the enormous complexity of the difficulties faced by the delegates at Paris, but we appreciate the wisdom of the appeal made by Mr. Lansing and we hope that this speech will make an impression in the right quarters.

Flotation Litigation

The hearing of the Minerals Separation v. Butte & Superior case before the Supreme Court of the United States was postponed from March 3 to March 19, on which date the matter came up for final decision. The judgment of the Court is not expected for several months and when it is made known it will not, we believe, be the end of the litigation over the patents covering the technique of the flotation process. Other issues remain to be tried. We have held to the opinion—and we hold to it still—that no single inventor or patentee has rights that give him the control of this branch of metallurgical industry; we believe that the process as now conducted so successfully and on so large a scale is the result of the ideas and efforts of a large number of men during the last twenty years. It would be a public wrong to give any patent-exploiting company the right to impose royalties and to interfere with the metallurgic operations of everybody using this process of concentration. We refuse to believe that a manifest injustice can be upheld for any length of time and we expect therefore, no matter what the ultimate decision may be in this particular case, that further litigation will be initiated with a view to asserting the rights of other patentees. Indeed, as we have remarked on a previous occasion, the opponents of Minerals Separation made a grave blunder in allowing themselves always to be placed in the position of defendants; they ought to have attacked Minerals Separation for infringement of older patents, such as those of Elmore and Wolf. The Elmore vacuum-oil patents of 1904 are now owned in this country and they ought to be asserted, for successful flotation was effected by means of them and by the use of a proportion of oil well within the so-called critical limits. The Wolf patent is not as well known, but it is significant in this connection. We refer to No 787,811, of J. D. Wolf dated April 18, 1905, for which application was made on May 22, 1903. It may be noted that Mr. Wolf, like the Elmores, had an unpleasant experience with Minerals Separation, culminating in a lawsuit, tried in 1905, in the course of which he claimed that the Minerals Separation metallurgists, Sulman & Picard, employed by him to investigate his process, had used the information obtained thereby and taken out patents in respect of discoveries that they made while in his employ. The Judge held that Sulman & Picard had fulfilled every obligation of their contract. In his patent Mr. Wolf, who is now in New York preparing for battle, describes an aerating mechanism for mixing the oil and the ore, for the production of a mineral bearing froth, which is withdrawn in a spitzkasten. The use of warm water is specified and the oil is one that has been sulpho chlorinated. He recommends mineral oil to which a little animal oil has been added before sulpho-chlorinating. We quote the full text of the patent on another page, so that our readers can examine it critically for themselves. This patent was recited in the Hyde case and both parties to that litigation appear to have agreed not to say too much about it, as would appear from the examination and cross-examination of Dr. Samuel P. Sadtler. It looks to us as if this patent might cover the main features of the flotation practice of today. We understand that an intelligent person unacquainted with the manipulation or the technique of the flotation process can obtain an effective mineral bearing froth by following the description and specifications of this patent. We recommend some of our readers to try it, forgetting for the moment what they already know about flotation. Of course, it is not surprising that either this patent or the Elmore vacuum-oil patents were not cited in the early litigations between Minerals Separation and American mining companies, because the latter feared to establish fresh royalty-hunting enterprises; they did not wish to run the risk of jumping from the frying-pan into the fire, but now that they have had a full taste of Minerals Separation methods any other patent owner looks friendly. Here we may refer to the Federal Trade Commission's inquiry into the doings of Minerals Separation. The hearing was held on December 31, the immediate result, so far as disclosed, has been to lessen the truculence of the Minerals Separation people, who appear now willing to revise their contracts as regards the manufacture of apparatus. We understand that the American Mining Congress is taking a hand in the matter, and we know of none more worthy of the attention of that organization. Nobody can forecast the opinion of the Supreme Court in the Butte & Superior case; if it sustains the Circuit Court of Appeals, all will be well; if it holds to the restrictive decision in the Hyde case, the outlook will be bad for the mining community. If the result should sustain the contentions of the Minerals Separation company, we advise our readers not to be dismayed and not to be driven into quick surrender. The flotation issue will not necessarily be settled by the decision on patent

No. 835,120. There are other patents, conflicting with this one, that are yet to be asserted, and through them relief may possibly be obtained.

Gold and Credit Money

Discussions concerning gold are of vital moment at this period when sober financiers are willing to consider economic experiments not less at variance with the old order than the freak State constitutions that became epidemic in the West some years ago. We are not now concerned with those legislative anomalies, some but not all of which represented proper and desirable social evolution, but we welcome letters such as that by Mr. John McPherson, in this issue, since they deal with gold, the thing that is fundamental in economics, because it is the basis of exchange. Critics may entertain divergent opinions on details, but Mr. McPherson and every other man who thinks seriously and with conviction on the problems of supply and demand, of production and consumption, of distribution of commodities, and the currency settlements involved, is contributing to the mental poise of the nation at a time when popular theories tend to lead away from the old tried practices. Some economic principles have been established which seem to be as fundamental and certain as biologic laws, but views change, and the physiocrats of one age are superseded by the conservationists of another; we swing from the idealism of individualistic free-traders to dreams of controlled free trade under a system of international 'allocation'. Nevertheless, through all the vicissitudes of social evolution there has been one unchanging economic fact: men have been universally agreed, apart from and above statutes and decrees, that gold in the hand will buy meat for the belly. The reasons why gold was selected as the supremely desirable metal to serve as a token of service with which to command the service of others has been discussed so often that we need not review them. The reason, however, for seeking and employing a metal possessing the well-known monetary attributes is not often brought into prominence. It is simply the fear of political disturbance. Banking is based on confidence. It is not merely reliance on the honor and integrity of the banker, nor belief in the wisdom of the banking laws, but faith in the stability of the Government, that admits of the development of a credit system. Granting such confidence, all manner of conveniences in the facilitation of exchange become possible. A smaller ratio of gold to the volume of business in terms of money then proves to be practicable. It is part of our belief in each other as social beings, as reasonable law-abiding men and women, that makes us content with the credit-paper that society gives its pledge to honor in the wares of daily need. One glance at Russia or Mexico, however, reveals why men insist upon available gold on demand as the basis for exchange.

In days of peace men laugh at tales of buried treasure. It is hard to realize, at a time when peace and security reign, that a preceding generation lived in the midst of alarms and subject to pillage by irresponsible and transitory officials, yet deep in the mind, like the instinct of a wild animal, lies the fear of danger that prompts us to desire the one substance for which men will exchange the food and clothing necessary for existence. It takes a long time to civilize the whirl out of a dog before he lies down; it has not yet been done successfully. Likewise, before the primitive desire for gold as a personal possession is supplanted by satisfaction with a piece of paper as the only representation of a claim on this world's goods as a return for service rendered, it will be necessary that many generations shall have grown so accustomed to the undisturbed enjoyment of the refinements of social organization that they may count upon the stability of the new order as firmly as on the daily rising of the sun.

The significance of this psychology of the demand for gold is that the royal metal will not be retired from its ancient duty as real money. To internationalize the gold reserve would be equivalent to retiring it, but the reaction would be so prompt and so pronounced that the attempt to initiate such a scheme would defeat itself. This, however, does not settle the question that so deeply concerns the gold miner, which is the purchasing power of the bullion produced. If gold mining were to cease, the demand for payment in metallic currency would increase, and a further rise in prices undoubtedly would follow on account of the different esteem on the part of the public for credit-money and for hard cash. This would encourage an outside market for gold where a normal ratio to commodities would assert itself. Ordinarily we would hesitate to offer suggestions of this character, but the time has come, not for ultra-social experiments in finance, but for grappling firmly with the concrete problem of giving to gold such a relation to exchange as will admit of continued profitable production of the metal, so that a reasonable amount may be forthcoming to serve as a safe basis for the currency-expansion required by the increasing population of the earth and the growing magnitude of commercial transactions. Retiring gold into the financial background will not do while the Bolshevists are raging in Russia, while the I. W. W. hamper industry in the United States, and while the Premier of England openly warns his country of the danger of civil war. The best antidote for revolution is the surety of opportunity to make a due amount of money for one's needs by peaceful industry, and to receive payment in something that is convertible into gold on demand. With gold mining on the wane, with the shortage of gold leading financiers to discuss cobweb designs of a frail beauty, it is evident that serious consideration of this problem should not be deferred. In the interest of the public welfare the restoration of gold, as a measure of value compatible with the measure of the effort required to get it, is imperative. This does not mean that we must 'raise the price', or juggle with the standard, but it does mean that we must find a way, without incurring disaster, to bring credit-money back to the level of the real.

DISCUSSION

The Status of Gold

The Editor:

Sir—The article by Van Dyck entitled, 'The Status of Gold', appearing in the 'Mining and Scientific Press' of February 1, 1919, contains so alluring an aspect of feasibility that its pitfalls of fallacy are not immediately apparent. In casting about for a ready solution of the much-discussed gold problem he has hit upon this proposal: 1. That all gold be called in and paid for at \$20.6718 per ounce, and that all silver be called in and paid for at \$1.015 per ounce. 2. That the monetary value of gold be fixed at double the present, that is, at \$41.3436 per fine ounce * * * 3. That all newly-mined gold be paid for at the newly-stabilized price. 4. That all metals so accumulated be coined as needed. 5. That all coin be released freely as called for from any quarter of the globe.

In brief his proposal is that the Government take every gold coin, melt it, and re-stamp it with double its present face value. In this manner the present-day confident face of the 'twenty' would re-appear tomorrow stamped 'forty dollars', without any change in weight or bulk; or perhaps the Government would decide to make two coins of 'twenty' each out of one present twenty. Mr. Van Dyck would thus supplant the printing-press manner of making money by the mint-stamp method; yet he would laugh in reasonable merriment at a Mexican leader or a Bolsheviki ruler who should order the printing presses to start as the nation was running short of money to pay foreign debts, or any debts. "It must be borne in mind," he says, "that legislation cannot bring gold into existence," but he implies that legislation can double its purchasing power.

One might reasonably ask why the Government should waste labor and time in melting every twenty-dollar coin and re-stamping the gold into forty dollars when a quick and handy plan would be to leave the twenty-dollar coin as it is but strike as many brass discs as there are such 'twenty' coins, stamp each brass disc "twenty dollars" and shackle one of these discs to each twenty-dollar coin, thereby making, by Government authority, a twin gold and brass coin of forty-dollar purchasing power? While this method would economize time and labor it would be as powerless as the ounce of gold with the forty-dollar stamp on it to reduce the ratio between paper money and real money, between symbol money and money carrying its value around in its own body. This gold-brass twin coin illustration is given to demonstrate more clearly the fact that one half the coin is real money and the other half symbol money. This is exactly what the present twenty-dollar coin would be when it should have received its new stamped face.

What is this subtle mystery in the process of exchange that prevents any nation from stamping an arbitrary figure or figures representing value on the face of any metal disc, gold included? There is only one thing that prevents it, and that thing is the intrinsic or social value of the given metal. Is there any difference in intrinsic value between a disc of brass stamped 'twenty dollars' by the Government and a twenty-dollar paper note? There is no difference; they are both symbols of value and do not contain within their physical or chemical bodies the value they represent. The gold-metal disc, provided it is stamped with its current value on the face, carries always with it, within itself, its own actual value in metal bulk and weight. This actual value is always approximate to that marked on its face. 'Approximate' is used advisedly because there is a constant invisible fluctuation in price of the metal which would be revealed in arithmetical figures in a free market only.

By acting on Mr. Van Dyck's suggestion the gold coin, as if by enchantment, should double in purchasing power at the instantaneous drop of a mint-stamp; where the twenty-dollar gold piece procured but ten bushels of wheat at two dollars per bushel yesterday it would purchase twenty bushels today! If it were possible for any nation to perform such legerdemain as this it would be equally possible to act similarly in regard to the case of the wheat which Mr. Van Dyck gives. He says: "Assume that our country has a debt of \$30,000,000,000 to pay, and assume that we are now in a position to pay it with 15,000,000,000 bushels of wheat at two dollars a bushel." The Government could as easily leave gold as it was, and arbitrarily fix the price of wheat at four dollars per bushel, or double the price of any commodity it was sending to pay the debt. What could be more preposterous than this? Fancy the astonishment on the face of the Chinaman or the Japanese, for instance, when he should receive one bushel of wheat instead of the two bushels he expected; or, imagine his protest if he should receive but half an ounce of gold when only the day before there was agreement to pay him a full ounce!

If any nation or group of nations can double the figure on the face of a gold coin, or on the face of an iron coin for that matter, that nation or group of nations can as easily treble it, or quadruple it, or multiply it by tens or by hundreds. There is, however, one obstacle always in the way of this, and that is the intrinsic and social value of the metal itself. This social inherent value is what renders it useful as a measure of the value of all other commodities. Any metal, gold included, derives this value from the amount of social human energy and time expended in its production. It is a fallacy to assert that the law of supply and demand regulates this value. It is true, of course, that supply and demand have the effect of raising or lowering the price of a metal in a free market, but the price does not by any means always indicate its value. The price may be sometimes above, sometimes below, its value according to the social and human circumstances of the occasion. An increase of population with no increase of gold production would undoubtedly have the same effect on price as a corresponding decrease of production with no increase of population.

There is virtually only one buyer for gold and that is the Government; therefore free competition is not seen in its natural action. It is difficult to determine what the price of gold would be if every banking institution were allowed to buy and coin its own metal. Undoubtedly the price would rise for a time at least, but would drop again as the relations between nations became more stabilized and international confidence became more firmly established. Gold is called into active functioning as a monetary metal during war times owing to its being a metal high in actual value in proportion to its weight and bulk, and therefore easily transferred from one country to another. It also carries around with it, in the form of social energy-value, the security necessary to settle payments from nations whose stability is at the moment more or less uncertain. Iron money, brass checks, or paper, do not possess these characteristics, and if gold coin itself were arbitrarily stamped with figures far above its intrinsic value it too would not possess complete security as a measure of value; it would possess its original intrinsic social value and the difference between this and the figures stamped on its face would be fictitious.

JOHN MCPHERSON.

Seattle, Washington, February 14.

The Editor:

Sir—On January 13, 1917, I published in the Toronto 'Saturday Night' an article upon the gold situation, in which article I advanced the argument that the standard of gold should be changed to $30 per ounce. My suggested plan was that the Crown should commandeer all gold, paying for it upon a sliding scale; for a period of 15 years, payment to be made $22.50 per ounce to all mines in operation prior to the enactment of the measure; $25 per ounce to old mines that have been closed down through inability to make profits at the old value of gold; $27.50 to new mines discovered after the enactment of the decree. It was understood that this arrangement would be entered into between Great Britain, France, United States, and Russia, and it was assumed that all coin and plate commandeered would be paid for at $20.67 per ounce.

I submitted the article to both yourself and to Mr. Ingalls of the 'Mining Journal', for comment, but failed to get a 'rise' out of either of you. Inasmuch as both the 'Press' and 'Journal' subsequently published a number of discussions upon the subject of the gold standard, and as their columns reflect current thought, I take it that I erred in being somewhat too early with the suggestion. Later, in May 1917, I published a second article giving further arguments in support of the proposal.

The criticisms aroused by these articles were remarkable for their paucity of ideas, the stock arguments being, "It can't be done" and "if you raise the base of values in gold you will raise the values of everything else." During the past eighteen months many articles have appeared, and everyone interested in the problem is by this time thoroughly conversant with the arguments. The findings of both the American and British committees, being against any adjustment of values, would seem to put a quietus upon further argument, but the excellent letter of Mr. Van Dyck in your issue of February 1 prompts me to again attack the problem.

Mr. Van Dyck points out that before the War the ratio of gold-supply to indebtedness was about 1:3 and at present it is about 1:15. Now, either gold reserve does perform a function or it does not. If the ratio 1:3 was a sound condition before the War, then the ratio 1:15 is unsound. If 1:15 is a sound condition, then we were all wrong in our ideas before the War. I do not see how we are to avoid the conclusion that something is wrong somewhere in our financial standards. Mr. Hennen Jennings used a unique explanation of the function of gold in calling it a storage-battery of human energy; its value represents a certain amount of labor at the command of the possessor of gold.

In 1812 Great Britain determined the quantity of energy so stored in a unit of gold, and gave gold its present nominal valuation. At the time of fixing this value Great Britain needed money for settling war-bills, and she set about raising these funds by issuing Consols,* or government bonds. Her proposition was this: To every person who would give her £100 in gold she would give a piece of paper stamped £100, and forever thereafter the holder of this piece of paper would have a right to a certain amount of the wealth produced per annum by the combined labor of the British empire.

This was collective bargaining. The producers of Great Britain through their government representative said, "We are in debt; we need money; we do not want to borrow money; we do not want to confiscate money, but we must have money; now therefore we make this proposition to you who have money: we will give you a bond upon ourselves and our progeny throughout all generations, and the holder of that bond will forever receive from us a certain amount of the wealth produced by us annually." That is to say, in exchange for immediate gold, the Empire offered the products of future labor.

The holders of gold accepted this offer, but it was necessary that some definite base-value of gold in relation to labor should be fixed, for the interest to be paid was to be payable in gold. So it was decided that one ounce of gold should have a monetary value such that the expression £100 would for all time mean the same Troy weight of gold. In 1812, therefore, a man with one-hundred standardized sovereigns was willing to exchange them for a Consol bearing the denomination £100.

---

*'Consols' is an abbreviation of 'consolidated annuities'.—Editor.

After the passing of a century we find that our forbears arrogated too much wisdom and power to themselves; their 'fixed' gold-value no longer holds good. For many years the Bank of England has maintained its reserves in gold and Consols. When gold became scarce, Consols were taken out of the vaults and exchanged for gold. When too much gold was accumulated, it was got rid of by exchanging it for Consols. But the exchange has not always been made upon the same basis. During the Boer war Consols sold down to 85; during the European war they sold as low as 51½; and 59 is about the present value of Consols.

The meaning of this is obvious: the man with one hundred standard sovereigns will no longer exchange them for a Consol bearing the inscription £100. He knows that his golden sovereigns will purchase more labor in other markets. He is not willing to receive such a small annual return from the British empire as his great-grandfather was satisfied with.

Now bear in mind that Consols are not payable in the labor of any particular generation, they are payable in the labor of the present and all future generations, and in fixing the labor equivalent of an ounce of gold Great Britain assumed to do so for all time. The fair equivalent in 1812 was that one hundred sovereigns in gold were worth the future labor pledged in a Consol bearing the inscription £100. The fair equivalent in 1918 is that 80 sovereigns in gold are worth the future labor pledged in a Consol bearing the inscription £100. In other words, the investment value of an ounce of gold in 1918 was 25% greater than it was in 1812. Gold has enhanced 25% in its labor equivalent. The stability of the British empire as a going concern may be questioned; owners of gold may not consider it as stable as it was in 1812. The danger of a political upheaval may cause the extremely cautious to hoard gold, rather than that they hoard Consols.

Gold has always been hoarded, it is as natural for human beings to hoard gold as it is for squirrels to hoard nuts. Through ten thousand years of growth, black, yellow, and white men have learned that under any conditions of life or politics, where men have some commodity to exchange, they will exchange that commodity for gold. The amount of gold demanded may vary, but our fundamental knowledge of finance is that a man with gold can always get something in exchange for it. It is, as Mr. Jennings says, a storage-battery of human energy, and while at times the battery may need re-charging, yet at all times it has been capable of giving out something; it has never yet completely 'run down.'

When a man accumulates wealth, he must have some means of proving that he possesses wealth. He may buy diamonds, automobiles, clothes, and a house, and put all of his wealth into such visible objects. He may exchange his credit for gold and hide the gold; this is done to a large extent throughout the world. The usual method, however, is for him to purchase securities, with the idea that he may at any time convert them into gold or diamonds or automobiles or food, as fancy or need dictate.

All securities to be of value must be guaranteed by other men, for a commercial security is a bond upon the productiveness of men, and the holder of a security only has command over that productiveness in so far as other men are prepared to accept that command. A bond of a city is more secure than a bond or note of an individual; and a bond of a nation is more secure than the bond of a city. Among the nations the degree of security is accurately reflected by the interest rates paid for loans by the various governments, and at the present time, the United States presents the greatest security. But at the present time there is great unrest throughout the world, and we are not at all certain that future generations will live up to our present-day guarantee. Our successors may repudiate our promises.

This has happened in Great Britain; the present generation repudiates the relation established in 1812 between labor and gold. The greater the political disquietude, the less secure are the guarantees of political states, and as these guarantees become less secure, the potential value of a hoard of gold becomes greater. The individual looks to the possibility of a disruption of political bonds, when in the state of chaos which will follow, men will barter between themselves for their needs; when the man with gold will be able to get something for it; when securities will be unsaleable or valueless. Therefore for purposes of hoarding, gold has an enhanced value over government securities, for today a man with 81 gold sovereigns will hoard them rather than hoard a British Consol of £100 denomination.

Thus we see that, either as applied to active interest-earning investment, or as a hoard of wealth, gold has a greater labor equivalent than was ascribed to it when the weight of a pound stirling was fixed.

The fixing of the weight of the British sovereign and the issue of Consols constituted a definite appraisal of the value of labor expressed in terms of gold. The value was arrived at by taking the value of an ounce of gold as expressed in terms of monetary nomenclature on the day that act came into effect. Upon the same basis today gold is selling at an enhanced value of 25%.

I maintain that with the present unsettled condition of the world, if gold were demonetized, it would immediately rise in comparative value, this claim being made upon the basis that the possession of gold is an absolute and incontrovertible fact; while the possession of a command over future labor, as guaranteed by government or other securities, is a suppositive possession.

An analysis of the status of British Consols today seems to indicate that clipping 20% from the weight of a soveriegn is not only justifiable but is necessary in order to restore the natural balance between gold and labor, and a further reduction in the weight of the sovereign is justifiable in the light of an analysis of the relation between gold supply and indebtedness. The present weight of the sovereign seems bound to incite private hoarding by individuals and banking interests, and this condition will increase labor troubles. The wealthy man today has every incentive to convert a large part of his wealth into gold, not only on account of the insecurity of investments, but because he can beat the inheritance tax by creating an untraceable hoard of gold, for the benefit of his heirs.

It seems to me that re-coining at one-half or two-thirds of the present weights of gold coins is a matter which merits a continued discussion.

P. A. Robbins.

San Francisco, February 11.

Spelling Reform

The Editor:

Sir—I agree in the main with an editorial note in your issue of February 15 regarding simplified spelling, that it is best as far as the A. I. M. E. is concerned to leave these matters to the committee on publications, but if the members can assist the committee toward a decision in favor of certain moderate reforms that is a different matter. I am sure that many spelling reformers do not aim at "unpleasant and unnecessary changes," as some proposed changes make for greater convenience. For instance, the usage is not uniform in dropping the final e of a primitive upon adding a suffix beginning with some consonants, as in 'abridgment' and 'judgement'. The Simplified Spelling Board advises that the final e be dropped in all cases, thus removing an element of doubt and real annoyance to some writers without incommoding or startling anybody except proof-readers.

We should not ignore the fact that good usage in spelling is not fixed but is changing before our very eyes, the virus of rather rapid change having found its way into thousands of schools, a hundred colleges, and the best dictionaries. It was only twenty years ago that the National Educational Association adopted the "twelve words" with the spellings, tho, thru, catalog, etc., but they are now in use by many good publishing houses, and the time will soon come—I believe now is—when these shorter spellings should be regarded as good usage. In the 18th century these and other shorter spellings had the sanction of the highest literary authority and the abandonment of these forms shows that our spelling has been changing, in this instance at least, for the worse.

In the prayer-book Psalter, among other old spellings, occurs the spelling "slipt" for slipped. If you ask a professor of language and literature about this, he will probably say that the shorter spelling is the proper one to use only in elevated metaphor, but the real fact seems to be that in printing successive editions of the Book of Common Prayer the publishers were not allowed to follow the changes of fashion in spelling and for that reason the shorter and strictly phonetic form has been preserved.

I sympathize with your general position in the matter, because no author has a right to distract the attention of his readers from the subject by spellings so unusual as to appear grotesque, but this matter is receiving such earnest attention from educators that it behooves us to walk somewhere within hailing distance of the procession. One well-known university has not endorsed this reform because the dean of the college in which English is taught has no patience with the 'Bad Boy's Diary', but the execrable spelling of his students has driven him to the advocacy of a less practicable scheme, a phonetic alphabet of over 40 letters. That a few of us can spell is beside the point, because we learned spelling at a time when the younger scholars studied very little else. I spelled while I filled the wood-box and fed the chickens and when too young to stand up in school I would spell a hundred times the hard word on which Mary Ann spelled down that up-river school. However, our children are too busy to fill the wood-box, feed the chickens, or even to spell, and the professors say we must make spelling easier. I am inclined to think that some day the idea will be exploded that the word-form containing the most letters is the most dignified.

John Randall.

Mogollon, New Mexico, March 1.

[We are not unwilling to publish this reasonable letter, but no further discussion of the subject will be accepted. —Editor.]

Good analytical weights are made of three metals: 2 grammes and over of brass, gold plated; 50 to 1000 milligrammes of platinum; and 1 to 20 milligrammes of aluminum, according to H. D. Greenwood of the Chrome, New Jersey, refinery of the U. S. Smelting Co. For the lesser weights, platinum is the best, as it is hard and wears the least; but weights of 1 to 20 mg. made of platinum are so tiny that they slip from the forceps, and the assayer spends too much of his time and patience looking for lost weights. Aluminum being a lighter metal, the weights are larger and easier to handle. It does not wear well, and the constant picking up of the weight with forceps wears off small particles, making the weight lighter than it should be, and a light weight means a high assay. For example, if a weight should wear away 0.02 mg. in the course of a year, the assayer reports 0.02 oz. gold or 40 cents more on every ton of material coming into the plant than is actually in the material, and on a yearly tonnage of 120,000 the loss would be $48,000. Similarly, copper and silver are also affected. Weights are listed by the makers and dealers through 11 stages, from medium accuracy to extremely accurate, with prices to suit. The Chrome laboratory recognizes only the seal and certificate of the Bureau of Standards, for calibration of weights.

Magnesite production of Canada fell off last year from 58,090 to 39,365 tons. Quebec is the only Province yielding this mineral. The proportion of calcined and dead-burned clinker is increasing. The latter is sintered in rotary-kilns after being mixed with 5% of iron ore (magnetite). Prices were $9.50 per ton for the crude, $25 for calcined, and $35 to $40 for dead-burned product.

A Federal Department of Mines

By JOHN F. DAVIS

*In California the idea of advocating a Secretary of Mines in the Cabinet is not a new one. I remember when the old California Miners' Association took it up; and back in 1898 I remember hearing Mr. Tirey L. Ford, afterward our Attorney-General, make an address in favor of the creation of a Cabinet position of Mines and Mining. It is not a new idea in other communities. It is true that England has no such Cabinet position; but there are such departments on the Continent. There is a Department of Mines in Canada, in South Africa, and in Australia.

The great trouble in getting a Department of Mines and Mining in the United States has always been among the miners themselves; to get the miners thoroughly to understand the necessity of such a proposition, and to dispel false ideas of what is involved. You will remember that the last time we took it up it was a part of the mining community itself, or rather, of a prominent representative of it, that defeated the proposal. We had it almost within our grasp, and yet the historic fact is that the reason that the campaign for a Cabinet officer of Mines and Mining was not pushed to final success was the attitude of Senator Teller of Colorado, who insisted that the Cabinet of the President had already become top-heavy, too large, and too numerous; and he picked out the very industry in which you would think he ought to have been interested to stop the creation of additional memberships in the Cabinet. The proposal had to be abandoned, and we had to compromise on a Bureau of Mines as a substitute therefor, or a nucleus for future work, and even that Teller opposed.

Now I feel that the very first thing we should do is to dispel any impression that there is any antagonism to the Bureau of Mines involved in the creation of a Cabinet office of Mines and Mining. Nothing is farther from the fact. It is the inspiration that the Bureau of Mines has given us that makes us feel that the time has now come to ask for a Cabinet office. It is the success that the Bureau of Mines has made that encourages us to believe that we may now go to the country and, as it were, ask for the next step in promotion for the industry. It is the Bureau of Mines itself that is back of this very proposition. It finds that it cannot do all that it would like to do; it finds that it cannot do everything with the same ease that other industries have found at their disposal when they advocate some great measure in their industry; it feels that the time is ripe now for the mining industry to be graduated from a Bureau of Mines into a Department of Mines. Instead of its being in antagonism to anything that now exists in defence or in behalf of mining at Washington, this movement is something not only in accord with what we already have there, but it is promoted by the Geological Survey, by the Bureau of Mines, and by the American Mining Congress.

It would be the worst thing in the world if, from anything that was said or done in San Francisco at this session, any false impression should be created that this movement was anything in promotion of Government paternalism; that this movement was anything that was back of a scheme under which the Government might be reaching out to obtain control and ownership of the mines of the United States. Instead, the motive back of this proposition is the diametric opposite, namely, that if the time has come when certain industries will now again be conducted under individualistic control, we find that if the industry of mining is to have an even break with other interests that are already represented in the Cabinet, it must have, like them, its representative in the Cabinet of the President of the United States. And so, instead of this being anything in aid of reaching out for an unfair control, the idea is that mining shall not only be on its own basis, and conducted on its own individual merits by individuals and corporations, but that these individuals and corporations shall have the same aid, or at least have the same opportunity to bring about proper legislation for its protection and its advancement, that agriculture, that commerce, that labor, that any other equally important industry in this country has already. The great trouble is that we have not always realized in America just what the importance of mining is, what constitutes its importance, that is, its relative importance to other industries; and I imagine that much of this feeling throughout the United States has come from the fact that out here in California, until the War, we were mostly interested in gold mining, and, therefore, we partook of a certain isolation in the domain of mining. We had even here built up an idea of a common law of mining that was different from that of any other part of the country; the very tenure of these mines was different; and, at the risk of detaining you I shall read just one paragraph of the Report of Major Powell of the Land Commission of 1880, in which he calls attention to that fact in the most succinct way.

He calls attention, in the first place, to the fact that the gold prospectors out here were in the eyes of the law mere trespassers on the public domain; there was no national law existing over this domain in California at the time. They simply were invaders and trespassers. "Finding themselves far from the legal traditions and restraints of

---

*Abstract of an address delivered before the California Chapter of the American Mining Congress at San Francisco, on January 16, 1919.

the settled east," he says, "in a pathless wilderness, under the feverish excitement of an industry as swift and full of chance as the throwing of dice, the adventurers of 1849 spontaneously instituted neighborhood or district codes of regulations, which were simply meant to define and protect a brief possessory ownership. The ravines and river bars which held the placer gold were valueless for settlement or homemaking, but were splendid stakes to hold for a few short seasons and gamble with nature for wealth or ruin.

"In the absence of State or Federal laws competent to meet the novel industry, and with the inbred respect for equitable adjustment of right between man and man, which is the inheritance of centuries of English common law, the miners only sought to secure equitable rights and protection from robbery by a simple agreement as to the maximum size of a surface claim, trusting, with a well founded confidence, that no machinery was necessary to enforce their regulations other than the swift rough blows of public opinion. The gold-seekers were not long in realizing that the source of the dust which had worked its way into the sand and bars, and distributed its precious particles over the bedrock of rivers, was derived from solid quartz veins, which were thin sheets of mineral material enclosed in the foundation rocks of the country. Still in advance of any enactments of legislature or congress, the common sense of the miners, which had proved strong enough to govern with wisdom the ownership of placer mines, rose to meet the question of lode claims, and decreed that ownership should attach to the thing of value, namely, the thin sheet-like veins of quartz, and that a claim should consist of a certain horizontal block of the vein, however it might run, but extending indefinitely downward with a strip of surface on or embracing the vein's outcrop, for the placing of necessary machinery and buildings. Under this theory the lode was the property, and the surface became a mere easement.

"This early California theory of a mining claim, consisting of a certain number of running feet of vein with a strip of land covering the surface length of the claim, is the obvious foundation for the federal legislation and present system of public disposition and private ownership of the mineral lands west of the Missouri river. Contrasted with this is the mode of disposition of mineral bearing lands east of the Missouri river, where the common law has been the one rule, and where the surface tract has always carried with it all minerals vertically below it.

"The great coal, iron, copper, lead, and zinc wealth east of the Rocky Mountains, have all passed with the surface titles; and there can be little doubt that if California had been contiguous to the western metallic regions, and its mineral development progressed naturally with the advance of home-making settlements, the power of common law precedent would have governed the whole mining industry. But California was one of those extraordinary historic exceptions that defy precedent, and create original modes of life and law. And since the developers of the great precious emtal mining of the far west have for the most part swarmed out of the California hive, California ideas have not only been everywhere dominant over the field of industry, but have stemmed the tide of Federal land policy, and given us a statute-book with English common law in force over half the land and California common law ruling in the other."

That is the situation, and that is one reason why we were never able, when our industries were confined to gold-mining alone, to get that hearing and that audience to which we felt we were entitled from people who owned mines containing metal of any kind east of the Missouri river. That was the reason why we were never able seemingly to get the co-operation which there is an opportunity to get today.

Now the effect of the lack of standing of gold production, under the inaction that we have had, without that initiative for the benefit of the industry which would come from a Cabinet office of Mines and Mining, was probably well illustrated by what happened in this country not long after we entered the War. You will remember that America had not been long in the War when all of a sudden rumors began to come out of Washington with reference to a question that was mooted in the Priorities Board, whether or not that Board was going to give opportunities for transportation or manufacture to anything except war essentials; and soon men in California, who seemed to be drifting along in gold mining in a blissful inaction that was simply incomprehensible, were amazed to read in the dispatches suggestions that it might be contended in certain quarters in Washington that gold was a non-essential of war. Of course we Californians never for a moment believed that any such theory would gain a hearing anywhere in the United States, for every one of us had read in the history, not of California, but of the United States, that the great crowning glory of California at the time of the Civil War was that this State, though far removed from the scene of the conflict, so far that it could contribute only a small quota in man-power to the conflict, had actually helped to save the day, because in California we had found the gold and had produced the gold that had saved the credit of the United States.

And so, when those first rumors began to come out of Washington, it was impossible for our people to believe that there was anything back of them; and yet they grew apace, so that the first thing we knew we found that not only were the rumors true, but that there was no representative of gold mining on the Priorities Board at all; and it was not long before Mr. Hennen Jennings came out here, palpably aroused, pleading with us to get up some propaganda of reflex action and sentiment to convince Washington that gold actually was a war-essential, and that no such order as was feared must ever be allowed to be made.

Then it was that we began to realize that, by reason of the fact that we had no special representation in any Cabinet office, a great essential industry was in danger of being ignored or even paralyzed. We actually formed a committee on gold, which went out over California and the West, which held hearings, at luncheons and dinners, that committee being composed of Hennen Jennings, John H. Mackenzie, and Charles Janin of the U. S. Bureau of Mines, and F. L. Ransome of the Geological Survey. They formulated a report, which was presented on October 30, 1918, vindicating the production of gold as an essential war measure, twelve days before the Armistice. Of course, long before that the result of their important work was known in Washington, and so the proper order was finally made by the Priority Board. But when you think of the position into which gold production as an industry had fallen, you will realize that there is something wanting in the representation of this industry at Washington.

And if that incident does not convince you of the fact, let me then give you the absolute statistics of the production of gold during this war. Now, the production of gold in the United States, including Alaska, for the year 1915, was $101,035,700; in 1916 it had declined to $91,307,630; in 1917 it had declined to $83,750,000, and in 1918, to the first day of January 1919, it had declined to $68,493,000. In other words, you cut it nearly in half, when you stop to think that on January 1, 1915, it was nearly $102,000,000, and on January 1, of this year, it had declined to $68,000,000. So it would look as if the familiar reference to gold as the 'royal' metal was in danger of serious revision; and that De Launay, the French author, when he issued his book on mining that has just come out, was not far from the fact when he said that coal and iron are now "the *grand seigneurs* of the mineral world," and that the ancient idea that gold was the royal metal was fast disappearing, and that the new measure of value was the usefulness of a metal. We of California, I think, might be tempted to say to De Launay that he might have added oil to his list.

When you stop to think of what started this world-war, where the seeds were sown, you may well come to the conclusion, not only from the incident that you almost had gold declared a non-essential of war, but from this marked decrease in the production of gold you may begin to realize the tremendous importance of other metals besides gold in the mining world. Away back in 1870 the seeds of this conflict, as far as Germany was concerned, were sown. You will remember that in the peace conference at the end of the Franco-Prussian war the question whether or not they would take Alsace and Lorraine was the great question debated at Versailles; that Bismarck opposed the acquisition of Alsace and opposed the acquisition of Lorraine, whether he intended to be taken seriously or not. At any rate, he opposed it *pro forma* on the score of the race question, and the legacy of *revanche* that would be involved in taking them; and you remember that in that debate Von Moltke and the rest of the General Staff protested, and urged that Alsace must be taken and Lorraine must be taken, because the new German empire then created could not afford to have on its border the two great forts of Metz and Strasburg; and yet we now know that, no matter what was the camouflage of the debate, the real reason was that it would never do to take a chance not to get the iron of Alsace Lorraine, and that the real reason for the taking of Alsace and Lorraine was the existence of the iron deposits, not the forts of Metz and Strasburg. And who is going to say that when this war was precipitated one of the great reasons why it was precipitated may not have been the opportunity to get the iron mines of Briey, and the coal mines in the Department of the Nord and the Pas-de-Calais, in northern France, and the opportunity to get the oilfields at Baku and the minerals in the Urals?

We begin to realize as part and parcel of the outcome of this war the tremendous significance of the ownership of oil, of iron, and of coal; and it is about time that we began, in California especially, after the experience we have had in the mining of the baser metals during this war, to wake up to a realization of what mining now means, and what economic geology now means to the world. I cannot do better than to quote a very short paragraph from the recent report of George Otis Smith, the head of the Geological Survey at Washington, in which he uses these words:

"Economic geology is useful geology—the theoretical science applied to meet the material needs of man. These human needs as presented in the last four years have demanded a specialized type of geology—*the application of geology in terms of commerce*. Geology to be most useful in these days of world problems must take the world view of values, and we find ourselves working in commercial geology—that is, geology applied in terms of commerce. The world is the field of commerce, and the requirements of commercial geology are simply that the geologic relations of a Nevada ore deposit, for example, must be observed with an eye trained to see far beyond the Basin range; the geologist needs to compare the quality and quantity of the unmined ore here with similar facts of nature that give value to the ores in other districts, as in Peru or Burma. Whether the investigator is called a geologist, mining engineer, or economist, his vision must take in not simply the ore minerals as they have been deposited, segregated, or enriched by the processes of nature, but also the smelted ore and the refined metal on their way to the markets of the world where they can serve mankind. Thus to broaden and extend the investigator's view is not to commercialize his science; it is rather to make geology more useful, and in that way to give the science a higher rank. Geology must needs continue to furnish the basal facts, but the geologist has a call to go further than he has gone heretofore in the interpretation of his facts—not simply by translating his technical words into the language of the market place, but, more than that, by showing *the relation of geology to national life*."

You remember that when the War grew apace we were confronted with the question of enacting a War Minerals bill. If ever there was an illustration of how little representation we had at Washington in comparison with banking, with labor, with commerce, with agriculture, for the obtaining of necessary protection, it was illustrated in the preparation of the War Minerals bill. That bill with all the aid that could be given it by the Geological Survey, by the Bureau of Mines, by the American Mining Congress, by every other authority that got back of it and promoted it, took until the 5th of October, 1918, in order to get enacted into law. The President did not sign the order transferring the operation of it to the Secretary of the Interior until the morning of November 11, and by noon the Armistice had been signed, and it lay there nine days undelivered, and everybody seemed to have forgotten its existence. Would that have happened if we had had a Department of Mines with a Cabinet officer at the President's table? Then, when it came to relieving a crisis that had been created by the Government in its effort to urge the chrome men and the manganese men and the pyrite men and others to speed up and to spend money patriotically borrowed in order to provide the Government with the necessary material to carry on this war, then there was a scramble to see what help, if any, could be obtained from the War Minerals bill. It was submitted to competent authority to find out whether it was possible to stretch its meaning, to twist it into something that would warrant the Government in either continuing embargoes, or doing something to make good to the chrome men and to these other men who had strained or impaired their financial resources on the good faith of the appeal from Washington; and it was found, no matter how hard the legal interpretation was strained, there was nothing in the War Minerals bill that gave any comfort, and that we would have to start all over again to prepare the mining industry for the problems of peace just as we had started before to prepare it for the business of war.

You will remember what Mr. Callbreath told you of the fight that had to be put up to get a modification of the Internal Revenue law with reference to the doctrine of depletion, so that individuals and mining companies paying dividends would not have their business wiped off the earth by taxes. If we had had a Cabinet officer of Mines and Mining, the manifest logic and equity of the miner's contention would have been understood from the beginning. The educational propaganda in its favor would have been given a place at the President's table, and we would not have had the situation that confronted us even when faithful subordinate bureaus of the Government took into hand so plain a proposition as the depletion of ore in a mine. We had to educate a committee in charge of a Revenue bill from the ground up. Why, the first suggestion of the doctrine of depletion in a mine was met almost as if it were the dream of a porch-climber; and I imagine that if the Bureau of Mines and the Geological Survey had not taken it in hand, it would not have had even a respectful hearing at the hands of the promoters of the bill.

Now let us look for a moment at the process of legislation at Washington. In the first place, the Interior Department cannot represent an industry like Mines and Mining. It is unfair to say that any man, unless he happened to be a man who was in the mining industry and was conducting mining operations before he became Secretary of the Interior, should have such detailed knowledge as would make him practically a Cabinet officer of Mines and Mining, though he were named a Secretary of the Interior. But put even an extraordinary man who was not a miner at the head of the Department of the Interior, and load him down with the Irrigation problems, the Reclamation problems, the Indians, Alaska, the disposition of the public domain, and all the other hundred and one problems, and you overwhelm him. Only a man like the present Secretary of the Interior can make any headway. When I think of the work that the Department of the Interior has on hand, it reminds me of the residuary clause at the end of a will: after you have given everything on earth that you think you own, or expect to own by the time you die, to everybody you care anything about, then you put in a drag-net clause at the end of the will. That seems to be the position of the Department of the Interior—the sump at the bottom of the shaft; something that is going to catch everything that any other department has left out. It is impossible to expect that this great industry is going to have the benefit of expert knowledge and proper consideration at the hands of an officer so loaded down as it would have at the hands of a special officer who is a mining man knowing all the dips, spurs, and angles of mining, and whose jurisdiction is confined to mining and the subjects affiliated with it.

Speaking of Congressional relief, I remember once a Congressman who was ready to take almost anything that constituent would give him in the shape of a matter of legislation. He did not stop to ascertain who was the sponsor of the bill. If he could do a favor, or if it appeared right, he would introduce it, let it go to print, and probably never examine it in critical detail until it came back from the printer. That is the attitude of many men when they first go to Congress. They soon learn to act differently. They learn not to land outside the breastworks. They aim to have their names identified with measures that have the backing of the Administration; and after they have been there a number of sessions they become the tamest house-cats you ever saw, and if you go to them with a bill, about the first thing they want to know is whether the particular department in the Cabinet, the department that would have charge of the bill or within whose scope it would be, has done anything or said anything in approval of the bill. Not only must you have, if you can get it, the benefit of the approval of the Department, but no bill will go through without the approval of the department; and once you get the approval of the department there is very little trouble with the bill except in the initial stages.

Under the process of legislation at Washington, there is no comparison between the authority that a Mining Bureau even, or a Geological Survey or any other kind of a survey, can give to a bill—a relief measure, for instance, such as we need right now—and that which would come from the approval of it given by a Cabinet officer who sits at the President's table. And if any controversy comes, under which the President himself might have some idea at variance with the bill, you have a Cabinet officer who can debate the matter with complete data and fair opportunity for such consideration or amendment as will gain his approval.

Mining men will find that henceforth mining is not going to be considered simply with reference to the geological conditions under which mineral can be produced, but from an entirely different aspect, namely, in its international aspect.

You are going to have not only the question of whether you can physically mine, as, for instance, whether you may or may not be allowed to dump something into a river, or any other little local question that may arise, but you are going to have on your hands the question of the production of minerals in the United States in its international aspect; you are going to have that all before you now when you take up the question of conducting mines and mining for the future. And it seems to me that no stronger case can be made than the experience that we have had in this war to demonstrate the utter inadequacy of our present instrumentalities to accomplish what we found we needed to do in a hurry at the beginning of the War and to grapple with the tremendous problems that are now coming before us after the War is over. What was needed then, and what is needed now, is a Cabinet Department of Mines and Mining.

Draining Air-Piping for Pneumatic Tools

*It is important to provide means for effectually separating and draining the water of condensation from the piping system of pneumatic tools.

The 'slugs' of water frequently coming through the pipes, in the general run of plants, not only interfere with the momentary operation of tools, but cut out the valves, cylinders, and wash out the oil, seriously interfering with lubrication. The water cannot be properly taken care of merely by placing drain-cocks at low points in the ordinary piping system, but should be removed by special separation tanks or chambers placed at these points, and near the distributing manifolds. The separators will also serve as collectors of scale and dirt coming through the pipes, and the drain or blow-out valves should be large enough to discharge these matters as well as the water.

The separating-chamber should be large enough to lower the velocity of the air to a point where entrained water or dirt will not be carried through with the air current, and should be fitted with bafflers or connections which will change the direction of flow, so as to precipitate the entrained matter.

While the arrangement of separators will necessarily be governed by the piping lay-out in each individual installation, the accompanying cuts, Fig. 1 and 2, illustrate two types, which in the smaller sizes can readily be made up of standard pipe fittings. Fig. 1 shows a type suitable for vertical risers, while Fig. 2 indicates a type suitable for horizontal distributing lines.

An air piping system should be uniformly graded with the direction of flow, so far as the main runs are concerned, and should always have separators at or near rising points. Sags or pockets without separators for the accumulation of water should never be permitted.

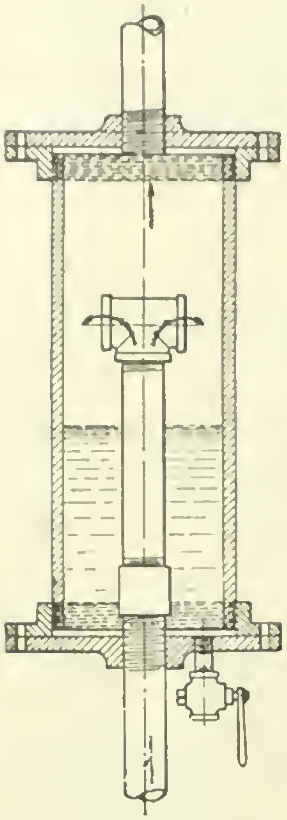


Fig. 1

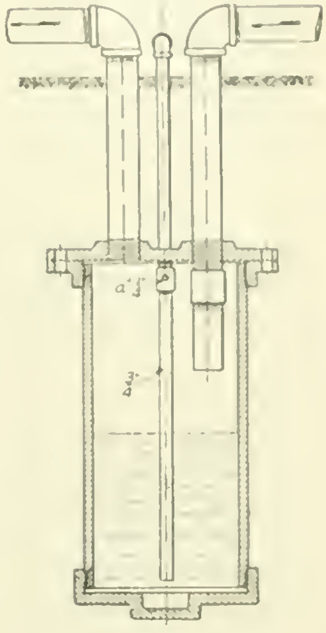

Fig. 2

Where it is possible to do so, separators on outdoor lines should be placed in the ground below the frost-line, to prevent freezing, as shown by Fig. 2. The condensation can be blown out through a vertical discharge pipe by the pressure of the air in the separator.

---

*'Standard Practice Bulletin', Emergency Fleet Corporation.

By-products of the silver ore mined at Cobalt, Ontario, during 1918 were 213,186 lb. of metallic nickel valued at $88,720, and 962,309 lb. of nickel oxide, carbonate, and sulphate valued at $215,277. The total nickel content was 736,005 lb., or 368 tons. The Sudbury district of Ontario produced 45,886 tons of nickel last year.

Manganese imports last year amounted to 491,303 tons, worth $15,095,867. Brazil supplied 345,877 tons and Cuba 82,974 tons. In 1917 the total amount was 629,972, and 576,321 tons in 1916.

Oil and products exported from the Tampico district, Mexico, to the United States during 1918 amounted to 39,618,121 barrels.

The Wolf Patent on Flotation

No. 787,814. Patented April 18, 1905.
United States Patent Office.
Jacob David Wolf, of London, England.
Separation of Metals from Their Ores.

Specification Forming Part of Letters Patent No. 787,814, Dated April 18, 1905. Application Filed May 22, 1903. Serial No. 158,346.

To all whom it may concern:

Be it known that I, Jacob David Wolf, a citizen of the United States, residing at London, England, have invented certain new and useful Improvements in the Separation of Metals from Their Ores, of which the following is a specification.

The present invention relates to improvements in obtaining metals from their ores, the object being to separate the valuable and metallic-mineral constituents of an ore from its gangue by the use of oil or grease, particularly oil or grease which has been treated with chlorid of sulfur.

According to this invention the ore-pulps are agitated with oil, preferably mineral oil mixed with viscous animal or vegetable oil and treated with chlorid of sulfur, until the oil has taken up all the metallic-mineral contents with some gangue. The mineral-bearing oil is separated from the pulps, and suspended particles of gangue are removed from the oil by passing it through warm water, the metallic minerals being thereafter separated out from the oil, which can be used again. At the same time oil is recovered from the waste pulps by blowing air through them.

In order to increase the viscosity of certain mineral oils, a small proportion—say five per cent.—of animal oil, such as lard-oil, may be added before sulfo-chlorinating. Vegetable oils—such as rape, castor, or linseed oil—act in a similar manner. With pulps having a large proportion of mineral, as in the case of copper, lead, or zinc ores, the prepared oil should be made thick and viscous to produce the necessary power of flotation; but with pulps in which the percentage of mineral is small, as with gold ores, the oil need not be thickened to the maximum extent. In the same way if the particles of mineral are coarse the oil should be specially viscous, while with fine particles the oil may be relatively thinner.

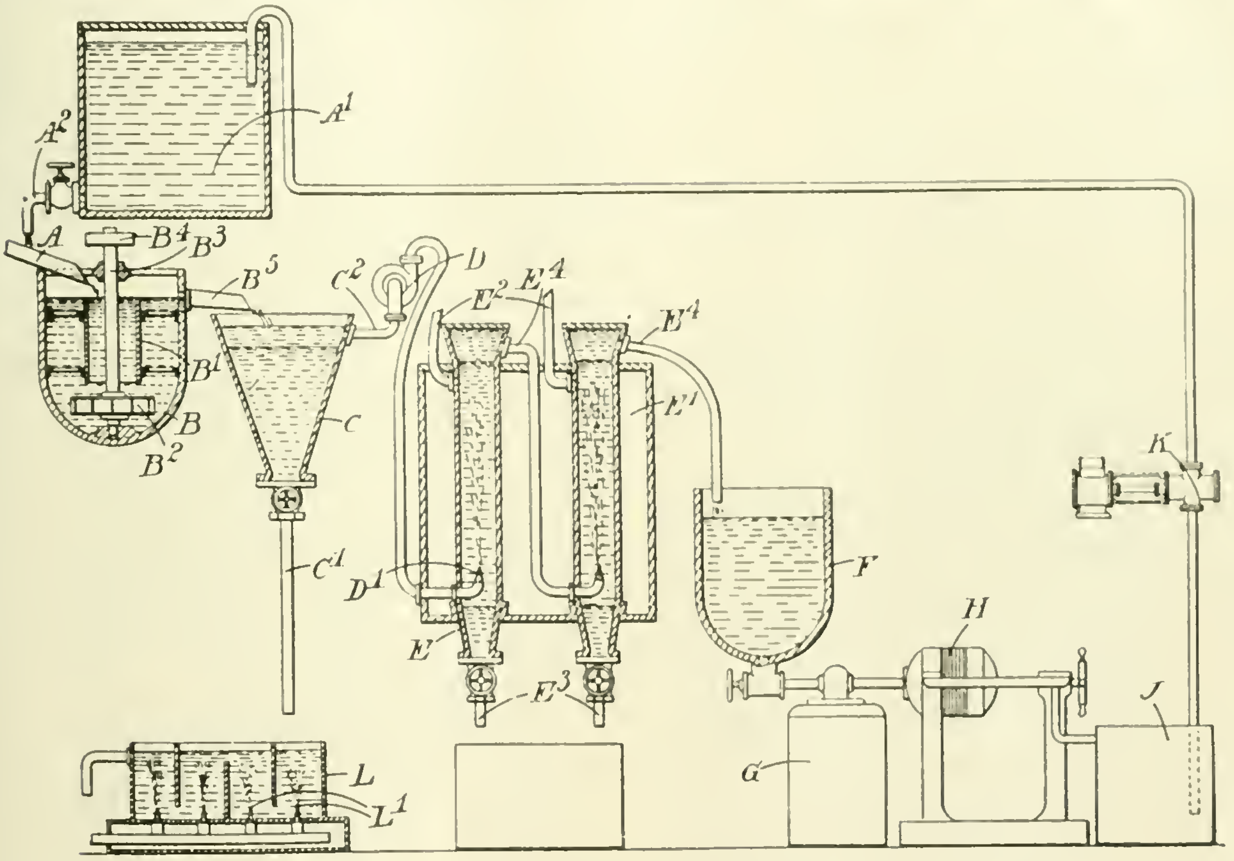
The accompanying drawing is a diagrammatic sectional view of apparatus suitable for use in carrying out this process.

In the following description it is assumed that the oil is treated with chlorid of sulfur; but it is to be understood that the same process and apparatus would apply to other suitable but untreated oils.

The ore mixed with water is crushed into a pulp and is introduced by a launder *A* into a mixer *B*, the oil, preferably treated with chlorid of sulfur, being simultaneously run in from the tank *A′* through the pipe A^2. The mixing vessel *B* has a vertical hollow cylinder *B′* fixed in the middle of it, and below the cylinder is a turbine-wheel B^2 on a vertical shaft B^3, rotatable through the pulley B^4. The mixture of oil and pulps passes into the hollow cylinder *B′*, and the rotation of the turbine-wheel B^2 causes a rapid circulation of the mixture downward within the cylinder and upward between the cylinder and the vessel *B*. The liquid is continuously discharged from the mixer through the pipe B^5 and passes into a separating-tank or spitzkasten *C*. Here the sulfo-chlorinated oil adhering to the mineral of the ore floats, while the gangue remaining in admixture with the water sinks and is removed by the waste-pipe *C′*. The mineral-bearing oil passes off from the surface through the conduit C^2. The mixture is next forced—for example, by means of a rotary pump *D*—in at the bottom of a vertical cylindrical vessel *E*, containing warm water and surrounded by a steam or hot-water jacket *E′*. The vessel is provided with a water-inlet pipe E^2 and a waste-outlet E^3 at the bottom, and an oil-outlet E^4 is also provided near the top of the vessel. The oil mixture carrying particles of gangue in suspension is passed into the vessel *E*, preferably through a perforated inlet *D′*, to break the oil into thin streams or globules, which rise through the warm water and drop out the gangue in their upward course on account of the decrease in viscosity. If desired, two or more of these vessels may be used in series, the mineral-bearing oil being removed from the surface of each vessel. By the means thus provided for eliminating gangue it is possible to treat ores with such a degree of agitation that the whole of the mineral contents are taken up by the oil, accompanied, however, by a not inconsiderable proportion of gangue; but as practically all this gangue is removable from the oil by a sufficient treatment with hot water much cleaner and sharper concentrates can be obtained than would be the case under any circumstances without such washing. The oil carrying practically only the values is next passed into a receiver *F*, from which it is forced, by means of a pneumatic forcing apparatus *G*, into a filter-press *H*, which may be of any suitable form—for example, of the type now largely used in the treatment of lard, tallow, and similar oils by fullers' earth. The separated oil is received in a tank *J* and is returned, by means of a pump *K*, to the oil-supply tank *A′* to be mixed with fresh quantities of pulps, the process being thus rendered cyclic. The properties of the oil are permanently altered by treatment with chlorid of sulfur; but it may be found advisable to add a further quantity of chlorid of sulfur after the oil has been in use for some time.

The waste pulps removed from the bottom of the settling-tank *C* are collected in a vessel *L*. After agitating the pulps with the oil-globules, which from various causes are not completely separated by flotation, but remain in the waste pulps, can be largely separated therefrom and recovered by blowing a current of air or air and steam through jets L' upward through the waste pulps. The oil-globules rise to the surface and break, forming a film which is not liable to sink again and can be recovered by skimming or by surface baffles or the like.

It is to be understood that the form of the apparatus used can be varied without departing from this invention. For example, when separating the suspended gangue from the oil any convenient means may be used for passing the oil through warm water, and in removing the oil from the waste pulps currents of air or steam may be produced in any way. Also any other suitable method separating the values from the oil may be adopted.



APPARATUS OF WOLF PATENT

What I claim as my invention, and desire to secure by Letters Patent, is—

1. The herein-described process of separating metals from their ores which consists in agitating pulps with oil until the oil has taken up all the metallic-mineral contents with some gangue, separating the mineral-bearing oil from the pulps, removing suspended particles of gangue from the oil by passing it through warm water and separating metallic minerals from the oil.

2. The herein-described process of separating metals from their ores which consists in agitating pulps with oil until the oil has taken up all the metallic-mineral contents with some gangue, separating the mineral-bearing oil from the pulps, removing suspended particles of gangue from the oil by passing it through warm water, separating metallic minerals from the oil which can be used again and recovering oil from the waste pulps by blowing air through them.

3. The herein-described process of separating metals from their ores which consists in agitating pulps with sulfo-chlorinated oil until the oil has taken up all the metallic-mineral contents with some gangue, separating the mineral-bearing oil from the pulps by flotation and removing suspended particles of gangue from the oil by passing the finely-divided oil upward through warm water.

4. The herein-described process of separating metals from their ores which consists in agitating pulps with sulfo-chlorinated oil until the oil has taken up all the metallic-mineral contents with some gangue, separating the mineral-bearing oil from the pulps by flotation, removing suspended particles of gangue from the oil by passing the finely-divided oil upward through warm water and filter-pressing the oil to separate out the metallic minerals from the oil.

5. The herein-described process of separating metals from their ores which consists in agitating pulps with mineral oil mixed with viscous oil and treated with chlorid of sulfur until the oil has taken up all the metallic-mineral contents with some gangue, separating the mineral-bearing oil from the pulps by flotation, removing suspended particles of gangue from the oil by passing it through warm water, and after that the metallic minerals are separated from the oil which can be used again.

6. The herein-described process of separating metals from their ores which consists in agitating pulps with mineral oil mixed with viscous oil and treated with chlorid of sulfur until the oil has taken up all the metallic-mineral contents with some gangue, separating the mineral-bearing oil from the pulps by flotation, removing suspended particles of gangue from the oil by passing the finely-divided oil upward through warm water, filter-pressing the oil to separate out the metallic minerals from the oil and removing oil-globules from the waste pulps by spraying jets of air and steam upward through the pulps and skimming off the oil which floats.

In testimony whereof I have signed my name to this specification in the presence of two subscribing witnesses.

Concentrating Graphite in New York

By GEORGE D. DUB

*Graphite mining in New York was started 60 years ago. That State, for many years, and until 1915, produced more graphite than any other, but since 1915 has had to relinquish first place to Alabama, where the growth has been remarkably rapid.

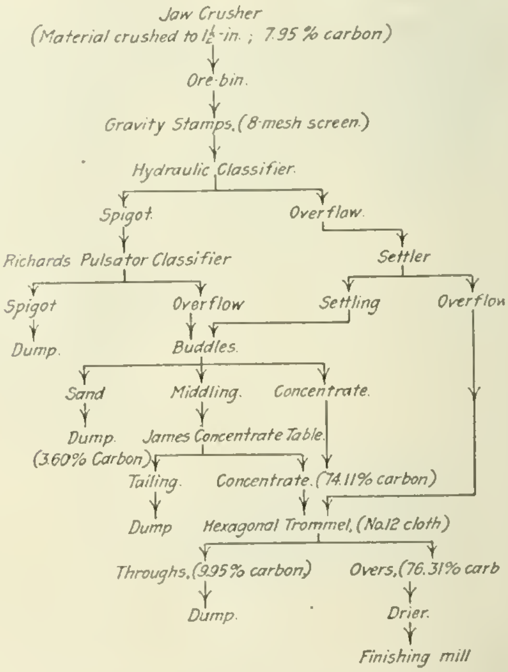
The ore in New York averages 4 to 6% graphitic carbon, compared with the 2½% ore of Alabama. There are two important types of graphite deposits in the Adirondack foothills of New York—first, those on the contact of a limestone and pegmatite; and, second, those on the contact of the Hague garnet-sillimanite gneiss and Faxon limestone or Swede-Pond gneiss. In the former occurrence, large flakes of graphite are obtained, but deposits of this nature are extremely pockety, and their development has not been profitable. Present production is obtained from the second type of deposit, in which the ore is nearly regular and of a more uniform grade. The ore is, as a whole, much harder and more silicious than that of Alabama, resembling in many respects the unweathered blue rock of Alabama, which is the original blue-colored Talladega schist.

At the present time, there are only three mines in operation, namely, the mine of the Graphite Products Corporation, three miles north of Saratoga Springs; Hooper brothers mine, four miles west of Whitehall; and the mine of the American Graphite Co., operated by the Joseph Dixon Crucible Co., four miles west of Hague.

Ore is mined in New York both in open pits and underground, the larger part from the latter system. Drilling in all cases is done with machines. Because of the silicious character of the ore, a greater quantity of fine is produced during crushing than is obtained in Alabama. The ore-bearing horizon is usually not over 25 ft. thick, and averages 15 ft. Wherever possible, the open-pit system is used, because of the ease and cheapness of preparing for mining, where there is no excessive amount of overburden requiring stripping. The deposits dip 25 to 35°, so that it soon becomes necessary to go under cover for the ore. This has its advantage in the north, because of the long and severe winters which hamper open-cut operations. The system of underground mining at the largest mine in the district is the room-and-pillar method, with underhand stoping. In new developments, a definite system of mining has not as yet been decided upon.

A flow-sheet of one of the plants in New York is given in the accompanying figure.

As indicated, gravity stamps are used as fine crushers, and 'buddles' as concentrating machines. It is also to be noted that concentrating tables are in use for treating 'buddle' middling, while in Alabama they are to be employed in raising the grade of rough concentrates preparatory to their treatment in the finishing mills.



FLOW-SHEET OF A NEW YORK GRAPHITE PLANT

With crude ore that analyzed 7.95% graphitic carbon, 'buddle' tailing analyzed 3.60% C. Tailing from various other machines carried 3.96 to 9.95% C, the latter product consisting of the fine through the rough concentrate trommel. The crude concentrate assayed 76.31%.

Refining methods do not differ greatly from methods employed in Alabama plants. One variation noted was the use of the Hooper air-jig instead of air classification. The chief disadvantage ascribed to the Hooper air-jig is its small capacity. The refinery operated by the American Graphite Co. at Ticonderoga is used in preparing graphite from many sources, foreign as well as domestic, and of both the amorphous and crystalline varieties, for use in the manufacture of commercial articles, such as paints, foundry-facings, pencils, lubricating flake, and boiler compounds.

*Abstract from U. S. Bureau of Mines War Minerals Investigation Series No. 3.

American Institute of Mining and Metallurgical Engineers

Speech of the President, H. V. WINCHELL

*I am told that it is customary on the recurrence of this annual event, for the incoming President to present for your consideration and that of the members at large a few thoughts as to the work of our Institute, and the industry which it is supposed to represent; to sound the keynote of progress for the coming year and to direct attention to the work of the hour.

If this be already a custom, it is something for which neither you nor I can be held responsible, and yet something which neither of us can escape. It is therefore my duty and high privilege to prepare the dose, and yours to take it as gracefully as possible, in the full belief that what is customary is proper, and what the doctor prescribes is beneficial, though not always palatable. In this case I trust it may be both.

It is a trite saying and a true one that we are living in the most wonderful period of history. We are witnessing the evolution of a new order of things. We are participants in movements which are everlasting in their effect and world wide in their scope. Forces and activities now set in motion will have their influence on the human race throughout its entire period of existence, and the lustrum of time of which 1919 is the closing year will be forever marked in red and gold on the pages of history.

It is entirely proper for us to reflect with pride upon the service which our Institute and its members have rendered the cause of humanity in the recent conflict. The names of those who have given their money, their time, their efforts, and in many cases, their lives, will ever be held in honored memory. But it is not sufficient to complacently remember the past. Our work is still ahead, and it is timely for us to consider our relation to our profession, to our country, and to ourselves in the working out of the problems of the future. What part are we able to play in reaping the benefit which should and must accrue from the sacrifices of the world since 1914? Is there any work which the engineer is better qualified than any other class to undertake? Is he now already preparing in true engineering fashion to get 100% efficiency out of himself and his organization? As educated and reasoning citizens of the world's greatest democracy, as trained engineers, as members of the American Institute of Mining and Metallurgical Engineers, what can we as individuals and as an organization do, what are we morally and in a sense of reciprocity obligated to do, under the new conditions with which we are confronted, to improve our own situation and that of all mankind?

The answer depends on the nature of the problem and the conditions with which it is surrounded. Do we fully realize the momentous changes which have already taken place? A nation which was taught by Washington to avoid foreign entanglements has in the interests of self-preservation been forced to take an active part in the settlement of a war in Europe, and is now occupying a prominent seat at the council of nations. Within a single twelve months we have abandoned the policy of our forefathers and become an arbiter and co-administrator of the affairs of all countries. Never again can we pretend to stand aloof and unconcerned while war flames are kindled abroad. No longer can we afford to be provincial. The ocean now is narrower than was the English Channel before the construction of telegraph lines, steamships, submarines, and airplanes. The food supplies, the raw materials, the factories, the mines, the schools, the people of foreign lands are now subjects for our careful study and consideration. We are and shall be impelled to it by motives of every variety, materialistic and humanitarian. The better we understand the world and its problems, the more successful we shall be in our commerce, in the development and handling of our internal affairs, our finances and our labor questions, our crops, our mineral production; everything that concerns our prosperity and welfare.

Then, too, from a nation of borrowers, needing foreign capital to develop our resources and owing vast sums upon which we were paying interest to the bankers of Europe, we have suddenly by fortune of war become a creditor nation. The nations of the world owe us inconceivable sums. The interest on our loans abroad would have paid the entire expense of our national government when we men were youths. This change in our status is of tremendous importance to the engineer, whose field of operations has thus suddenly become widely extended. The first and immediate demand for engineering talent probably lies in connection with the problems of restoration and reconstruction in the devastated areas. To what extent American engineers will be used in this work depends largely upon the supply of materials of construction and of engineers in Europe and upon the ability of our trans-Atlantic neighbors to finance their operations without our aid. In many districts, mines and manufacturing plants have been destroyed; in others, worn out; in most cases on the Continent, production has been pushed to the maximum without stop-

---

*A speech made at the banquet in New York on February 20.

ping for repairs; railroads and highways have been worn unceasingly, and must need renewing. And in addition to this plant and material exhaustion, it must be remembered that there has been appalling loss of life among the engineers and those of sufficient mentality to make army officers. Increased and intensified demand for materials and a shortage of designing and constructing engineers would seem to create unprecedented opportunities for this country of matchless resources in both. And here is where the advantage of the United States as an opulent and creditor nation becomes doubly accentuated. Now for the first time in our history we have more money than we can spend at home; now the wide world is our field of operations; now we are compelled to search for development enterprises in which our surplus capital may be employed; now we must, in spite of ourselves, become cosmopolitan. And since those very countries which are our debtors are the ones which most need our assistance, it is only by increasing our business with them and our investments there that those debts will ever be paid. By enabling them to re-build, by establishing them again on a prosperous basis we shall at the same time protect the investments and loans already made under the necessities of war. Does this situation not promise work and opportunity for the engineer?

But the War has brought other changes. The employment of man power and materials for the sole purpose of destruction has been so general and widespread as to change living conditions over a large portion of the inhabited globe. Economic laws have been arbitrarily set aside, and the governments have been compelled to establish artificial prices and regulations for the transportation and allocation of labor and materials. The inevitable result has been dissatisfaction, uncertainty, and confusion. The workman who has recently been receiving fifty dollars per week instead of the former twenty-five cannot understand why there should be any reduction now that the War is over. The farmer still wants war price for wheat; the Southern planter wants war price for cotton; and the field hand still desires to work half time and get double wages. On the other hand there is a general desire for a reduction of the cost of the every-day necessities of life. In short, we are faced with a condition of unrest and uncertainty in all quarters of the globe. Every thoughtful person knows that there must be readjustment, but no one can foresee its precise trend and effect. Is there not here again a demand for the influence and effort of the intelligent engineer?

Those of us who have watched the spread of Marxian socialism abroad, who have seen its adoption by the Russian Bolsheviki and have seen their poisonous propaganda insidiously inoculating the workingmen of Russia, Austria, Germany, and even England, and who have read the anarchistic publications of their disciples in this country cannot but feel that it is high time something was done to counteract it. Bolshevism is the antithesis of democracy; it is the foe of freedom; it is a rule by a class, and that class the most ignorant and least civilized in the community. It matters not whether it be found in the parlor or in the revolutionary parade, in the poisoned press or on the street platform, bolshevism is an abomination subversive of order and government, and must be opposed by every patriot and loyal citizen, by every influence and power which desires the welfare of mankind.

It has often seemed to me that the engineer is not fully awake to his duties and privileges as a citizen; that he is too engrossed with the details and the mechanism of his profession; that his mind dwells too much on facts and figures and processes; that he is too retiring by training and disposition, too little of a publicist and a humanitarian, and too much of a materialist. I believe that individually and through his organizations he should take an active part in every movement that concerns the good of society; that he should take the initiative in shaping the policies of government; that he should be an aggressive educating and moral force in every community.

On his visit to this country in 1876, at the founding of the Johns Hopkins University at Baltimore, Thomas Huxley addressed us as follows: "Truly America has a great future before her—great in toil, in care and in responsibility, great in true glory if she be guided in wisdom and righteousness, great in shame if she fail. I cannot understand why other nations should envy you or be blind to the fact that it is for the highest interest of mankind that you should succeed; but the one condition of success, your sole safeguard, is the moral and intellectual clearness of the individual citizen."

In all branches of business, in all lines of human endeavor, we have been taught to strive for efficiency. Indeed, so greatly has the idea been stressed that we have been in danger of regarding it as the end in itself. We have forgotten why we are thus striving. We have often had our attention directed to the efficiency of the German people as something well worth imitating. Dr. Nicholas Murray Butler, in a most scholarly address on 'Education after the War,'[1] has given us a timely warning: "The War has taught the lesson that the proper place of efficiency is as the servant of a moral ideal, and that efficiency apart from a moral ideal is an evil and a wicked instrument which in the end can accomplish only disaster. In other words, we should encourage efficiency not for its material results, not simply for the greater amount of wealth in dollars and cents, in bushels of wheat, tons of ore or yards of cloth thereby produced, but for its value in the development of character, and for its aid in the achievement of our ideals and the guidance of the individual and the race in their progress toward fuller self-expression and more complete self-realization."

Now, the only road to efficiency is education. In all departments of life, in business, in government, in commerce and trade, education must precede efficiency, and the broader and more widely disseminated the real education of a people, of a class, of a community, the higher its efficiency. And this brings me down to the suggestions which I wish to make this evening.

---

[1] 'Educational Review', January 1919.

Scarcely a day passes that the newspapers do not contain notices of strikes, of lock-outs, of labor dissatisfaction and disturbances in this or that industry. The strife between the employer and the laboring man is incessant and irritating to both. It is world-wide and apparently everlasting and its cost is beyond calculation. It has received the careful consideration of the world's greatest economists, and is a problem whose solution requires far greater intellect than mine. Nevertheless, it vitally affects the interests of every one of us here tonight, for it contains possibilities which one shudders to contemplate, with the tide of Bolshevism rolling westward, and other forces at work to mold our civilization into new and different and untried forms. Here and now are demanded more than ever before that "moral and intellectual clearness of the individual citizen" referred to by Huxley; now, more than at any period in our history do we appreciate the worth of that poise and stability which are provided and acquired by education; and now do we feel more fully than ever the importance of extending education to those of all classes who are in any way responsible for the industrial turmoil existing and impending.

It has always seemed to me that labor troubles must, in large measure, result from a failure on the part of the protagonists to understand each other's respective situations and motives; from a lack of comprehension of the simple elements of economics on the part of the masses, and the failure on the part of the employer to explain how and why conditions have arisen which have made necessary or inadvisable a readjustment of any accepted or demanded situation. In other words, through lack of education. And here, it seems to me, is an opportunity and a duty for the engineer. He occupies a peculiar relation to the capitalist and the laborer. He is customarily one of the employed; he is, on the other hand, the adviser and trusted representative of capital. He comes into frequent and close contact with the laborer, and is in a position to understand his difficulties, to win his friendship and confidence, and to impart advice and information which would go far to explain the difficulties of any given situation. He is a sort of middle-man, who might easily acquire such influence with those above and below him as to be of very great aid in time of industrial crises. If this be indeed true, then it must follow that in not exercising his privilege, in not performing this service, he is not meeting fully his responsibilities as an engineer and a citizen. As the boys would say: he is not strictly "on his job."

Let us consider for a moment the situation in the average mining camp. A few hundred or a few thousand miners are employed. Here they come, muckers, mule skinners, trammers, nippers, timbermen, machine men, track layers, powder monkeys, station tenders, pipe men, carpenters, electricians, shift bosses, blacksmiths, and helpers, of different nationalities and varying degrees of intelligence and education. They are checked in and checked off by the time keeper; except in case of accident they spend their allotted time on the job and disperse without receiving as much personal attention as the mules underground. When not at work, they spend their time idling around saloons or other shady resorts where they not only learn nothing to their advantage, but spend their substance and sap the foundations of their health and strength, mentally, morally, and physically. Under such conditions they afford fertile and receptive soil for the seeds sown by the demagogic agitator. They attend open or secret meetings of the union and are constantly taught the program of violence and disrespect for law and order. In those camps where club houses are provided and reading matter and forms of amusement furnished, they are seldom visited and cultivated by anyone connected with the mine management. The men are still left to their own devices, and no advantage is taken of the opportunity to gain the friendship and confidence of those who are approachable, to aid those who are worthy and in need of some sort of encouragement or assistance, or to educate those eager for knowledge.

In recent years, it is true, many mining companies have arranged for moving-picture shows two or three times each week; in some States like Nevada, the State educational institutions, such as the College of Mines, have of late years conducted night schools for instruction in scientific and technical subjects; and the Federal Bureau of Mines has sent its car around and taught the men the principles and methods of safety first. In all of these matters, the mining engineers have taken a part and shown sympathetic interest; but it seems to me we have fallen far short of the full measure of our duty and our opportunity. We have failed on the social and humanitarian side; we have done little to counteract the deliberate spread of socialistic and bolshevistic doctrines; we have permitted the raising of a crop of noxious weeds on soil which might well have yielded the fruits of thrift, industry, loyalty, and patriotism.

With the coming of prohibition and the closing of the saloons, those old-time haunts of the miner, we find the men increasingly in need of comfortable recreation quarters, and in better condition to be interested in opportunities for entertainment which shall be at the same time instructive and uplifting. There are many forms of such entertainment, and many methods by which such instruction may be given without the appearance of officiousness or pedantry. I have never yet visited a mining camp where there were not some men of ideas, of travel, of wide experience and observation, of talent in some form of entertaining, where there are not frequent visitors who could be pressed into service for the benefit of the general cause of education and good fellowship. And there are ways and means by which such service could be organized and carried forward. There are national organizations and societies; there are State institutions; there are our own Local Sections; and there are the mining companies themselves which would quickly appreciate the value of such work among their men. It is probable that our Committee on Industrial Organization, with its sub-committee on Education, may be already at work along these lines. But we should not leave it entirely to small committees. It is work for every one of us, to be performed daily and perpetually, wherever we may be. It is not only a moral duty, but is one of the best expedients for making sure of permanent tenure of our positions and the salaries thereto attached. How many of our engineers are now enjoying princely honorariums in Russia? None. How many are at work in Mexico? Very few. What is the fundamental reason in both countries? Illiteracy. How many engineers will be thrown out of employment if bolshevism carries out its declared program in the United States? Untold thousands. Is it not then, in the most literal sense, our job to protect our jobs by dissolving and dispersing the clouds of prejudice and ignorance which threaten the existence of all kinds of employment and the destruction of all industry? Yea, verily.

Nor is the laboring man the only one who needs educating. We need it ourselves; and so do Congress and capitalists, managers, and the general public. The engineer's own education is too often defective in economics and politics, and he suffers thereby. He is wounded in his most sensitive parts by bad mining laws, by wrong principles of taxation, by ill-advised governmental regulation. In the conduct of all these matters he often has a keen sense of defective functioning, but is not sure of the remedy, nor skillful and earnest in urging its adoption; and in his perplexity often decides that he is not the doctor nor the plumber to stop up that particular leak! And when the trouble has grown irritating and chronic and no one provides a cure he is apt to become cynical and to blame society and the government for a situation which he himself should have helped to alleviate.

Now, Brother Engineers, let us have more confidence in the essential fair-mindedness of our fellows; let us believe in the future of our country; let us feel some responsibility for the condition of society; let us individually and through our Institute and kindred organizations cultivate simplicity of analysis, clearness of thought, expression in words of one syllable, and let us seek means by which we may increase our moral efficiency, improve the relations between the citizen and the Government, between the employer and the employed; and so add to the sum of human happiness. The task may appear great, but there are many workers, and there will be an abundant reward in the resultant and well justified consciousness of service rendered, combined with a swelling sense of pride of profession, pride of race, and pride of country.

Cyanide (sodium) imported into the United States during 1918 amounted to 69,279 lb., valued at $12,615, compared with 1,604,117 lb. and $803,604 in 1917, and 483,811 lb. and $102,663 in 1916. The potash salt imported was 141,808 lb., valued at $47,460, against 104,316 lb. and $76,303 in 1917, and 2705 lb. and $803 in 1916. These figures show that the supply of cyanide for this country is mainly from domestic sources.

Tungsten imports in 1918 totaled 10,362 tons, valued at $11,409,237. In 1917 the quantity was 4357 tons and value $4,467,608.

Helium and Oxygen

Investigations by the Metallurgical Division of the Bureau of Mines will, if successful, result in a real revolution in the fundamental industries of the country, according to Frederick G. Cottrell. He says: "When, at the suggestion of Sir William Ramsay, the British Admiralty first studied the possible use of helium for balloon purposes they felt that the expense of production would be prohibitive, first, on account of the great scarcity of the element and the very great dilution in which it was found in the atmosphere (1 vol. in 250,000) and in other gases, and, second, because of the expense of the processes of separation then known to the Admiralty. When this information came to the Bureau of Mines it was remembered that some of the natural gases of Kansas has been found by H. P. Cady, of the University of Kansas, to have over 1% of helium in them. The separation of helium from these gases could best be accomplished by the same general processes of liquefaction and distillation as are used to separate air into its nitrogen and oxygen for industrial purposes. It so happened that the Metallurgical Division of the Bureau of Mines had been making a study of these processes in the hope of finding a way to sufficiently cheapen the production of oxygen from the air to allow its general use in metallurgical furnaces and other large-scale chemical and industrial operations. If this were possible it would work a revolution in these fundamental industries. Take, for instance, the smelting industry alone. We now concentrate everything that goes into the furnace such as coke, ore, and fluxes, but not the oxygen of the air. This we add with four times its volume of inert nitrogen and thus undo much of the effect of the concentration of the other constituents. If we could use pure oxygen, or more concentrated air, a great saving could be effected, and we could do in combustion furnaces much that is now possible only in the electric furnace. One of the processes which the Bureau felt had much promise in this direction had not, up to that time, received any large development, but these facts were called to the attention of the Departments of the Army and Navy. They immediately appropriated jointly $100,000, and further sums afterward, now aggregating over $1,000,000, for trying the project. The plants using the older processes are already producing helium in large quantities, and the new one, on what it is hoped may prove much the more economic basis, is about to have a practical test in production. If it fulfill anticipations, its significance is much wider than the production of helium, for it will open the possibility of obtaining oxygen in quantities and at costs undreamed of by chemists and metallurgists hitherto."

Metal production of Italy for 1917 has just been published. The principal items of interest to Americans were 5789 tons of antimony, 38,076 tons of lead, 31,500 flasks of quicksilver, and 230,074 tons of sulphur.

Boiler settings for dredges, on which steam is used for power, should be as compact and light as possible.

Ventilation Methods in Coeur d'Alene Mines

By ROBERT N. BELL

*The metal mines of this State are mostly in high mountain regions. Those of the Coeur d'Alene have their vein outcrops on the mountain sides, and are developed by adit or cross-cut tunnels to depths varying down to over 2000 ft. This gives ample natural gravity air-pressure circulation that usually affords good ventilation and is easily controlled. The natural advantages of this region in this respect and its deep sedimentary formations are exceptional, but in recent years, in three particular cases, the ore penetration has been developed extensively below the lowest points of surface-drainage entry, involving cross-cut tunnels, three of which are two miles long. In these cases the tunnels are of a minimum size of 7 by 8 ft., and are used for drainage, haulage, and ventilation. They are costly openings to drive, and owing to the uncertainty of results to be found a double-entry tunnel was never warranted as it is in coal mine development, and the further fact that return outlets are invariably provided at high elevations for air circulation.

Above these deep drainage-levels, ventilation by natural gravity air-currents was a simple matter; but each of these mines, and several others in lesser degree, have shown persistence in their orebodies to great depth below these lowest drainage-entries, and the sub-levels thus developed have rapidly expanded in the past few years. This involves a new problem in ventilation, where the long tunnel is depended upon for the main air supply, by reason of the fact that the long electric ore-trains running in these air-courses act as a part piston and resistance when in motion against the air, and materially retard its flow. Sub-level ventilation by natural gravity air, even with these deep drainage advantages and numerous higher outlets, has lately proved inadequate in volume and velocity to fully supply the normal working requirements of the men, and must be assisted by mechanical means. A ventilating system that will simply carry away the smoke and gases from blasting and emanations from men and lights, is a mistaken economy in big mine operation, as the great harm resulting from an insufficient supply of good air is markedly shown in the behavior of the men employed in such a mine. Surliness, discontent, inefficiency, and a general desire to cut work or taper are often directly traceable to poor air, and there is no investment that will pay a bigger return in resulting efficiency of the workers than good ventilation.

The long tunnels of the Morning and Bunker Hill & Sullivan mines, due to the natural wall resistance and moving trains, are incapable of carrying sufficient air to properly ventilate their extensive and rapidly deepening sub-levels without mechanical induction. Fortunately, both have several other outlets in addition to their long tunnels which, while at a much higher level, can be used and are used as additional sources of fresh air, with the return or up-cast directed through still other outlets. These matters have been under discussion for the past four years with the State Mines Department, and the managements of these mines have been entirely willing and anxious to improve their ventilating conditions. To do so, however, in addition to mechanical installations, it involves the driving of several thousand feet of expensive straight-line raise connections, but as labor has been so scarce this work has been decidedly retarded.

In this connection, as men have been available, over 900 ft. of big raises have been driven at the west end of the Bunker Hill mine and are now being extended, to be used exclusively as an air-course, and during my visit to the property in December, a large station was being cut for a recently ordered 60,000-cu. ft. Sirocco fan. This is to take fresh air not only from the Kellogg tunnel, but also from the adjacent Sweeney shaft and other west end outlets, affording an ample supply for all purposes, when mechanically driven and controlled, to the deepest point of the mine within the necessary air-doors and stoppings. Present plans contemplate, if it is found necessary, the installation of another large Sirocco fan near the head of the No. 2 East shaft, which is a natural up-cast, and will afford a permanent circuit through the East end outlets, above the Kellogg tunnel. This is the deepest mine in actual ground penetration in the plane of the vein in the Coeur d'Alene. Its orebodies are entirely in quartzite formation. They vary in size up to 100 ft. in horizontal cross-section and 900 ft. in length. The mined spaces are uniformly timbered with square-sets and closely filled with waste. The levels are 200 ft. apart vertically and 300 ft. on the dip of the vein, which is 40°. The hottest place in the mine is 1500 ft. above the bottom level at the apex of the Cameron stope at the No. 10 level cross-cut connection. This is one of the largest stopes in the mine that has been actively operated for the past 12 years. At this point the temperature is 80°. The humidity reaches dew-point, and is largely due to local faulting, the friction of slowly packing fill, oxidizing timbers of the big stope, and the fact that it is a converging point of return air.

The highest bottom level temperature in the mine at the new 15th level, which is 4800 ft. on the dip of the vein below its highest crest, and 3400 ft. vertically under the mountain, registered only 70 F. This point is 5400 ft. in the pitch of the main ore-channel below discovery

---

*Abstract from report of State Inspector of Mines for 1918.

cut. The top of the big stopes at No. 13 and 14 levels registered 75°, and the No. 2 shaft-station main return air-course at the 13th level, 70°.

These are comparatively low temperatures for such depths. The mine, however, is damp throughout and the relative humidity is high in all these sub-levels, causing men to perspire freely at work, this giving the impression of much higher temperatures than actually prevails. The only remedy for this humid condition is a greater volume and velocity of fresh air-currents, and the company is making an earnest effort to attain this improved condition, which, I think, will shortly be accomplished.

At the Hercules mine, with a drainage cross-cut tunnel at its lowest point from Canyon creek only a few hundred feet short of two miles in length, the natural ventilation in its new sub-levels is still good. Its new vertical four-compartment shaft from this level is 1400 ft. deep, but only three sub-levels have yet been opened down to the 600-ft. level. The large underground hoisting-stations are completely sealed with tight air-doors. The main shaft in the winter carried 30,000 cu. ft. of fresh air in December, affording ample ventilation for the present levels, by way of the shaft, drifts, stopes, and up-cast through several large rock raises to the No. 4 tunnel outlet, 600 ft. above No. 5, a natural return-circuit in the summer. Stations are now being cut in the new shaft at the 800 and 1000-ft. sub-levels in this mine, where the natural temperatures are slightly under 70° and well ventilated by an exhaust-fan at the 600-ft. station.

The Hecla mine has a natural advantage in ventilation from the fact that its main working shaft starts at the surface, and does not involve the long adit approaches of the other mines mentioned. It is ideally situated for natural gravity-air ventilation, and the management has taken full advantage of this condition. This mine has a drainage-level on the course of its ore-zone several thousand feet, striking directly into the east side of the abrupt slope of Canyon creek, near the main surface shaft-collar. The main shaft now has a maximum depth to its new bottom station of 2000 ft. vertical. The bottom working-level is at 1600 ft., and the lineal distribution of the orebodies are strung out through fully 3000 ft., and duplicated with several parallel shoots of ore with many raises, chutes, and manways at short intervals.

Near the east end of the ore development an expensive straight-line raise, nearly vertical and 1400 ft. high, was put through to the surface from the drainage-tunnel for ventilation purposes. It gives a maximum gravity vertical range to the 1600-ft. level through connecting raises for natural air pressure of 3000 ft., with several other outlets above the drainage-tunnel to relieve the main west stopes. This theoretically presents almost ideal conditions for natural-gravity air circulation.

The main shaft has a large-size idle compartment, and each station drift-entry is provided with an air-door. In December this shaft, acting as a natural down-cast, was distributing 28,000 cu. ft. of fresh air per minute at high velocity through the lower levels, with return through numerous outlets to the surface. The recent rapid expansion and duplication of the operating openings and ore-shoots of this mine, all heavily timbered, develops a heavy resistance to free air circulation, in spite of its extremely high chimney-draft value. It also retards the flow of the return air, which is believed to be due, in part, to lack of proper splits in the west orebody, a condition that the company's engineers are now studying carefully with a view to remedy by additional doors and stoppings. If this is not effective, a powerful Sirocco fan will be put in as an exhaust, probably at the head of the No. 3 tunnel, 1400-ft. raise.

The temperature at the new 2000-ft. station in this mine in December was 70°, with relatively high humidity. Like all the other sub-level mines, the maximum or warmest place tested in this one, due to the same cause of temperature localization as the Bunker Hill & Sullivan and Morning mines, was at the top of an exhausted stope on the 600-ft. level, 1000 ft. above the bottom working-level, which gave a reading of 70°.

It would seem from the foregoing that the temperatures in the deepest mines of the Coeur d'Alene district are comparatively low, and range around ordinary normal summer heat at the surface. There prevails, as previously stated, however, a general dampness of the ground, with the resulting humidity or moisture in the air.

At the Bunker Hill & Sullivan mine, the stoping is all done on day shift; at the other mines most of it is done on day shift, and when two shifts are working in the stopes, the blasting is practically all done at the end of the second shift, which permits 8 to 16 hours' time for the mines to clear of smoke and gas from the blasts. Exhaust-fans are invariably used in dead-ends, and there is no point in the district where the air can be called bad at this time. In several of the properties, at the end of a shift with a big crew of men, it is poor, and can be greatly improved by mechanical means and new connections designed to facilitate the distribution of the currents. I look for a big improvement in these conditions during the coming year [1919] in all these deep mines, and an ultimate full solution of the problems involved, as is possible.

Aside from these growing ventilation problems, all of the great mines of the Coeur d'Alene are otherwise in good physical condition.

* * *

Wolfram production of Bolivia in 1917 (the latest figures) totaled 3828 tons of 60% concentrate. This was an increase of 842 tons over 1916, which in turn was 2207 tons greater than the 1915 return.

* * *

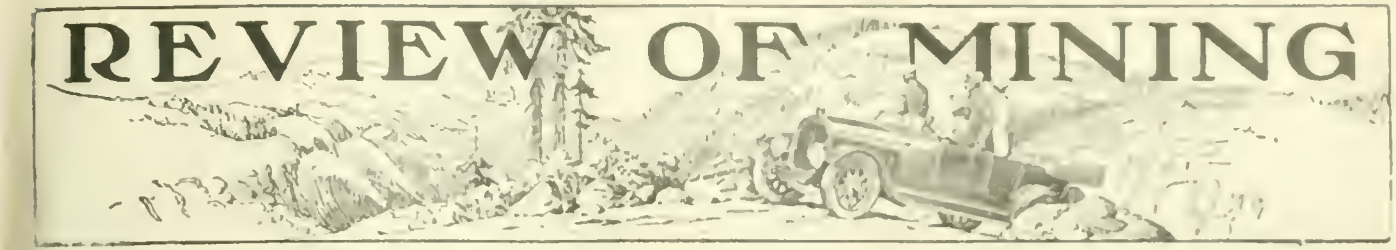
Chromite imports last year totaled 100,142 tons, valued at $2,891,725, against 72,063 tons and $1,098,659 in 1917, and 115,886 tons and $1,548,402 in 1916.

* * *

Graphite ore milled in Canada during 1918 amounted to 19,614 tons, averaging 8.6% graphitic carbon.

* * *

Manganese in steel averages 14 lb. per ton.

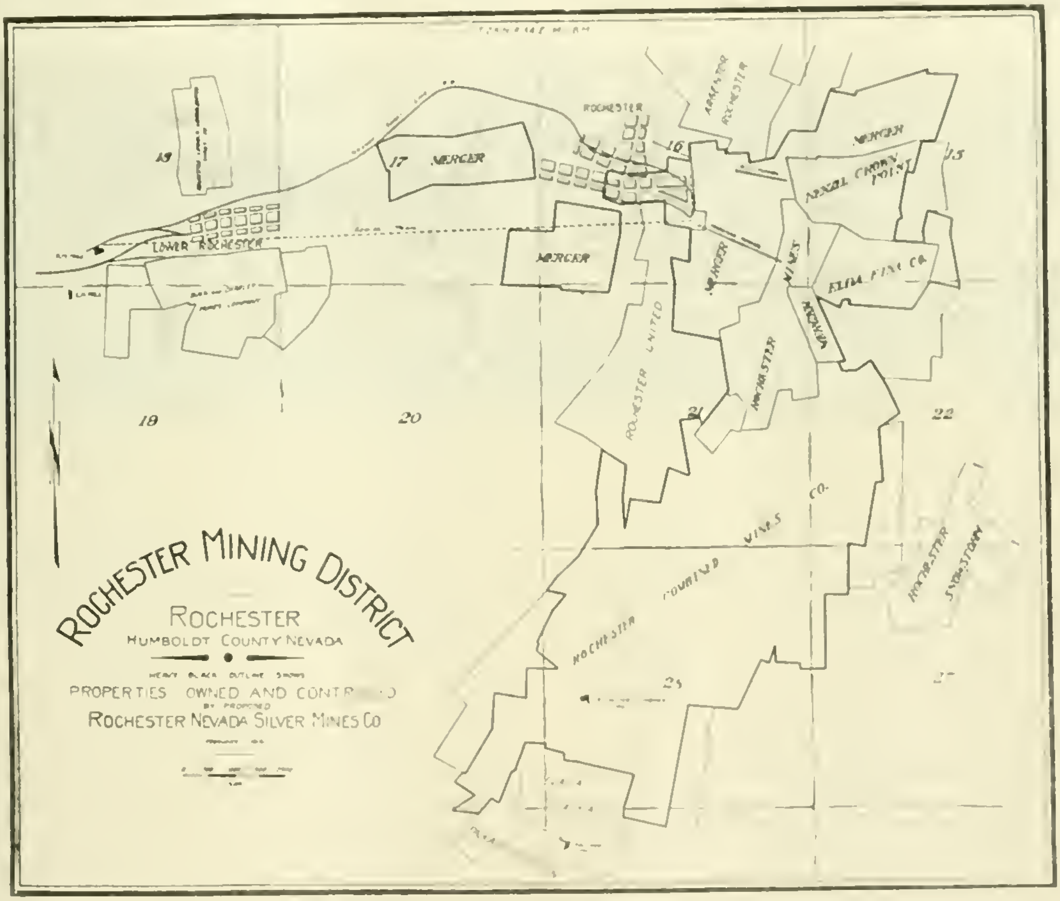


REVIEW OF MINING

ROCHESTER, NEVADA

The New Arrangements in This Field.

Organization of the Rochester Nevada Silver Mines Co. will be perfected shortly, upon deposit in the Reno National Bank of a majority of stock in the constituent corporations. Under terms of the agreement brought about by F. M. Manson, executive head of the Western Ore Purchasing Co., the bank will issue certificates of exchange for shares of the new holding company, but this stock is to remain in pool, in possession of the bank, until all indebtedness for the various companies is paid, but not longer than for one year from April 1, 1919. A board of trustees, composed of Mr. Manson, Judge L. N. French, and Jay H. Clemons, will select the directorate of the holding company. Attachments against the property of the Rochester Mines Co. have been released, and that company is again operating its mine and mill. Apex-rights were claimed by the Rochester Elda Fina and Rochester Merger Mines companies involving the principal vein system worked by the Rochester Mines Co. Voluminous reports were prepared in behalf of the apex claimants by O. H. Hershey, H. V. Winchell, Fred Searls, and other engineers and geologists. It was contended that the east vein, mined extensively in Rochester Mines territory, had its apex on the east side of the ridge that trends through those claims of the Elda Fina, Merger, and Nenzel Crown Point adjoining the Rochester Mines on the east, and penetrated by the Friedman and Pitt tunnels. A large amount of development work has been done in this area, and connection has been made from the Rochester tunnel workings with a tunnel debouching east of the ridge. All mine workings excepting the deepest in the Rochester Mines property are in oxidized material, and the geologists agree that there is good promise in the sulphide zone, particularly in the western area, where the veins dip into the Merger ground adjoining the Rochester Mines on the west, toward the town of Rochester. The Rochester Combined mill, with a capacity of 400 tons, is nearly new, and it is proposed to haul ore for this mill from the Merger and Crown Point properties, probably extending the tramway along the east side of the ridge. The Combined property has little ore of commercial grade, and its large area is so lightly regarded that it is referred to by one engineer as "a desert goat ranch." The other properties are regarded as valuable mines, and all have considerable quantities of ore available for milling. The Rochester mill is in good condition and has treated over 200 tons daily. It is now indicated that the new directorate and management will include few, if any, of the men formerly in control of these properties.



The Nevada Packard continues operating at full capacity

DIVIDE, NEVADA

What is Being Done in the Divide District.

At least 50 shafts are being sunk at Divide, formerly known as the Tonopah Gold Mountain district, six miles south of here, on the main road to Goldfield New companies are being formed almost daily and the district is staked for an area many miles in extent, new locations covering both the north and south slopes of Gold mountain.

In the Tonopah Divide mine the south cross-cut from the shaft has been extended to cut the main silver vein on the 465-ft. level. With the aid of an auxiliary hoist the shaft has been sunk 50 ft. below the fourth level, and stations will be cut at 100-ft. intervals. Water-level is estimated to be at 700 ft. When water is developed in the mine a mill is to be built. A contract just signed provides for treatment by the MacNamara mill at Tonopah of a maximum of 60 tons and minimum of 40 tons of ore daily from the Divide mine. The mill has been equipped with additional shallow settling-vats and a Dorr thickener. The Divide ore requires greater settling capacity than Tonopah ore, and the additions will permit the MacNamara company to treat its own ore. The main south-east drift on the third level has been advanced to the 350-ft. point from the shaft cross-cut, and from this point cross-cuts are being driven both ways in good ore. At the 300-ft. point the cross-cuts advanced 40 ft. each way; that to the north-east for the greater part in low-grade material. The ore-shoot is now opened for a length of 430 ft. on the third level. Raises from the second and third levels are nearing the drifts above.

On the 500-ft. level of the Brougher Divide the cross-cut, 75 ft. from the shaft, exposed a two-foot seam of ore assaying $18.85. About 15 ft. farther it passed through a seam of ore assaying $80 per ton. These seams dip from the vein, and were not found in development work on the 177-ft. level.

The Divide Consolidated, adjoining the Brougher on the north-west and said to have the Divide vein, has one of the best surface plants in that region. Vein formation exposed in starting the shaft assayed $9 over its width. The vein has been exposed by open-cuts, yielding assays from $2 to $104 per ton

The Tonopah Dividend, working on the 300-ft. level, has exposed kaolin in a crushed zone in its main vein, with a small amount of horn-silver. This material resembles the Divide high grade.

The East Divide shaft entered the lower breccia at 300 ft., and will be continued to 400 ft. for cross-cutting.

The Gold Zone has prospected its vein, apparently the Divide lode, up to the latter's boundary, and at this point found two feet of $20 ore. Cross-cuts are being driven to prospect for parallel veins, and a drift is being driven south-east on the 500-ft. level. F. Sommer Schmidt has been made director and consulting engineer of the Gold Zone, which is now said to be controlled by L. E. Whicher of New York and associates.

Divide Extension has the hoisting plant formerly on the Manhattan Morning Glory, and is sinking from the 150-ft. level.

The Sutherland Divide, north of the Tonopah Divide, has a good plant in place at its 400-ft. incline shaft, which will be sunk further 200 ft. while drifts are extended on the 400-ft. level.

The Alto Divide, adjoining the Gold Zone and East Divide, has started its shaft.

The Gold Wedge Divide, Rosetta Divide, Gold Seam, and several others are situated some distance south-east of the Divide mine, on the south slope of the mountain.

The Hasbrouck, farther west, is a relatively old property, having shipped a considerable quantity of ore several years ago. It is working in a 400-ft. shaft and 900-ft. tunnel, and in the latter has developed 3000 tons of shipping ore, which will be sent to Tonopah mills.

New companies that have equipped their ground for deep work, include the Florence Divide, Mohawk Divide, Divide Annex, North Divide, Hennessy Divide, Silver King Divide, and a half-dozen more. All roads are alive with freight-teams, motor-trucks, and touring-cars, bringing in equipment and visitors.

A list of companies operating in the Divide district is as under:

Name	Shares	Par value	Development
Tonopah Divide Mining Co.	1,250,000	$1.00	Shaft 520 ft.; ore-reserves $5,000,000; shipping to Tonopah
Brougher Divide Mining Co.	1,000,000	1.00	Shaft 500 ft.; cut Divide vein on 177 and 500-ft. levels
Gold Zone Divide Mining Co.	1,500,000	0.10	Shaft 500 ft.; cut Divide vein on 295 and 500-ft. levels
East Divide Mining Co.	1,500,000	0.10	Shaft 320 ft.
Divide Extension Mining Co.	1,000,000	0.10	Shaft 170 ft.
Tonopah Hasbrouck Min. Co.	1,500,000	1.00	Shaft 400 ft. and tunnel 900 ft.; ore-reserves $50,000
Divide Consolidated Min. Co.	1,500,000	0.10	Started shaft
Tonopah Dividend Mining Co.	1,500,000	0.10	Shaft 300 ft.; cut two wide veins
Alto Divide Mining Co.	1,500,000	0.10	Started shaft
Sutherland Divide Mining Co.	1,500,000	0.10	Incline shaft 400 ft.; two shallower shafts; will sink 200 ft deeper
High Divide Mining Co.	1,000,000	1.00	Not yet working
Gold Wedge Divide Min. Co.	1,500,000	0.10	Started shaft
Rosetta Divide Mining Co.	1,500,000	0.10	Started shaft
Divide Annex Mining Co.	1,000,000	0.10	Will sink shortly
Allied Divide Mining Co.	1,500,000	0.10	Will sink shortly
Silver King Divide Min. Co.	1,000,000	0.10	Started shaft
North Divide Mining Co.	2,000,000	0.10	Sinking shaft
Florence Divide Mining Co.	1,500,000	0.10	Will start soon
Mohawk Divide Mining Co.	1,500,000	0.10	Ready to sink
Divide City Mining Co.	1,500,000	0.10	Starts shortly
Goldsmith Divide Mining Co.	1,500,000	0.10	Not yet working
Gold Reef Divide Mining Co.	1,500,000	0.10	Starts work soon

400-TON CYANIDE MILL OF THE ROCHESTER COMBINED MINES, NOW PART OF THE ROCHESTER NEVADA SILVER MINES CO.

A recent meeting of mining men at Divide formally named the place the Divide Mining District. It has no post-office or camp, and mail goes to Tonopah. A townsite is to be organized shortly, on the claims of the Divide City Mining Co., on the main road, just north of the Mammoth claim of the Tonopah Divide group.

GOLDFIELD, NEVADA

Development of the Florence.—The Consolidated in 1918.

Following a recent examination of the Florence Goldfield mine, F. Sommer Schmidt, representing New York interests, reports that with exception of legal details, the shares owned by A. D. Parker and the estate of Thomas G. Lockhart has been sold to them. The deal involved, according to J. W. Dunfee, of Goldfield, who was instrumental in making the sale, 318,650 shares owned by Parker and 314,000 owned by the Lockhart estate. The purchase price is said to have been $100,000. Ample funds for development of the Florence will be provided, without the sale of additional treasury shares. The company proposes to sink the 1200-ft. shaft to the shale-latite contact, and will investigate the possibility of mining a large block of ground by the caving system, as is contemplated by the Goldfield Development Co. on the same vein. It is reported that leases on the upper levels of the Florence will be renewed by the company after expiration on January 1, 1920. One of these leases—the Witt-Brandon-Taylor-Mechlin—has exposed for a distance of 41 ft. on the 400-ft. level, a seam of ore from 6 to 18 in. wide, from which high assays are obtained. From 4 to 6 ft. of material assaying from $400 to $500 per ton is being broken in a drift on this level. Ten lessees are operating, but the one mentioned is the only one producing regularly. On the same vein, on the 350-ft. level, the Cracker Jack company has a lease, and has started raising through the vein to open the rich shoot exposed in the Witt lease. The Red Hill-Florence, owning adjoining claims and holding a lease on the Florence, is being developed on the 600-ft. level, to the south and on the same vein. The Florence has produced over $7,000,000, and during the period of the receivership, from November 1916 to October 1918, the gross value of ore produced was $225,000.

The report of the Goldfield Consolidated Mines Co. for the year ended December 31, 1918, states that 94,654 tons of ore, worth $1,065,381, was produced. Of this, $921,514 was extracted. Also, 164,121 tons of tailing was treated, from which $116,804 was extracted. Operating charges, including sums paid to lessees, totaled $1,059,696, leaving a net balance of $3433. Development amounted to 4848 ft., performed at a cost of $6.72 per foot. Operation was continuous throughout the year, except for a short period in July; but at the close of the year less than 150 tons of ore was being treated daily. As is well known now, on February 1, 1919, the property was leased to the Goldfield Development Co., and two claims were sold to this company. At the end of the year the Consolidated company had on hand $136,062 in cash. No dividends have been paid since October 30, 1915.

PLATTEVILLE, WISCONSIN

Blende, Carbonate, Lead, and Pyrite Mining and Prices.

The zinc situation in the Wisconsin field for February was bad, to say the least. The Government has, for instance, 1200 tons of spelter at the Hillsboro, Illinois, plant alone, a drug on the market, which speculators believe will be thrown on the market at an early date, and so depress the price of spelter further. Until the stock on hand is worked off, and business conditions improve, it is difficult to expect anything better in the ore business for several months. Leading smelter officials interviewed personally profess to believe that by autumn of this year we ought to be doing better than now, but not before then.

Operating conditions in this field last month were satisfactory to the mine manager, and a fair recovery was obtained, although with greatly reduced working forces. Several low-grade zinc-ore producers shut-down on account of low markets and irregular demand. In the Benton district, the Frontier Mining Co. alone released 200 men and closed three producers. At all points mines suspended operations temporarily, some with bins well stocked with surplus ore. One consistent producer suffered the loss of its surface plant by fire, a score of miners losing their jobs there. Little prospecting is being carried out.

Prices were not regarded as satisfactory by ore sellers. The high-grade product obtained by roasting and electrostatic separation diverted to the uses of sheet-zinc makers held all month on a $45 per ton base, with some premium grade at times realizing prices in advance of this. On second grade, high-lead blende, prices ranged from $40 to $43.50, with the bulk of the sales on a $42.50 base. It was this figure that enabled most operators to continue, otherwise the shut-down might have been more general. The Matthiesen & Hegeler Zinc Co., for 25 years one of the most aggressive as well as liberal buyers of zinc ores of high grade, was practically out of the market. Low-grade producers had an exceedingly bad inning. The reserve of zinc ore in the field at the close of the month showed 7500 tons of all grades.

Producers of lead ore were given severe set-backs during February, and sales and shipments of this class of Wisconsin product were exceedingly light. The price held at $55 at the beginning of the month, but demand was painfully absent and buyers showed no real interest. The price receded to $50, and at one time offerings were made under this figure. Toward the close of the month some competition developed and interest shown by a new lead-smelting concern, at Wauwatosa, Wisconsin, caused prices to take an upward trend. Deliveries agreed upon at the close of the month found the offerings in advance of $60. It was held that improvement in the pig-lead market suggested the advance in the price of ore, which may be true, but competition in ore buying helped materially. The reserve in all at the close of the month was in excess of 1000 tons, all choice high-grade lead concentrate. Shipments out of the field for the month were 240 tons. Producers took advantage of fine weather to invade shallow and surface diggings, making a fair production.

Pyrite was not in good demand at any time, although commercial sulphuric acid ruled high. At Mineral Point, one of the reduction plants was closed, but the McDougall furnace in one of two plants was run on ore separation and for making acid. Fine ore recovered at separating plants, has been accumulating since early last autumn, and there is now in the field a reserve amounting to several thousand tons. It is said the two new Government acid plants, built last year, are for sale, and that local mining corporations are negotiating for their transfer.

Production of carbonate of zinc ore has taken on new impetus in the northern districts of the field, the New Jersey Zinc Co. opening large deposits. Much ground proved by drilling is being exploited. Machinery is being erected, and more miners are being employed, instead of curtailing operations. Prices continue to be satisfactory, as high as $35 per ton being paid for 40% zinc content, but the average for the month was $28. This ore is cheaply mined. During cold weather, concentrating this ore is almost impossible, so it is shipped direct to the oxide furnaces at Mineral Point. It is here converted into the oxide, and packed in 300-lb. barrels. At this time it is said that the Mineral Point Zinc Co. has its warehouses filled with the oxide, in excess of 50,000 barrels.

THE MINING SUMMARY

ALASKA

Kennecott.—The Kennecott Copper Corporation has declared a quarterly dividend of 50 cents per share, half of the previous one.

ARIZONA

Bowie.—The Helen-Dome, a gold-silver-lead mine in the Dos Cabezos, is being operated under bond and lease. Mine machinery and a 25-ton mill are arriving at Bowie.

Copper Hill.—The Superior & Boston Copper Co. has issued a report for the year ended September 30, 1918. A. L. Graham is superintendent. Receipts were $246,158 from ore sold to the El Paso smelter, and $104,828 from calls. Development cost $110,485, and ore extraction $223,896. The balance from 1917 was $141,577, and that carried to 1919 was $129,374. Exploration was mainly in the eastern part of the mine, on the 800 and 1000-ft. levels, also reopening the 1200-ft. level. Faults were encountered, and the formation on the two upper levels was much leached and oxidized. Work was therefore suspended there and transferred to 1200 ft. to get under this material. A total of 199 ft. of work was done. Above the 800-ft. level, 100 ft., a body of oxide ore was opened, in places 20 ft. wide, carrying 6% copper. Ore shipments totaled 22,751 tons, assaying 3.88% copper and 0.4 oz. silver. A profit of $1.03 per ton was made, but at present costs and prices a loss would result.

Hackberry.—The new mill of the Hackberry Consolidated Mining Co. is ready for operation. The mine is said to be in good condition to supply the mill, there being sufficient ore broken in the stopes to supply the mill for some time.

Mayer. The Arizona Binghampton Copper Co. has purchased the Hazel and Gold Hill claims for $10,000. These are contiguous to the Binghampton.

Prescott.—The Anderson silver claims in the Thumb Butte district are to be opened within the next 30 days. A little development was carried on during the War.

Ray.—The Ray Hercules in February concentrated 733 tons of 1.427% ore daily, recovering 80.5%. On March 1 the mill treated 1130 tons of 1.705% ore, recovering 88.5%.

Superior.—The Maverick group of 20 claims in the Superstition mountains, owned by Woodbury brothers, have been sold to the Pillsbury interests for a consideration said to be $100,000. The property is to be churn-drilled.

Tucson.—The concentrating and cyanide mill of the El Progresso Mining Co. is ready for operation. This mill will treat 500,000 tons of ore now on the dump.

COLORADO

Breckenridge.—The Juventa Mines Co. has been organized to resume work on the Juventa claims, idle for 18 years. The main tunnel is in 1200 ft. Some deposits of iron-manganese ore have been developed. Possibilities are considered good.

The Gold Belt Mining Co. has been formed to operate a property on Brewery hill, 5 miles east of Breckenridge. It is well developed and heavily timbered.

Lawson.—The Matrix Mines Co. has increased its capital from $30,000 to $95,00. It has a lease on 16 claims, 8 miles from Idaho Springs, on which work has been under way for two years. Some good silver-lead ore has been opened. Shipments are to be started by mid-summer.

Pitkin.—The Pennsylvania Molybdenum Mines Co. has started its new flotation mill. S. G. Fetterman is manager.

IDAHO

Stites.—According to Mr. Roebuck, this town is to construct the first 13 miles of the 52-mile road to the Elk City, Orogrande, and Ten Mile gold districts. At that point the road would enter the forest reserve, after which the Federal government might finish it.

Talache.—At the Armstead Mines property in Bonner county, in charge of D. G. McLachlan during the absence of H. H. Armstead, who was in the Engineers, a 600-ft. raise has connected No. 3 and 2 tunnels, giving an exit through No. 3, which is 4000 ft. long, of 1600 ft. of backs.

Wallace.—Wages in the Coeur d'Alene region were reduced by $1 per day on March 16. Under the sliding-scale in force this is still 50 cents higher than provided for. Miners will now receive $4.25 per shift. Lead is selling at 5.25 cents per lb., and the following schedule shows the wage-bonus paid and the lead prices controlling same:

Price per 100 lb.	Bonus
$5.00 to $5.50	$0.25
$5.50 to $6.00	0.50
$6.00 to $6.50	0.75
Above $6.50	1.00
Above $7.50	1.25
Above $8.00	1.75

The operators are hopeful that lead prices will permit the maintenance of the proposed scale at least until living costs have been reduced or the price of lead substantially raised. If it were not for the high silver price it is safe to say every mine in the district would now be closed. The disquieting part of the present position is the lack of a market for lead. It is perhaps not known generally that there is piled up in the yards at the Bunker Hill, at Kellogg, smelter more than 5000 tons of lead bullion. This has accumulated since November 11, and is sufficient to supply all demands on the Bunker Hill smelter, as they are at present, for the next four or five months. It is generally believed that the proposed cut will be accepted without protest.

KANSAS

Pittsburg.—The Newkirk Smelter Co. is to remove the 8-block, 16-furnace zinc plant of the Pittsburg Zinc Co. to Newkirk, Oklahoma. Instead of coal, gas will be used as fuel.

MISSOURI

Duenweg.—The Coahuila Lead & Zinc Co. has closed its No. 3 mine at Porto Rico. The reasons for this are low prices for zinc ore and excessive water, due to adjoining mines being closed. From 1909 to 1916, the company operated a 900-ton mill (24 hours), after which the new 1400-ton mill was started. In 10 years, 2,040,031 tons of ore was hoisted, 362,506 tons being in 1917. C. S. Smith designed the new plant, which recovered 79%. Total costs were from

$1.16 to $1.25 per ton during the past three years. D. D. Dunkin was in charge recently.

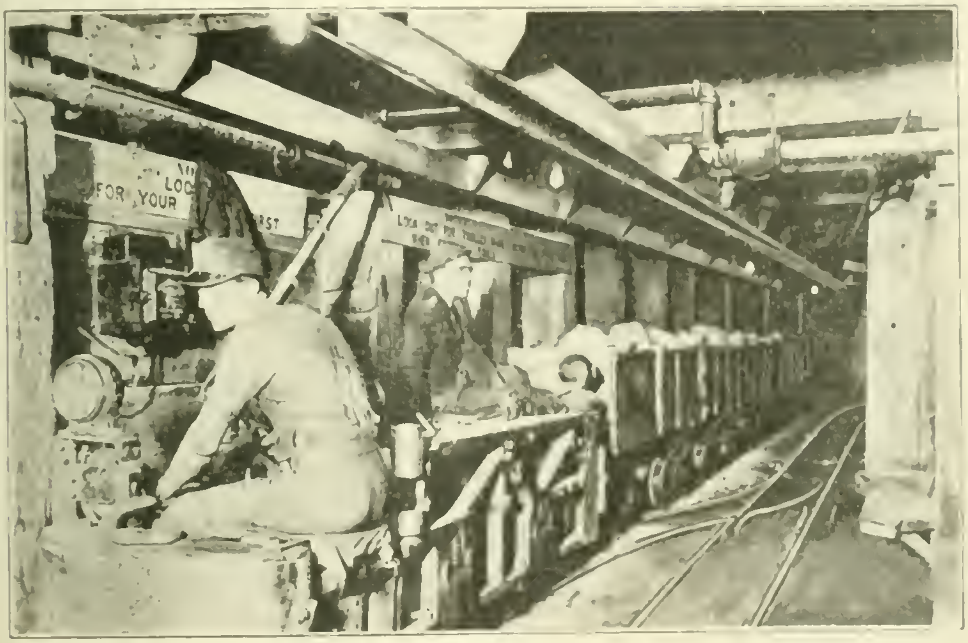
Joplin.—Production of the Tri-State region last week was as under:

State	Blende, tons	Calamine, tons	Lead, tons	Value
Kansas	1350		181	$69,153
Missouri	1052	108	233	60,081
Oklahoma	6394	..	1031	336,802
Total	8796	108	1445	$466,036
Average price	$42	$28	$92	

MONTANA

Butte.—The Butte & Superior company produced 4,175,000 lb. of zinc and 78,000 oz. of silver during February. This is only one-third of the same month of last year.

The Tuolumne Copper Mining Co. held its annual meeting here last week. In spite of spending $66,086 on development, and $34,174 on repairs, etc., there was a net balance of $26,843 at the end of 1918. New openings amounted to 6543 ft. The Main Range mine yielded 25,405 tons assaying 2.253% copper, 8.082 oz. silver, and 0.0075 oz. gold. Net smelter returns were $248,221, equal to $10.54 per ton. The Spread Delight vein at 700 and 800 ft. produced this ore. At 800 ft. the shoots are over 500 ft. long, and are from 5 to 35 ft. wide. Until the Main Range has been opened to 1200 ft., and connection made with the Colusa-Leonard, no further work will be done in the latter mine. Production of the Main Range in January, 1919, was 6682 tons, averaging 3.057% copper, 10.235 oz. silver, and 0.01 oz. gold, giving a profit of $17,227; and in February, 2840 tons of 2.18%, 7.03 oz., and 0.0075 oz., and $7684 profit. Paul P. Gow is general manager, H. M. Fay, assistant, and M. Little superintendent.



ELECTRIC TRACTION UNDERGROUND AT BUTTE

Troy.—The Snowstorm Mines Consolidated is treating 6000 tons of ore monthly. The No. 7 tunnel is in over 1500 ft., with 950 ft. to go.

NEVADA

Goldfield.—The Goldfield Development Co. contemplates treating a large quantity of ore from Combination hill. A drift on the 380-ft. level of this mine is to be extended, preparing a block of ground 40 by 1000 ft. to that depth. Over 1000 samples from this area give an average of $5.60 per ton, and milling 1000 tons daily total costs would be $2.00 per ton. The caving system of mining is suggested.

Hilltop.—Three horse-teams are hauling ore from the Kimberly Consolidated mine to Battle Mountain. The mine is 19 miles from rail. It is reported that the company is to build a flotation plant at an early date, also add more mine equipment. Machine-drills were recently installed. The property produces silver-lead and copper ores.

Mina.—Twenty-two miles east of this place is the Simon lead mine, which, under O. E. Schiffner of Tonopah, is said to be developing into a large producer. Machinery includes a 25-hp. Fairbanks-Morse gasoline hoist, and 3-drill Sullivan compressor. The shaft is 300 ft. deep, and is to be sunk further. At 230 ft. is 35 ft. of $25 lead-zinc ore, while at 300 ft. there is similar ore.

Pioche.—The Prince Consolidated Mining & Smelting Co. in 1918 made an operating profit of $78,969, according to the general manager, M. C. Godbe. There was sold 84,137 tons of iron and silicious ores and concentrates. General results were good. The Prince orebody was proved for over 575 ft. farther to the south than before. Better grade shoots were developed. While the Bullionville mill will not recover what was expected, it can be operated profitably, and when the ore available has passed through, there will be in one pit 100,000 tons of tailing for cyanidation, assaying 8 oz. silver, $1.80 gold, and 3% lead. Two new diamond-drill holes from No. 6 level have cut ore; one passing through 10 ft. of iron-manganese, assaying 25 oz. silver and $3.60 gold; the other 11 ft. of clean sulphide carrying 30% zinc. The mine was examined by F. J. Pack of the University of Utah.

Tonopah.—Net earnings of the Tonopah Mining Co. in 1918 were $782,000, against $825,000 in 1917. Dividends were $375,000, a decrease of $225,000.

TEXAS

Austin.—The 'blue sky' law introduced by Senator Dorrough is not likely to pass the House at this session, although it passed the Senate two weeks ago. Oil interests are said to oppose the measure.

Burkburnett.—Since August last, when the Fowler oil-well was brought-in, this town has grown from 200 to over 15,000 people. A veritable oil-boom is raging here and at Ranger. The first well is only 1700 ft. deep. There are now over 100 producing wells, each said to be yielding 1000 barrels.

UTAH

Alta.—The Wasatch Mines Co.'s tunnel is in 3650 ft., and is being advanced 200 ft. per month. The face is 700 ft. from the Howland ore in the Columbus property. The opening is 7 by 9 ft., and will eventually be the most convenient outlet for the Columbus-Rexall, Emma Consolidated, Sells, Michigan-Utah, South Hecla, and Cardiff properties, such as are in Big Cottonwood, having only a short distance to go to reach the Wasatch tunnel outlet.

Park City.—This district produced 9770 tons of ore in

February, compared with 10,632 tons in January, a longer month. The Silver King Coalition and Ontario Silver produced 2677 tons each, followed closely by the Judge with 2608 tons.

Tintic.—This district produced about 2600 tons of ore during February, which is below the average for January.

WASHINGTON

Chewelah.—The United Copper Mining Co., according to Conrad Wolfle, will not increase its capital as proposed. Developments are very encouraging, and 15 machines are working two shifts. The winze is down 67 ft. below the 1300-ft. level, showing 5 ft. of ore, 2 ft. of which assays 16% copper and 200 oz. silver per ton, the remainder 5% and 20 oz. Emanuel Wolfle is assistant manager, Thomas Ferguson, mine superintendent; B. E. Bell, mill superintendent; and P. A. Brady, engineer and assayer.

Olympia.—By a vote of seven to five, the Rules Committee of the House of Representatives on March 5 refused to place the Fawley 'blue sky' bill upon the calendar, thus killing it for this session.

CANADA

British Columbia

Alamo.—The Lucky Jim company is to send 2000 tons of zinc ore to the mill built by Clarence Cunningham for concentrating tests. Another lot will be sent to the General Engineering Co. at Salt Lake City for experiments with the Callow process.

Anyox.—Announcement is made that the employees, 1200 men, of the Granby Consolidated have decided, after deliberating for six days over the company's proposal to return to the sliding-scale of pay, with certain other concessions, to reject such an arrangement for the continuance of the work at the smelter. The vote showed a majority of only 19 in favor of refusing the terms offered. As a result the plant has been shut-down, and the men are losing $7500 daily. There has been no trouble here, and it is hoped that in a few weeks, perhaps by the time the damage caused by the recent fire (damages $50,000) are repaired, an amicable settlement will have been reached.

Grand Forks.—The Granby Consolidated has blown-in another furnace, making three in blast. Wages have been reduced 25 cents per shift, yet they are 50 cents higher than the pre-war rate.

Kaslo.—The Utica Mines company, in charge of W. F. Caldwell, has taken over the Bell and Sunset claims.

Lillooet.—The discovery of copper deposits at the head of Gun creek on Copper mountain in the Mackinnon range is reported, and it is stated that the area has been examined by Charles Camsell, of the Dominion Geological Survey, and who will publish a report shortly. He visited the region last summer, and is said to have formed a favorable opinion.

Nelson.—The Mountain Chief mine has been acquired by a syndicate headed by J. W. Evans. On the reported purchase price of $150,000, a payment of $15,000 has been made.

Sandon.—On No. 10 level of the Silversmith mine there is lead-zinc ore for a length of 325 ft. Crude ore being shipped assays 40% lead and 90 oz. silver per ton.

Trail.—The assistant general manager of the Consolidated M. & S. Co., S. G. Blaylock, in a recent statement asserts that there has been no change in the wage-scale at the Trail smelter since June 1, 1918.

Ontario

Cobalt.—The Mining Corporation pays a dividend of 12½%, equal to $207,455, on March 31. This brings the total to $6,113,400.

The McKinley-Darragh-Savage company's profit in 1918 was $295,662. Dividends absorbed $269,723. The tailing mill (flotation) is to resume work in the spring.

Kirkland Lake.—The new 30-ton mill at the Burnside is in operation. It is proposed to amalgamate this property with that of the Tough-Oakes and Sylvanite.

The Ontario-Kirkland is sinking its shaft 4 ft. daily, the present depth being below 150 feet.

Porcupine.—The Dome Extension property is to be sold to the Dome Mines company for 76,667 shares of the latter.

The Schumacher company is preparing to unwater its mine, which is 700 ft. deep. The 180-ton mill is ready to resume ore treatment.

KOREA

Seoul.—During the past year the Seoul Mining Co. treated 201,151 tons of ore, yielding gold worth 2,892,385 yen, or about $1,446,000.

Unsan.—The Oriental Consolidated cleaned-up gold worth $102,000 in January. In November, 160 stamps crushed 21,326 tons, with the cyanide plants recovering $129,155 of gold. Operating costs, $67,546, and improvements, $75,725, left a deficit of $14,117. In December, 22,181 tons yielded $124,350. While the mills were operating at full capacity, there was a shortage of 350 men underground. Progress on the new power project is good. The February output was $88,000.

MEXICO

Hidalgo

Pachuca.—Santa Gertrudis in January treated 30,970 tons of ore, making a profit of ₱24,720 ($117,000).

Jalisco

Guadalajara.—The Chamber of Mines of Guadalajara has been formed here to assist the development of mining and allied industries in Mexico. The president is Othon Camarena; vice-president, Manuel F. Chavez; and secretary-treasurer, W. J. Pentland. The mining companies in the Chamber are as follows: Amajac Mines Co., Amparo Mining Co., Cinco Minas Co., Castellana Mining Co., Cia. Minera de la Española, Cobre Grande Mining Co., El Carmen y Anexas, El Favor Mining Co., E. R. Downs, Magistral Mining Co., Mezquital Mining Co., Mexican Mines Co., and Navidad Development Company.

Mexico

Mexico City.—According to a dispatch from Washington, D. C., on March 5, mine operators of four Mexican States have united in a request to the Secretary of Commerce, Industry, and Labor of the Mexican cabinet that a general mining congress be called to meet at an early date in Mexico City for discussion of all questions relating to the industry. Official dispatches state that the question of high explosives was one of the chief problems of Mexican operators. National and international restrictions were said to operate so as to prevent securing a sufficient supply.

The National Association for Protection of American Rights in Mexico, with head offices at New York, and backed by influential mining and oil companies, has issued a call for members, saying the well-being of the Mexican people themselves as well as lives and property of foreigners are to be protected from chaotic conditions prevailing. "We wish to emphasize the fact that it is the desire of this Association," the circular states, "not to embarrass our government and not to bring it into conflict with the Mexican government; but its chief aim will be to work with both governments upon a friendly and helpful basis. If such a program can be carried out, the organization can be of great service in assisting to remove causes of friction between the United States and Mexico."

Sonora

Cumpas.—Closing of copper mines and the long drouth has resulted in much depression in this district, 150 miles south of Douglas, Arizona.

Nacozari.—Conditions are practically normal and miners are plentiful in northern Sonora, says J. S. Williams, Jr., general manager for the Moctezuma Copper Co., in a recent communication to Sill & Sill of Los Angeles, according to the Bulletin of the Chamber of Mines and Oil. Mr. Williams gave an interesting analysis of taxation in Sonora, covering State, Federal, and municipal taxes, as follows:

State—2% on the value of all ores, concentrates, and metals exported. Valuation of gold is fixed at ₱1333.33 per kilogramme; valuation of silver is governed by current prices of metals in New York. Thus, the tax for January 1919 would be as follows: gold, 2% on ₱1333.33; silver, 2% on ₱65.025; ₱5 per ₱1000 per annum on value of plant buildings, machinery, and stocks of supplies carried.

Mercantile business is taxed ₱8 per ₱1000 per annum on the value of merchandise stocks carried in stores, plus 60% contribution to the Federal government; 2% on all sales of merchandise, both wholesale and retail, plus 60% contribution to the Federal government.

Federal taxes on mining claims—Pertenencias, with the annual tax on each division, as follows: 1 to 5, ₱6; 6 to 50, ₱9; 51 to 100, ₱12; and 100 or more, ₱18. The tax is payable each third of the year, or every four months, in advance. The progressive rates are applicable provided that the pertenencias belong to a single owner and are in the same mining district.

Eight per cent on the value of the gold and silver when these are exported in the form of mineral rock or earth, concentrates, cyanides, sulphurets, smelter residue, or in any other form in which they are found combined or mixed with substances which are not metals, properly speaking. Seven per cent on the value of the gold and silver exported, these having been treated in the country up to the point where they are not alloyed or mixed, except with other metals and whatever be the assay-value of the product. For the collection of the tax on ores exported, pure gold shall always be considered at the rate of ₱1333.33 per kilogramme, and for silver and other ores the Department of Hacienda shall issue each month a tariff to govern in the following month, taking as a basis the current prices of the metals, metallurgical products or natural ores in New York, and in accordance with the special circumstances of each case. Thus, the tax for January 1919 would be as follows: gold in ores or concentrates, ₱106.67 per kilogramme; in bars (treated in the country), ₱93.33; silver, in ores or concentrates, ₱5.205; in bars (treated in the country), ₱4.561.

Exporters of mixed bars of any assay-value in gold and ores or cóncentrates of any class, when these contain an assay-value in gold greater than two grammes per ton, shall re-import into the country precisely in coinable gold bars or in Mexican or foreign gold coins an amount equal to that of the gold contained in the bars and products exported.

Exporters of refined or mixed silver and of ores or concentrates of any class when these contain an assay-value of silver greater than 250 grammes per ton, must re-import into the country precisely in coinable gold bars or in Mexican or foreign gold coins, a percentage which periodically and in each case shall be fixed by the Department of Hacienda on the value of the silver contained in the bars, minerals, or concentrates extracted.

The assay-tax is fixed at ₱3 for each lot of 20,000 kg. of ores and concentrates exported.

All receipts given must be stamped as follows: Up to ₱40, 5 centavos; ₱40 to ₱100, 10 c.; and over ₱100, 5c. for each ₱40 or fraction. Stamps must be affixed on all pay-rolls where earnings of salaried men appear, wages of day laborers excepted. The rate is the same as for receipts.

Municipal—Stores from which sales of merchandise or supplies are made pay the following tax: 1st class, ₱100 to ₱800 per month; 2nd class, ₱30 to ₱95; and 3rd class, ₱5 to ₱25. On the above tax, the Federal contribution is 60%.

PERSONAL

Note. The Editor invites members of the profession to send [illegible] of their work and appointments. The information is interesting to our readers.

Myron A. Folsom is in the Ranger oilfield of Texas.

H. B. Lowden, of the Colorado Iron Works, was in San Francisco last week.

C. Yen, recently in Michigan and New Mexico, sailed on March 15 for Shanghai.

F. L. Firebaugh, Lieutenant in the A. E. F., has returned to Berkeley from France.

Oscar V. White has resumed his former position as superintendent of the Silver Smith mine, Slocan, B. C.

Wilbert V. Certon has opened an office of information on mines in Central America at Tegucigalpa, Honduras.

Frank Merricks passed through San Francisco on his way from London to China, sailing from here on March 15.

John Linn, of Oakland, has been appointed general superintendent of the Empire copper mine, at Mackay, Idaho.

G. W. Eade has taken the position of chief electrician for the Wolverine and Mohawk mines, succeeding **Joseph Mette**.

S. K. Dahl, mill superintendent for the Messina Development Co., in the Transvaal, was here and has gone to New York.

C. W. Beauchamp is still with the 28th Engineers, now at St. Maurico in the St. Mihiel sector of the former French front.

Clark G. Mitchell, managing director of the Isabella Mines Co. at Cripple Creek, has resigned. **Frank Gunn** continues as superintendent.

Charles Camsell, head of the Geological Survey in British Columbia, has gone to Ottawa to arrange for field work for the coming season.

Alan M. Bateman, professor of the Department of Economic Geology, Yale University, has become editor of the 'Journal of Economic Geology'.

R. G. Wayland, formerly general superintendent at the Alaska Treadwell, has been appointed chief engineer to the Homestake Mining Co. in South Dakota.

George R. Tingle, formerly mill superintendent for the Syndicate Mining Co., at Aroroy, Masbate, Philippine Islands, passed through San Francisco this week.

Ernest W. Ellis, Lieutenant in the field artillery of the 13th division, has accepted a position in the experimental metallurgical plant at the Bunker Hill & Sullivan mill.

Donald C. Smith has resigned as metallurgist for the Penn Mining Co. and has accepted a similar position with the Afterthought Copper Co., at Ingot, California.

Herbert C. Enos, formerly manager for the Cia. Minera y Fundidora Internacional, at Matehuala, Mexico, will engage in consulting work with headquarters at San Luis Potosi.

Henry H. Armstead has received his discharge from the Corps of Engineers and has been re-commissioned for five years as Major in the Engineers Reserve Corps. He has returned to Talache, Idaho, to take up again the active direction of the Armstead Mines, Inc., and will also give personal attention to the Utica Mines at Kaslo, British Columbia.

Philip N. Moore, past president of the A. I. M. E., has been appointed by the Secretary of the Interior to serve on the commission to adjust claims growing out of governmental efforts to stimulate production of war minerals. The other members of the commission are **J. F. Shafroth**, formerly Senator from Colorado, and **M. D. Foster**, ex-member of Congress from Illinois.

The American Electrochemical Society holds its annual meeting at New York on April 3 to 5.

THE METAL MARKET

METAL PRICES

San Francisco, March 18

Aluminum-dust, large and small lots, cents per lb	65—70
Antimony, cents per pound	8.00
Copper, electrolytic, cents per pound, in carload lots	15.00
Lead, pig, cents per pound	5.50— 0.50
Platinum, per ounce	$100
Quicksilver, per flask of 75 lb	$08
Spelter, cents per pound	8 00
Zinc-dust, cents per pound	12.50

EASTERN METAL MARKET

(By wire from New York)

March 18.—Copper is quiet and steady. Lead is inactive but firm Spelter is dull and unchanged.

SILVER

Below are given official (not Government) quotations, in cents per ounce, of silver 999 fine. In order to make prompt settlements with smelters and brokers, producers allow a discount from the maximum fixed price of $1.01½, hence the lower price. The Government has not fixed the general market price at $1, but will pay this price(as from April 23, 1918) for all silver purchased by it. The equivalent of dollar silver (1000 fine) in British currency is 46 65 pence per ounce (925 fine), calculated at the current rate of exchange. On August 15, 1918, the Treasury announced that the maximum price was fixed at $1.01½ per ounce. The British government fixed its maximum at 49½ pence, on September 2, but on November 12 this was changed to 48¾, on December 13 to 48 7/10, and in February to 47¾ pence.

The conclusion arrived at by the 'Metal World' of London is that a big trade in silver will be done as soon as the markets are free from control, and while high prices may stimulate production, this will not be sufficient to hold the market down for a long time to come.

The silver market in London remains steady, according to Samuel Montagu & Co. The Shanghai exchange has receded to 4s.7½d ($1.11). Doubtless the easier tendency is owing to the completion of an arrangement by which China will receive a substantial amount of silver from America The Indian Currency report for 1917-'18 has the following: "The rupee coinage of the year was 2312 lacs (1 lac. = $32,000) and purchases of silver for this coinage amounted to 83,750,000 oz. These were supplemented by local purchases in Bombay and Calcutta of 3,500,000 oz. There were purchased in America, 40,000,000, in China 28,000,000, and in Australia 5,000,000 oz., while 1,750,000 oz was obtained from the Bawdwin mines (in Burma) The balance was shipped from London."

Copper production of the large mines in February was as under:

Name	Pounds	Name	Pounds
Anaconda	12,400,000	Miami	4,402,578
Arizona	3,360,000	Nevada Consolidated	4,150,000
Calumet & Arizona	5,028,000	New Cornelia	2,872,000
Calumet & Hecla and subsidiaries	10,263,808	Ohio	395,150
Cerro de Pasco	4,586,000	Phelps Dodge (Copper Queen, Detroit, Burro Mountain, Moctezuma)	9,185,000
Chino	3,552,000	Ray	4,150,000
East Butte	633,500	Shattuck	376,160
Greene-Cananea	3,000,000	Utah	10,335,000
Inspiration	6,000,000		
Kennecott (and Braden)	5,292,000		

According to S R Guggenheim and others just returned from Europe, it will be a long time before a large foreign outlet can be expected for American copper. Further curtailment of production is hinted at in this country.

According to D C. Jackling at Salt Lake City recently nobody can safely predict the immediate future of copper.

ORES (New York)

Manganese. It is stated that Indian ore has been offered as low as 45c. per unit, the ore to be shipped in ballast, thus reducing freight charges.

Manganese-Iron Alloys. Ferro is selling only in small lots at $150 delivered, mostly re-sale material. Producers quote $200 for 80% alloy with $3 per unit deducted for each per cent under 78%. Spiegel is nominal at $40 to $45 delivered, with no demand. The output of ferro in February was 21,796 tons, compared with 21,331 tons in January, much in excess of needs and of the earlier expectations in the trade. The February production of spiegel was only 6300 tons, against 11,456 tons in January and much higher average per month in 1918.

Molybdenum. The market is devoid of demand and nominal at about 85c. per lb. of MoS_2 in 90% concentrates.

Tungsten. Inquiries are few, and the market is very inactive with practically no test of prices. As low as $9 to $10 per unit is heard of for certain grades, but there is no buying. In the meantime stocks are being consumed and the position is improving to this extent only. No one seems to know what ferro-tungsten could be bought for—certainly at a little less than $1 50 per lb. of contained tungsten.

Eastern Metal Market

New York, March 12

The markets are all quiet, but the general tone is better, with prices of most metals firm.

Antimony is inactive.

Copper sold at lower levels last week, but it has again advanced and inquiry is better.

Lead is quiet but firm.

Tin is at a standstill, being still under control.

Zinc demand is still light, and the price tendency is lower.

COPPER

After a further recession in prices on small sales to as low as 14.50c. per lb. for electrolytic copper in the last week, the market has turned stronger and is now back to 15c., New York, for early delivery. It is stated that a considerable buying movement, small as compared with normal times but large as judged by recent events, appeared last week, and one producer stated to the writer of this letter tha he has sold copper every day this month at not less than 15c. The feeling is general that a turn has come, but some sellers doubt the endurance of it, one stating that he expects lower prices again. The situation as a whole, however, is brighter than in some weeks. The basis for improvement is not tangible, however. There is little export demand, nor is domestic demand broad. Lake copper is nominal at about 15.75c., New York. It is the understanding that the arrangement reported last week, whereby the producers will sell the Government stocks of copper, has been ratified by the Federal authorities. British stocks of copper on March 1 were 51,379 tons, against 27,530 tons on December 1, 1918.

LEAD

The market has lost its recent activity, and is now quiet but firm. The quotation of the American Smelting & Refining Co. is unchanged at 5.25c., New York, or 5c., St. Louis, with that of the outside market a little easier at 5.30c., New York. The general situation is unchanged, and fundamental conditions are sound. Buyers' wants have been temporarily satisfied. Stocks of lead in Great Britain on March 1 are officially reported as 100,063 tons, compared with 49,111 tons on December 1, 1918.

TIN

The market continues at a standstill, and there is little of interest. Governmental control continues, with Straits tin available at nothing lower than the fixed price of 72.50c., New York. Imports continue prohibited, and there is no free market except in quantities of 5 tons or less. The rumor mentioned last week developed into a certainty in that an attempt was made to increase the price of American tin so as to lessen the competition with the allocated. While this was in progress there was a fair demand for tin, but this has died out. American 99% metal is available at about 68c. per lb., New York. There has been some buying of future tin for shipment to England to be held there until American import restrictions are removed, but it is estimated that this has not exceeded 200 to 250 tons. The tin has probably been bought at from 46 to 54c. per lb. It is calculated that 6000 tons of the 10,000 tons of allocated metal has been disposed of, and that it will be at least two months before the rest is taken up and a free market results. Arrivals thus far in March have been 850 tons, all at Pacific ports. The London market is higher at £243 per ton for spot Straits on March 10.

ZINC

There is no life to the market, and demand continues insignificant. It is hardly enough to establish quotations which have receded slightly in the past week. They are largely nominal at 6.15c., St. Louis, or [illegible], New York, for prime Western for early delivery. Consumers are still showing no disposition to buy, and producers are not forcing the market. It is understood that sales last week were made as low as 6.12½c., St. Louis, but that at this level a speculative movement appeared causing the market to grow firm. This has, however, died out.

TEXT OF MINERALS RELIEF BILL

The War Minerals Relief Measure, referring to producers of chrome, manganese, pyrite, and tungsten, is known as Section 5 of the Dent-Chamberlain War Contract Validating Bill, and became law on March 3, 1919. The State Mineralogist, Fletcher Hamilton, desires to call the attention of the Californian mining public to this law, a summary of which follows:

"Sec. 5. That the Secretary of the Interior be, and he hereby is, authorized to adjust, liquidate, and pay such net losses as have been suffered by any person, firm, or corporation by reason of producing or preparing to produce, either manganese, chrome, pyrites, or tungsten in compliance with the request or demand of the Department of the Interior, the War Industries Board, the War Trade Board, the Shipping Board, or the Emergency Fleet Corporation to supply the urgent needs of the Nation in the prosecution of the War. . . .

The said Secretary shall make such adjustments and payments in each case as he shall determine to be just and equitable; that the decision of said Secretary shall be conclusive and final, subject to the limitations hereinafter provided. . . . and provided further that said Secretary shall consider, approve, and dispose of only such claims as shall be made hereunder and filed with the Department of the Interior within three months from and after the approval of this act; and provided further, that no claims shall be paid unless it shall appear to the satisfaction of said Secretary that moneys were invested or obligations were incurred subsequent to April 6, 1917, and prior to November 12, 1918, in a legitimate attempt to produce either manganese, chrome, pyrites, or tungsten for the needs of the Nation for the prosecution of the War, and that no profits of any kind shall be included in the allowance of any claims, and that no investment for merely speculative purposes shall be recognized in any manner by said Secretary; and provided further, that the settlement of any claim arising under the provisions of this section shall not bar the United States Government through any of its duly authorized agencies, or any committee of Congress hereafter duly appointed, from the right of review of such settlement, nor the right to recover any money paid by the Government to any party under and by virtue of the provisions of this section, if the Government has been defrauded, and the right of recovery in all such cases shall extend to the executors, administrators, heirs, and assigns of any party. . . .

That nothing in this section shall be construed to confer jurisdiction upon any court to entertain a suit against the United States; provided further, that in determining the net losses of any claimant the Secretary of the Interior shall, among other things, take into consideration and charge to the claimant the then market value of any ores or minerals on hand belonging to the claimant, and also the salvage or usable value of any machinery or other appliances which may be claimed was purchased to equip said mine for the purpose of complying with the request or demand of the agencies of the Government above mentioned in the manner aforesaid."

Claims must be filed with the Secretary of Interior, before June 3, 1919.

Mining Decisions

Mining Claim—Innocent Purchaser

Persons who purchased a mining claim in good faith and for valuable consideration are not responsible for an accounting to one who had rights as against the former owner and vendor under a grubstake agreement.

Kimball v. Superior Court (California), 177 Pacific, 488. December 23, 1918.

Possessory Actions to Recover Mining Claims—Rule

In possessory actions to recover unpatented mining claims, the rule that usually prevails in ejectment cases, that plaintiff must recover on strength of his own title and not on the weakness of his adversaries', does not apply. In such actions the better title prevails.

Oroville International Salt Co. v. Rayburn (Washington), 176 Pacific, 14. November 13, 1918.

Extra-Lateral Right—Narrow and Undulating Veins

A miner in following his vein extra-laterally is not limited in his operations to the exact area within the walls of the vein where the same narrows down to a width which would make working impracticable, or to the exact course of the vein where the same is undulating in its course and economical mining requires straight drifts. Congress, in granting to the locator the exclusive right of possession and enjoyment of all veins, lodes, and ledges throughout their entire depth, did not exclude narrow or undulating veins, and the word 'enjoyment' must be given such a construction as will make the grant effective, even if it involves widening of the drift beyond the vein-walls to make mining of the vein possible. The surface owner of the claims beneath which such extra-lateral rights of adjoining claims extend holds his title subject to this right of the adjoining claim-owners.

Twenty-One Mining Co. v. Original Sixteen to One Mine, Inc. (California), U. S. Circuit Court of Appeals Decision dated February 3, 1919. Not yet reported.

Improvements on Claim—Pass to Re-locator

When the locator of a mill-site ceases, by reason of abandonment or forfeiture due to non-performance of assessment work, to be the owner of the vein or lode, the right to the associated mill-site is ended also. A re-locator of the claims, after such a forfeiture, obtains the right to possession and use of any buildings or improvements which had been so affixed to the land by the original locator as to become a part of it. The original locator has no time after forfeiture within which he may lawfully remove such fixtures. Consequently he cannot enjoin the re-locator from disposing of them as he sees fit. The estate acquired by a perfected mining location (or re-location) has the attributes of a fee-title so long as the requirements of law with reference to continued development are satisfied.

Watterson v. Cruse (California), 176 Pacific, 870. December 7, 1918.

Excess Claim—Adverse Location Thereon

Where public mineral land is open to location at the time a claim is initiated, the location is valid, though the land is excess ground within staked boundaries of another excessive claim, and though the persons initiating the new location had knowledge thereof. Every competent locator has the right to initiate a lawful claim to unoccupied public land by a peaceable adverse entry upon it while it is in the posession of those who have no superior right to acquire title or hold possession. Generally, where a claim is excessive in length, the claim is valid if the error is innocently made, but the excess is void.

Nelson v. Smith (Nevada), 176 Pacific, 261. December 4, 1918.

Company Reports

ARIZONA COPPER CO.

Property: mines, mills, and smelter at Clifton and Morenci, Arizona.

Operating Official: Norman Carmichael, general manager.

Financial Statement: during tho year ended September 30, 1918, sales of copper realized £2,085,112 ($10,008,000). Operations, etc., cost £1,573,445 ($7,540,000). After paying dividends, interest on debentures, etc., the balance carried forward was £60,121, against £13,738 from 1917.

Dividends: preferred shareholders received £2374, and preferred stockholders £22,157; and ordinary shares £227,984 ($1,094,000).

Development: work was curtailed during the year on account of lack of men, but reserves in the Coronado, King, and Pyramid mines were increased. This is milling ore carrying 2% copper. Ground east of the Coronado adit is being drilled to 700 and 1000 ft. depth, but the only mineral is finely-disseminated primary pyrite of low value. The manganese mine a mile from Clifton was opened by 1311 ft. of work, revealing 48,000 tons of 12% Mn ore. This is too low grade for present methods of treatment.

Production: the 11 mines yielded 41,357 tons of smelting (6.38%) and 1,054,211 tons of concentrating ore (2.338%), a total of 1,095,568 tons.

The mills at Clifton and Morenci gave the following results.

Mill	Tons	Copper %	Oxide %	Recovery %
Clifton	113,257	2.13	0.49	71.25
Morenci	1,049,118	2.36	0.35	71.63

Deister tables replaced old vanners at the Clifton plant, and changes were made in the flotation department. At Morenci, the grinding department was improved. Iron balls replaced pebbles in the mills; 12 Allen cones are used for thickening the mill-feed; 12 Dorr classifiers are in close-circuit with Hardinge mills; 8 more Callow cells and several large Dorr thickeners were added. The old crushing plant has been arranged as a sampling and testing mill of 400 tons capacity. It will be used for experimental work on the low-grade ores developed.

The smelter reduced 216,336 tons, 3 furnaces averaging 390 tons each daily. A number of economical improvements were made. The output of copper was 40,468,000 lb., a decrease of about 2,000,000 lb. when compared with 1917.

TECK-HUGHES GOLD MINES, LTD.

Property: gold mine and mill in the Kirkland Lake district, Ontario.

Operating Official: D. L. H. Forbes, general superintendent.

Financial Statement: the gross income during the year ended August 31, 1918, was $107,280. The deficit on operations was $152,415, including interest and discount on bonds, $48,157. The balance at debit is $407,830.

Development: up to July, when the mine was closed on account of labor shortage and cost of supplies, 2540 ft. of work was done in the period under review. The opening of No. 3 vein on No. 4 and 5 levels was the most important work.

Production: the mill treated 15,879 tons of $7.87 ore. On account of unavoidable dilution of waste rock the grade was lower than cut samples. The output in November was 1826 tons of $8.99 ore.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

PRESERVATION OF HOT-WATER SUPPLY-PIPE

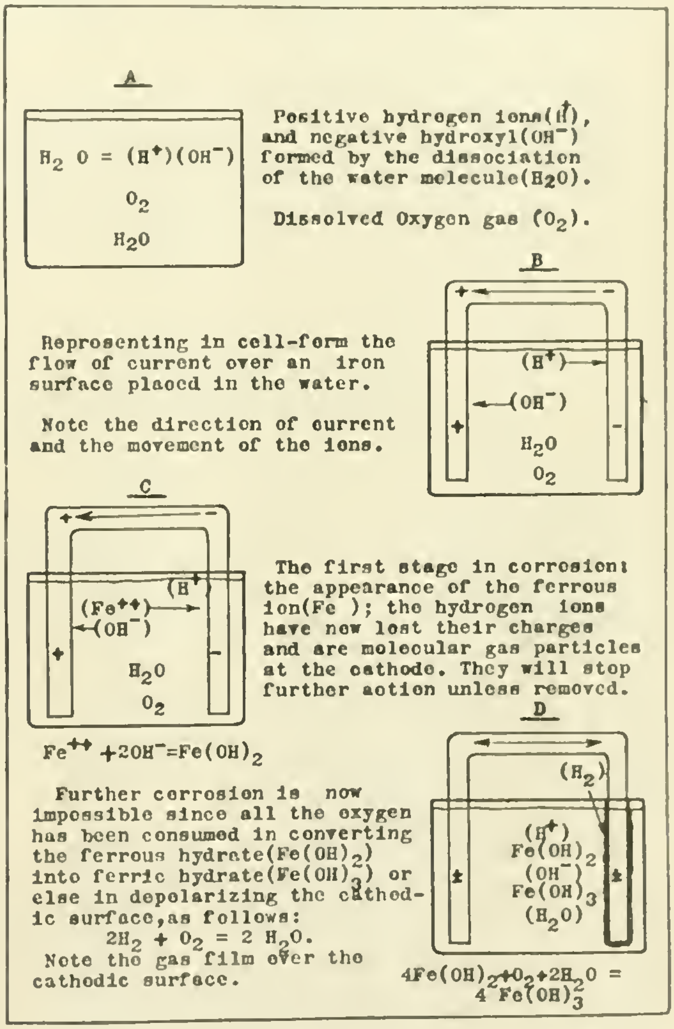
By F. N. Speller* and R. G. Knowland

†The principles involved in the corrosion of iron and steel have been so frequently discussed during the last few years and so clearly enunciated by various writers that a further attempt may seem a little unnecessary. That the problem is not yet generally understood, however, is apparent from the tendency of some writers to confuse many of its essential facts. Such a confusion is not warranted in view of our present knowledge of the mechanism of corrosion and of the factors controlling it. There are a few broad simple principles applying to every case of corrosion and these will be briefly discussed with particular reference to hot-water supply systems.

With reference to corrosion it is possible to classify any particular water under one of two types which may be distinguished by the terms 'active' and 'inactive'. The quality of activity is not primarily dependent upon the acid, alkaline, or neutral condition of a water; but rather upon certain dissolved substances, which exert a modifying influence upon the universal tendency of even the purest water to initiate the corrosion process. This inherent tendency of pure water to attack metal may be greatly aided in those cases where dissolved gases exist in the liquid; and under such conditions the term 'active' typifies its corrosive qualities. An inactive water is one that is not able to promote in any marked degree the corrosion of iron. The sharp boundary between the behavior of these two types of water furnishes a sufficient reason for thus distinctively classifying them. It is a simple matter to demonstrate the fact that an inactive water, after a few minutes aeration, becomes capable of great damage to iron. Fig. 1 shows the steps in corrosion.

By keeping hot water under pressure in contact with a large surface of iron for sufficient time it is possible to remove and 'fix' the oxygen. It is this process of fixing the O that renders water practically inactive or non-corrosive. A successful adaptation of this method is shown in Fig. 2 and 3. The deactivator or treating tank, consists of a Gurney coal-fired heater, a treating and storage tank, and a filter as shown by Fig. 2. The tank was built with a 42-in. flanged head, thus permitting easy packing of the Cambridge metal-lath with which the tank was filled in horizontal layers from bottom to top. In circulation, as the arrows indicate, the water passes from the heater up into the deactivating tank, where it makes contact with the sheet-metal at a high temperature. It moves through this slowly as cooling currents or water from the cold supply urge it, and back into the heater or off through the building supply-line.

The hot-water house supply-pipe leaves the tank at the top and passes to the filter, part of its contents being shunted off through a coil in the filter-bed. A constant circulation of hot water in this coil makes it impossible for the filter to reach a temperature notably lower than that in the deactivating tank itself. Through a four-way valve at the top of the filter, the water for circulation in the building system passes into the space above the filter bed and down through the sand into a chamber at the bottom. In this passage, the rust formed in the deactivation of the water is wholly removed. The building supply is withdrawn through the vertical pipe in the centre of the filter, while the gravity return-line entering at the bottom provides for a continuous circulation of water. It is thus apparent that we have three complete and independent systems of circulation: (1) the one between the heater and tank, (2) that between the filter and tank for keeping the former hot, and (3) the building and filter system. This installation was highly successful, whereas previously troubles were many and expensive



$H_2\ O = (H^+)(OH^-)$

Positive hydrogen ions(H^+), and negative hydroxyl(OH^-) formed by the dissociation of the water molecule(H_2O).

Dissolved Oxygen gas (O_2).

Representing in cell-form the flow of current over an iron surface placed in the water.

Note the direction of current and the movement of the ions.

The first stage in corrosion: the appearance of the ferrous ion(Fe); the hydrogen ions have now lost their charges and are molecular gas particles at the cathode. They will stop further action unless removed.

$Fe^{++} + 2OH^- = Fe(OH)_2$

Further corrosion is now impossible since all the oxygen has been consumed in converting the ferrous hydrate($Fe(OH)_2$) into ferric hydrate($Fe(OH)_3$) or else in depolarizing the cathodic surface, as follows:

$$2H_2 + O_2 = 2\ H_2O.$$

Note the gas film over the cathodic surface.

$4Fe(OH)_2 + O_2 + 2H_2O = 4\ Fe(OH)_3$

FIG. 1. THE ELECTRO-CHEMICAL MECHANISM OF CORROSION.

*Metallurgical engineer, National Tube Co., Pittsburgh, Pennsylvania.

†Abstract of paper prepared for the American Society of Heating and Ventilating Engineers, New York.

A notable instance of the successful treatment of hot water was at the Irene Kaufman Settlement. Pipes were laid on November 22, 1916. On December 24, 1917, the wrought-iron and steel pipe was found to be practically uncorroded; but in duplicate pipes in part of the same hot-water system, unprotected by the deoxidizer, there had been perforation by corrosion. On January 3, 1919 or 2 years and 42 days service the pipes in the deactivated hot-water line were again observed, and found to be so good that it was decided to continue the test for at least another year. The pipes showed the same soft black coating as before, but there was no evidence of pitting, even where the steel pipe was in contact with a brass union, a condition favorable to rapid corrosion by electrolytic action.

STATUS OF EMPLOYMENT IN UNITED STATES

The U. S. Employment Service has further extended the scope of its work by the establishment of two new zone offices of the professional and special section, in Philadelphia (1518 Walnut street) and Boston (16 Tremont street), and it plans to establish other offices of this section in the near future. The new offices are in addition to the two main offices at New York (16 East 42nd street) and Chicago (62 East Adams street), and will serve the particular zones in which they are.

During the eight weeks ended February 22, the Service received 1,090,124 applications from men and women for jobs. Of this number, 930,029 were referred to opportunities and 679,513 were reported placed in employment. The difference between the number referred to places and the number reported placed is due in a large measure to the failure either of the employee or employer to send in their return cards. Unless these are received, the Service has no record of whether the prospect has received employment or not.

COMMERCIAL PARAGRAPHS

Marine machinery and accessories—steam or gasoline—are described and illustrated in the 104-page catalogue—No. 19—of the **Marine Iron Works** of Chicago.

Walter Fitch, Jr., mining contractor of Eureka, Utah, is sinking two shafts, 16 by 22 ft. and 1200 ft. deep, and driving several thousand feet of tunnels, 7 by 12 ft., for the Susquehanna Collieries Co. in Pennsylvania.

The firm of **Woods, Huddart & Gunn**, 444 Market street, San Francisco, has been incorporated under the new name of Gunn, Carle & Co. Iron and steel products, electric furnaces, cranes, trucks, etc., are supplied, also fluorspar is purchased.

Crucibles, cupels, muffles, and scorifiers, as made by the **Denver Fire Clay Co.**, are the subject of Bulletin 100 of this firm. Capacity, sizes, and prices are given. The company has been manufacturing these clay articles for 40 years. Notes are also appended on laboratory crushers and the Case oil-fired furnace—1, 2, or 3-muffle design. Another bulletin deals with fire-brick, fire-clay, and metallurgical tile.

The Powdered Coal Engineering & Equipment Co. of Chicago announces the following: Capt. A. U. Wetherbee, who recently received his discharge from the Chemical Warfare Branch of the Service, and who was formerly chief engineer and assistant works manager of the Niagara Alkali Co., has accepted a position as chief mechanical engineer, and C. C. Wallace, formerly manager of loading of munitions section of the Stenotype Co., Indianapolis, Indiana, is now director of development and service.

John Herman, well-known assayer and chemist of 514 South Los Angeles street, Los Angeles, has equipped a mill for commercial grinding of both coarse and fine at 55th and Alameda streets. It has a capacity of about 40 tons per day, and orders for the grinding of ores of all kinds are solicited. The Herman screening ball-mill is used. Eventually a complete ore-testing plant will be established, including concentration, oil flotation, amalgamation, and cyanidation. Work on this section of the plant is now under way. Herman's slogan. "I do not guarantee satisfaction—I guarantee accuracy," which has been a feature of his assaying, will be adhered to in this new plant.

C. W. Johnson has been appointed assistant manager of works for the **Westinghouse Electric & Manufacturing Co.** After graduating from the Ohio State University he entered the employ of the Steel Motor Co. of Johnstown. A year later he became associated with the Bullock Electric Co., of Cincinnati, Ohio, and in 1904 was made superintendent of the Allis Chalmers Bullock, Ltd., of Montreal, Canada. In 1907 he entered the employ of the Westinghouse company, later being promoted to general superintendent, in which capacity he has served until his recent appointment. Mr. Johnson is a member of the American Society of Mechanical Engineers, American Institute of Mining Engineers, and Engineers' Society of Western Pennsylvania.

The war-time regulations requiring licenses for the purchase, possession, and use of explosives for reclaiming land, stump blasting, ditching, and other agricultural purposes were revoked on March 15, by the Interior Department. The only qualification is that this revocation does not allow enemy aliens or subjects of a country allied with an enemy of the United States to manufacture, purchase, or sell, use, or possess explosives at any time. This letting-up in the regulations was recommended by Van. H. Manning, Director of the U. S. Bureau of Mines, who has charge of the enforcement of the act, and for the reason that the public safety does not longer require such close regulation. It will be of interest to all farmers and those engaged in reclamation work.

EDITORIAL

ON the way to Vancouver and back the present writer had the pleasure of reading two issues of the 'Oregonian', the paper that has made Portland famous. It was a keen delight to read the editorials in the 'Oregonian' and to note the intelligent handling of the world's news. San Francisco suffers more than it knows from a daily press that is the poorest and meanest in the English language. The Hearst infliction is bad enough, but why have we nothing better?

HIGHER taxes await the citizen. The War Revenue Bill signed by the President immediately after he landed at Boston puts into operation the machinery for collecting $6,000,000,000 of taxes this year. The things affected by this taxation include necessaries as well as luxuries. We need not be appalled by the prospect of paying for a successful war but we must discipline ourselves into habits of thrift. We are an extraordinarily extravagant people, wasteful in ways that shame the democratic ideal.

DIVIDENDS paid by the gold-mining companies of the Rand amounted to £5,330,966 in 1918, as compared with £6,556,188 in 1917 and £8,073,436 in 1914. The yield of distributable profit was the lowest since 1905, in which year the tonnage treated was 11,160,422 and the average yield $9 per ton, as against 24,922,763 tons averaging $6.70 in 1918. In 1918 the Central Rand Methuselah is feeling his age. His friends asserted that he would live forever, disregarding the testimony of the truthful tombstone.

MUCH good will come from such public debates as the one at Boston, on March 19, between Senator Lodge and President Lowell of Harvard. Such debates, if properly reported, serve as a means of educating not only those present but the much larger number that read the proceedings in their morning paper. The two distinguished speakers at Boston performed a public service. We venture to refer to Senator Lodge's objection to allowing "our sons to fight the battles of all the nations of the world." This elicited both applause and dissent. As phrased, it should provoke dissent; but if the Senator meant to appeal to the idea of national detachment from foreign quarrels, he was ignoring the lesson so recently taught by the War in which technically we are still engaged. It is certain that any future European war will again be a general battle of the nations; the world has grown small; if one starts to fight, the others are drawn into the melée. Europe and America are too close now to refuse to concern themselves with each other's affairs. If our idea of American isolation had not been taken seriously by Germany, the world would have been saved an untold sacrifice of men and money, of homes and happiness. Whether we like it or not, we have become the neighbors of the European countries and we must take our part now in helping them to arrange their quarrels and in joining them in an effort to prevent another Armageddon, lest we be drawn again into a maelstrom of blood and crime.

RAFAEL NIETTO, the Mexican Minister of Finance, is said to be on his way to Mexico City, after a visit to New York, where he negotiated for a loan from Mr. J. P. Morgan, representing a group of British, French, and American bankers willing to finance Señor Carranza's government on certain conditions, the exact nature of which Señor Nietto will now be able to communicate himself to the President of Mexico. These conditions include evidence of a willingness to pay at least some of the interest due, and over-due, on previous foreign loans incurred by Mexico; also this group of bankers shall control the handling of the new funds to be raised by them, and the Mexican government shall furnish evidence that the country is returning to the normal of peaceful order. It is reported that President Carranza has invited Señor José Ives Limantour to return from France and to resume his former position as Minister of Finance. This is good news, so far as it goes. Evidently Carranza recognizes the fact that he cannot get the money he needs unless he is friendly to the United States and gives assurances that legitimate industry, foreign and domestic, will be protected against brigandage, his own included.

AMERICAN engineers and capital have been particularly successful in their exploitation of gold properties in Korea, or Chosen, as that country is officially styled. We refer especially to the profitable results of the Oriental Consolidated and Seoul mining companies, with which the names of Henry C. Perkins and H. H. Collbran respectively are linked. In this issue will be found an excellent review of the operations of the first named company, by Messrs. H. J. Evans and K. F. Hoefle. We are glad to add that the article was well written, needing little editing, and containing just the essential points worth reading. Since 1896, when operations commenced, the Oriental Consolidated has treated 4,766,270 tons of ore, valued at $29,423,235, from which $7,938,645 was distributed among shareholders as dividends. The mines and mills are scattered over a fairly large concession, necessitating the use of different methods of mining, but costs are fairly uniform. The ore is comparatively low-grade, but its metallurgy is not difficult, and extraction is high. The native labor problem has been solved without serious perplexities, mainly by a close study of the Korean adaptability and industry. In regard to the reported breach between Chosen and Japan, we were told this week by a reliable informant that the Korean is better in every way if under a moderate restraint by others; but perhaps he does not think so himself.

ACCORDING to the law of the Transvaal a mining company has to furnish reasons for ceasing operations, on pain of forfeiting its rights. We note that the Government Mining Engineer, Sir Robert Kotze, has approved of the closing down of the Bantjes mine and has analyzed the conditions justifying such action by the British company controlling the enterprise. Recent development work underground has failed to uncover fresh reserves of ore, that is, of gold-bearing conglomerate sufficiently rich to be exploited profitably. The ore-reserves have been steadily depleted during recent years without the adding of fresh resources adequate to supply the mill, which has a capacity of 360,000 tons per annum. The total cost of operations has risen by reason of the decreased efficiency of labor, from 12.4 to 10.3 tons per month per native laborer; likewise skilled white labor yields only 1.17 fathoms of ore stoped per shift in 1918 as against 1.79 tons in 1916. Recovery in the mill has decreased from 29½ shillings per ton in 1912 to 22¼ shillings in 1917. This is due not only to the declining grade of the ore blocked out, falling from 7.6 to 6 dwt. of gold per ton, but also to the increased admixture of waste-rock. In the nine years to 1914 the company earned a total profit of £202,500, or £22,500 per annum, as against a loss of £30,500 during the succeeding three years. The Government Mining Engineer appears not to state definitely that the lode has become impoverished in depth, but that evidently is the fact.

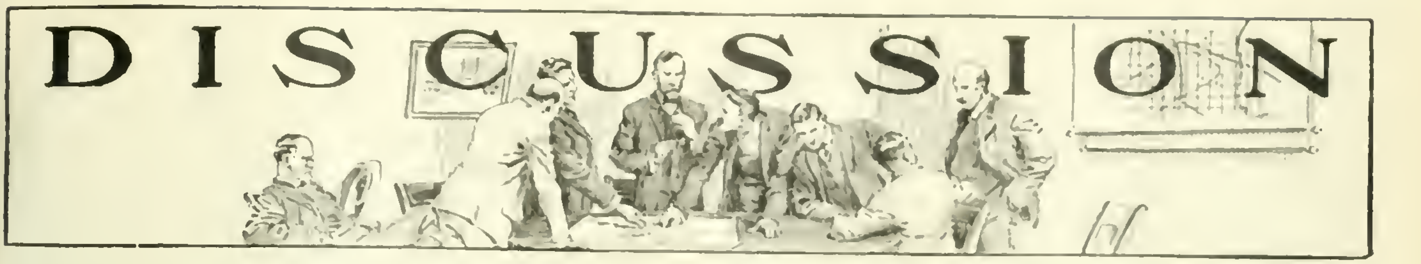
The Colorado Pitchblende Company

In our issue of December 28 we criticized the prospectus of the Colorado Pitchblende Company, an enterprise organized to exploit fluorspar deposits near Jimtown, in Boulder county, Colorado. These veins of fluorspar have been found to contain pitchblende, an oxide of uranium commonly associated with the occurrence of radium and therefore affording opportunity for embellishing a prospectus with pseudo-scientific statements. The public was told that examinations made by scientific and technical men had "tested and proved the ore," of which there was 20,000,000 tons "worth $85 per ton," thus representing $1,700,000,000, owned by a company capitalized for only $100,000 divided into two million shares, which were offered at $2 apiece. Every $500 of 'investment' would earn $100,000 per annum, it was asserted by the promoters. All of which was deeply interesting, if true. It did not appear true, if experience was a safe guide in such matters. Twenty million tons of ore is a quantity not easily "tested and proved." It is not usual to sell for $2 anything that will earn $400 per annum. The prospectus provoked objection from the Boulder County Metal Mining Association and the Boulder Commercial Association, which appointed a committee of investigation headed by Mr. R. D. George, State Geologist of Colorado, and Dr. J. B. Ekeley, professor of chemistry in the State University. The committee reported unfavorably, but this did not abate the impetuosity of the promoters, who then insisted upon an unbiased investigation by one or more of Denver's civic organizations, as related by our Colorado correspondent in our issue of January 4. The word 'unbiased' is used advisedly, because the promoters, Mr. J. F. Barnhill and his associates, imputed the criticism of their stock-selling scheme to "the activities of certain enemy aliens and pro-German influences, which have prior to, during, and subsequent to our war with Germany been continuously brought to bear against legitimate enterprises in this country for the benefit of certain corporations and individuals friendly to our enemies." They mentioned the names of several Germans connected with a radium company, but not content with that they impugned the good faith and patriotism of the State Geologist and others connected with the Tungsten Products Company, as also of Mr. S. C. Lind, of the U. S. Bureau of Mines, and of Mr. R. W. Gordon, of the Stearns-Roger Manufacturing Company. Messrs. George, Lind, and Gordon need no certificate of good citizenship from us or anybody else. The attack on them is mentioned as one of the humors of the controversy. To return to our story. When the matter was brought to the attention of the mining fraternity in Denver, it was arranged by the mining bureau of the Civic and Commercial Association to start an independent enquiry. Mr. James M. McClave was selected to make an examination, at the expense of the promoters of the Colorado Pitchblende Company, and they agreed to abide by the report. At the same time the Manufacturers Association of Colorado appointed Mr. M. S. MacCarthy to make a similar and separate investigation, also at the expense of the promoters. Both Messrs. McClave and MacCarthy are mining engineers of good repute in Colorado. To the surprise of the mining bureau of the Civic Association, if not to that of the Manufacturers Association, the reports of these two engineers were much alike and both of them were favorable. Thus the gentlemen whose examinations were expected to check the stock-selling operations of the promoters furnished ammunition for the furtherance of their campaign. However, the mining bureau of the Civic Association was not satisfied with the reports and that may have been the reason why it withheld publication of Mr. McClave's report until the Colorado Pitchblende Company brought suit on February 12 in the District Court and filed a complaint in which charges of conspiracy and German influence were made against the Civic Association. In reply, the secretary of the Association stated that the delay was due to the need for studying and analyzing the report, which would be issued—as it was a few days later—with the results of their further enquiry into the commercial phase of the enterprise. The Association's report is published on another page. It appears to be a reasonable and intelligent analysis of the facts. We are inclined to give it weight because it is signed by two engineers whom we know: Mr. Richard A. Parker, the chairman of the Bureau, scarcely needs an introduction to our readers as an honored member of our profession; Mr. George A. Stahl is manager of the Vindicator mine at Cripple Creek and is known as a man of high character. We may add that this last report, or analysis of the business, was not published by the Manufacturers Association, for a reason not difficult to guess: the desire not to discourage local industry. With such a desire we sympathize, up to a point, namely, until it transgresses right dealing with the public. The whole truth about this affair has not yet been disclosed, but we give the facts as we know them at this time. The original prospectus was open to condemnation on account of its wild statements. We regret that the U. S. Bureau of Mines should have become involved through the opinion given by Dr. C. E. Scholl, who forecasted a profit of $45 per ton on 20,000,000 tons of ore. The promoters made the most of this statement by "a chemist of international reputation." A chemist's appraisal of a mine is usually futile; he has rarely had the experience enabling him either to make a correct diagnosis of an ore deposit or an accurate estimate of the quantity and quality of ore available; to do that a mining engineer is required. As a matter of fact, the exploiting and marketing of fluorspar, the recovery of the pitchblende, and the extraction of the radium are matters outside the ken of common experience; all of them call for careful study and thorough scrutiny, such as has been given to them in the later stages of the affair, but not at its inception, when the local press was filled with glaring promises of sudden wealth. Dr. Scholl is not now with the U. S. Bureau of Mines, but he is described in the prospectus as having been "associated with Dr. Lind at the Government radium plant in Denver." Moreover, Dr. Lind, the acting chief of the Rare Metals division of the U. S. Bureau of Mines, was dragged into the controversy through the fact that the recognition of the pitchblende was made in the laboratory of the Experiment Station of which he is superintendent, and he himself stated that the sample of galena concentrate contained "over 2%" of uranium oxide. Later he discounted the commercial significance of this statement by explaining that the sample represented a concentration in the ratio of at least 1200 : 1—whereat the friends of the promoters called him a bold bad man. After the reports of Messrs. McClave and MacCarthy were published, with their respective estimates of a profit of $11.85 and $9.14 per ton on a 1000 tons daily output, the promoters resumed their solicitation of subscriptions for stock, by means of full page advertisements, and, using the estimates of the two engineers announced $3,290,400 as the net potential annual profit. They are justified in doing so, for the responsibility now lies on the shoulders of Messrs. McClave and MacCarthy, more particularly Mr MacCarthy, who states in his report that he had made "no attempt to show the maximum profits which might be expected from operation, but, on the contrary, the lowest grades of ores have been selected and maximum factors of safety and highest costs applied thereto for the purpose, if possible, of arriving at the minimum profits to be expected under the several conditions of operation and production established." This seems to us to detract from the value of his report. If it is based upon the 'selection' of ore, instead of accurate sampling, it stands upon a dangerous foundation. On what principle was the selection made and who was responsible for the selection? Advertisements appearing more than ten days ago state that the 100 ton mill will be in full operation "within ten days," so that the controversy should be settled decisively ere long by the logic of events. It is claimed that 5000 tons of ore is ready for treatment and that this will "net over $50,000 in 50 days." *Qui vivra, verra.* Meanwhile we commend the action taken by the Civic Association and advise our readers to study the statement they have issued. It is a good example of the way in which such projects should be analyzed.

The Vancouver Convention

The British Columbia Chamber of Mines, co-operating with its friends at Seattle, Portland, and Spokane, organized the International Mining Convention which met at Vancouver on March 17 and 18. It was a most successful affair, more than 600 delegates and representatives attending the meetings; it was well organized, and the program was so arranged as to include subjects interesting to the various types of men present, the prospector and the operator, the promoter and the engineer of mines. From the opening speech of Mr. A. M. Whiteside, the president of the British Columbia Chamber of Mines, to the closing words of Mr. Maurice D. Leehey, the toastmaster at the banquet, there was evident an Anglo-American friendliness that fully justified the title "International." Every reference made by successive speakers to the establishment of good-will between those living on the two sides of the unfortified frontier between Canada and the United States evoked instant applause. In that spirit the proceedings were conducted and with that spirit the delegates dispersed homeward, determined to attend the next similar occasion, which will be in February next year, when Seattle will act as host to this neighborly gathering of mining men. It is expected that Spokane will take its turn the year after, and that henceforward these three north-western mining centres—Vancouver, Seattle, and Spokane—in rotation will summon the mining fraternity in annual conclave. Mr.

William Sloan, the Minister of Mines of British Columbia, welcomed the delegates in an interesting speech full of good sense and sane optimism. He was able to report healthy progress in the mining of the Province, an increase of production, and an expansion of activity. His government had expended $207,523 in assisting mining, more particularly in building 98 miles of roads and 75 miles of trails, besides repairing 437 miles of roads and 420 miles of trails. He made the important statement that there was sufficient iron ore proved in British Columbia to supply a blast-furnace plant capable of yielding 250 to 300 tons of pig-iron per day. This served as a text for an enthusiastic speech delivered at the banquet by Mr. M. J. Carrigan, of Seattle, who laid emphasis upon the paramount importance of this statement, as forecasting the establishment of an iron and steel industry on the Pacific Coast, thereby aiding every manufacture, more particularly that of ship-building. He recited a long list of iron deposits on the Coast and laid stress on the fact that the hope of an iron and steel industry lies in British Columbia on account of its abundant resources in coking-coal. We expect to hear more concerning this vital matter at an early date. A bonus of $3 per ton is offered on iron produced from British Columbian ores. The Minister of Mines said that the 'wild-cat' was not encouraged in the Province, but the Government aimed to encourage the introduction of new capital. As our readers are aware, most of the big metal mines of British Columbia are operated by American companies, such as the Granby Consolidated, the Britannia, Canada Copper Corporation, Hedley, and the newest gold mine—the Belmont, on Surf Inlet, which is owned by the Tonopah Belmont company and last year came into production with an output of a million dollars. At the luncheon, following the first session, 'Industrial Welfare Work' was advocated by Lieutenant-Colonel R. W. Leonard, president of the Canadian Institute of Engineers. He was followed by a Mr. Bellinger, a representative of the Y. M. C. A., who spoke with the eloquence of a man who knows his subject and is fired by enthusiasm for good work. In the afternoon a comprehensive account of mining prospects in British Columbia was given seriatim by the District Engineers and their chief, Mr. William Fleet Robertson, the Provincial Mineralogist. It is the duty of each Engineer to investigate the mineral area assigned to his charge and to report progress annually. Each of them was in a position to give exactly the kind of information that the Convention needed and they did it effectively and in succession, beginning with District No. 1 and ending with No. 6. The District Engineers are Messrs. George A. Clothier, John D. Galloway, R. W. Thomson, Philip B. Freeland, A. G. Langley, and William Brewer, the last an old friend of technical journalism and an engineer well known in our South-West. These mineral districts are domains of imperial extent, for British Columbia covers 335,835 square miles; they afford a remarkable diversity of metallic products and a wide scattering of mining activity, but No. 1 District is probably the most attractive because it is traversed, with a part of No. 3 District, from south to north, by the Coast or Alaskan range, whose back-bone of granite is flanked by the schist and other metamorphic rocks in which recent important finds of copper, gold, and silver have been made. Nowhere in the world is there a more attractive field for intelligent prospecting, because this long stretch of mineralized country is penetrated by numerous inlets or sounds, which afford ready access to the very feet of the mountains in which the miner finds the ore. In the evening Mr. T. A. Rickard gave an address on 'Mining as an Investment'. This, and other papers presented at the Convention, will be published in later issues of the 'Mining and Scientific Press'. Next day, Mr. H. W. Lawrie gave a paper on 'Gold'; this was illustrated by excellent diagrams and was highly appreciated by a large audience. The subsequent discussion proved the vital interest of the subject. Mr. Sidney Norman of Spokane, the editor of 'Northwest Mining Truth', made a spirited attack on the smelter monopoly and advocated the Government control of smelters. It is a pity that the other side in this controversy was not represented; the reticence of the representatives of the smelting companies—for several such representatives were present—was, it seems to us, a tactical blunder. We commend the sensible attitude of the Granby Consolidated company, which, by means of the reasoned argument offered in Mr. Valentine Quinn's paper, appealed against unfair taxation. Mention must be made of the discussion on prospecting and the prospector, started by Mr. J. P. McConnell's paper on the subject. The effect of prohibition on mineral exploration engaged sympathetic attention. It was asserted that the prospector will keep ahead of prohibition; he will not flourish in an arid region! Many suggestions were made for the instruction of the prospector in technical matters, but Mr. Brewer, who knows the pioneer of mining better than most of us, insisted that it was vain to teach him and that "no government on earth can do it." That seems contradicted by the good work being done at several of our Western mining-schools where special classes for prospectors are well attended. It is probably true that some of the old-time prospectors are unwilling pupils, but, in a broad way, it is certain that the prospecting of the future will have to be done by men possessed of some measure of scientific knowledge and trained observation. The old haphazard search for minerals will not suffice, now that the more evident exposures of ore have been located and exploited. The eye of science is needed, and it will have to be aided not by the pick alone but by the churn-drill or the diamond-bit. It will be noted that the program was of such scope and variety as to cover the chief interests of a diversified gathering of mining men. For this the Convention owes thanks to Dr. Edwin T. Hodge, who was chairman of the Program Committee, and did much to make the arrangements run smoothly. Two days were devoted to the public sessions and on the third an excursion to the Britannia mine brought the Convention to a close. The success of it augurs well for the meeting at Seattle next year.



Mill-Tests v. Hand-Sampling

The Editor:

Sir—Regarding a certain interesting discussion appearing of late in your columns, it seems to me that this is hardly well named as 'Mill-Tests v. Hand-Sampling'. The issue seems to me rather as to whether mill-tests are necessary or desirable as a supplement to and a check on hand-sampling. I take it that no serious engineer holds that a deposit should be valued without hand-sampling. He may believe that mill-tests are necessary or desirable as above, but not that mill-tests alone should be used. The latter so obviously would mean either that very few points in the deposit should be represented in the sampling (valuing) or that further operation would involve a prohibitive cost.

It is well to remember that the valuing of deposits has frequently to be done with limited facilities and with limited expenditure and many have to be reported upon under circumstances where mill-tests are not feasible. This discussion, therefore, does not cover all cases, but only those where mill-tests are feasible. Applied to such cases, it deals with the importance of mill-tests as compared with, and as supplementary to, hand-sampling; also with the manner in which mill-tests should be utilized, in order to provide the maximum check on hand-sampling, and with the methods of taking the samples.

In all valuing there are three factors essentially to be kept in mind:

(1) To see that each sample correctly represents the actual spot it is taken from; that it does not contain more or less than the proper proportions of the different sorts of mineral composing the ore at that spot. The old trouble of the tendency to get an unduly big proportion of the softer (especially the more friable) mineral, is the most common cause of error. This consideration, in conjunction with (2), should determine the manner in which the actual work of taking the samples must be carried out, including probably the preparation of the faces before sampling.

(2) To take the samples so that—assuming that each sample accurately represents the spot it is taken from—these, taken on the whole, give, with what degree of accuracy is feasible, the value of the faces sampled. This consideration must determine the general plan of the campaign, where the samples shall be taken, the weight of each, the length of strip to each sample (if the sampling be done in strips), the distance apart of the samples, the manner of taking them (by moil or blasting or drilling).

(3) The next points to consider are whether the deposit will all be excavated and whether any other rock (wall-rock, 'horses', etc.) will be excavated with it. The former point does not on the whole affect the grade, it would affect the tonnage, of course. The latter point affects both grade and tonnage. Generally, the former point will be ignored, although it is by no means certain that it should be, as ore is certainly lost by some methods of mining. It is frequently more than compensated by the existence of ore, not in sight at date of valuing, adding to the tonnage. This requires serious consideration. To this matter the engineer must simply apply his experience to a study of the walls. If the mine has been partly worked, he should be able to get valuable data from comparisons of previous records and from study of accessible stopes. Again, if neighboring mines have similar characteristics he ought to be able to secure valuable data regarding this point from them.

The above being the factors, the question arises, can hand-sampling alone—aided, of course, by experience and observation—be relied on to give the results? If not, can mill-tests assist in so doing; and if so, what is the best way in which to apply the mill-tests? It is assumed here that mill-tests are used only as large (bulk) samples, not as metallurgical guides.

(1) and (2) if performed correctly will give the average value of the faces sampled as accurately as is practicable. Whether the said faces are representative of the whole deposit (or of the developed portion of it) is another matter. Sampling results will not decide that point, although study of them in general and in detail may (and probably will) help very materially to obtain a fair judgment on it. It is purely a matter for the engineer to decide as to the interpretation he will place upon the value of the exposed faces as reflecting upon the value of those parts of the deposit some distance from the faces. Anyhow, we can do nothing but sample the exposed faces; the rest is a matter of surmise and judgment, and we must be content with it as such. The likelihood of the value of the exposed faces representing the value of the deposit surrounded by them will, among other things, depend on the reasons that caused the said faces to be in the places they are.

However, having made whatever allowance he thinks fit in this regard, the engineer can take it that, having sampled accurately with regard to factors (1) and (2), he has all the data he can get—so far as sampling is concerned—for his valuation of the deposits as it stands *in situ*.

In any case mill-tests will not assist in settling the factor (3). The only practical test that will assist here is to excavate sufficient ground and watch results. Generally, such a proceeding is quite outside the time and money available for a report. It seems to me, however, that mill-tests may be a most useful check on the results obtained from (1) and (2), more particularly in some deposits (obviously those whose nature render them more open to errors in sampling).

The extent of the mill-tests and the manner of applying them should, of course, depend on the nature of the deposit. In some cases a very few mill-tests might give all the check that is wanted and all that is of practical use. In others, a considerable number might be necessary if the principle of checking by mill-tests is to be safely or consistently utilized. This point (as to the number required) is not one that can be written about. It is purely a matter for individual judgment in each case. Generally speaking, the same might be said concerning the manner of taking the ore for the mill-tests. For ordinary cases the best method seems to me to be to select certain faces—drifts, cross-cuts, winzes, or stopes—selecting these as the ones most representative of the deposit—or the part of the deposit specially in mind—to sample these faces particularly carefully, both as regards the number of points sampled and the actual taking of the samples, and to then take strips—say two feet deep—over the whole area of the faces sampled. The comparison of such bulk-samples with the averages obtained from moiling the faces should give ordinarily about as valuable a check as is obtainable. If the fresh face (two feet back from the original) be also specially carefully sampled, and two face-samplings averaged, the check would be better. In choosing faces for such checking it would seem to me that, if it appeared that the values in the deposit were tending to, so to speak, form a grain in certain directions, faces running across the said 'grain' would constitute better checks than those running with it. This is only applying the principle adopted in cutting strips across vein-formations because these commonly tend to have a 'grain' parallel to the walls. The faces would also be selected as being as closely as possible ones representing the average character of the orebody. In cases where the character of the ore varied in such a way that it was advisable and feasible to obtain different factors of error for the different kinds of ore, they would be selected as being representative of certain portions of the deposit, whether such portions (of varying nature) occurred in large or small masses. For this purpose each face selected would need to be wholly of one kind of ore. Having obtained checks on the sampling of various faces by these means the obvious procedure would be to then correct the results obtained from hand-sampling by the factors of error so discovered. We should have, for the different characters of ore, different factors of error with which to adjust the sampling results, and the adjustments would be applied to the samples according to the character of the ore represented by each. In the event of the different kinds of ore being so mixed that it is impossible to find faces of any length of one character, I would suggest that a number of short lengths of faces of one character could be taken, the strips therefrom be aggregated and the sampling results averaged.

Mr. Morton Webber has put forward a method of checking hand-sampling by means of mill-tests. I cannot say that his method appeals to me, as I understand it. His taking of a bulk-sample from one spot only, this being compared with only two or three hand-samples, is, I believe, insufficient for the purposes of comparison. I submit that it is only by taking a number of hand-samples that a result can be secured for such a comparison. Mr. Webber's method assumes that the two or three hand-samples taken before, intermediate to, and after certain breakings, truly represent the average value of the ore secured by such breaking. This seems to me to be contrary to experience, which indicates that hand-samples individually (taken with care) may accurately represent the actual spot sampled, but do not represent accurately the immediate areas of the faces of ore which they stand for, nor do they even represent accurately an area, say, covering a foot all round the actual sample. A considerable length of face very closely sampled might reasonably be expected, on the law of averages, to fairly accurately represent the value of the ore behind that face to a depth of, say, a foot to two feet. Even this is no certainty, but it is about as much as can reasonably be done to ascertain the factor of error we seek.

I must confess to a considerable doubt on this matter of securing and using factors of error and agree with those who say that the attempt to do it would need great circumspection and judgment, and would, in many hands, introduce a most dangerous element.

My experience has been much more limited than that of Mr. Webber, but so far as it has gone, I know of no deposits where in my opinion his method of dividing the mine up into areas would correctly interpret the facts. If the method is designed to suit variations in the nature of the ore, my experience is that the variation would occur in much too irregular a manner to enable this method to be applied. If the character of the ore is apparently fairly uniform, then I should say that it would be more consistent to average the results of the whole of the hand-samples taken at the places where the bulk-samples are taken, and compare this with the average of the whole of the bulk-samples and establish a general factor of error from this comparison. It may be said that this would result in giving an average result much the same as by Mr. Webber's method of subdivision. In a deposit of no great variation of width it would do so. In cases of great variation it might be far from doing so. In any case, I submit that it would be based on a sounder principle—that of averages. If a sufficient number of bulk-samples were taken in that way, no doubt a fairly correct factor of error could be secured. The greater the number the more accurate would the factor so calculated become. In Mr. Webber's method, supposing in one or more cases the bulk-sampling gave considerably higher results than the hand-sampling, would the calculated factor be added to the values obtained by hand-sampling in that area? To be consistent it should be so.

Personally, I believe that practically all deposits can be better sampled by a number of small samples than by any method of bulk-sampling, which would be within reasonable cost, alone. I believe that bulk-sampling can be used in most, if not all, cases with advantage as a check on the small samples and probably its use may enable factors of error to be obtained that can be applied to the whole of the small samples. In the event of bulk-sampling not being practicable as a check, it may be necessary to take more elaborate care to avoid mistakes in the small samples than if the said check can be used. I believe that where bulk-sampling is used as a check, its method of application must depend entirely on the character of the deposit. A discussion of various methods may, however, give useful ideas in this respect.

In mines that have been worked fairly extensively, if accurate and sufficient records have been kept of treatment results and of mine-sampling and if the methods have been good, the need for mill-tests should disappear. A factor of error should be obtainable from the records. In any case, whether taking bulk-samples or not, all possible information should be obtained from the records, as a further check on sampling results.

In cases where no metallurgical treatment has been done the dumps from development should constitute most useful sources of information, especially if it is possible to identify the ore from various headings. The proper sampling of dumps, of course, implies large samples and brings in again the use of the mill.

With especial regard to the sampling of large low-grade orebodies, I cannot myself see that any special features come into play as compared with the sampling of mines of moderate size. It appears to me generally that, other things being similar, the larger the orebody—or rather the greater the total area of the face that is exposed—the fewer need be the number of samples per unit of area. This simply comes back to the law of averages. Of course, an orebody having variable character of ore, if it is desired to value the different types of ore, would require more samples than would an orebody of equal size and of uniform type of ore.

With regard to the manner of taking the individual samples, whether taken by hammer and moil, by blasting, by drilling (the drillings forming the samples), etc., whether the samples should be taken in the form of parallel sections or at equidistant points, the size of each sample, the distance apart, and so on, it appears to me that no general rule can be laid down. The engineer must decide these points for each case on its merits. In view of the widespread use of the method of cutting parallel sections, I may say that I cannot see any special virtue in the method except where there is reason to suppose a tendency of the values to form 'grains'. Generally speaking, it no doubt suits nearly all vein-formations whose width is small compared with the length and depth. In sampling masses of ore of a schistose or laminated or stratified structure, the method of taking sections across the laminations, etc., would no doubt often be advisable. Certainly one would not take sections along them. Ordinarily in a mass deposit where there is no reason to believe a 'grain' exists, the sampling would more logically be done by taking samples at equidistant spots rather than by parallel sections. The same amount of work should give a more representative result.

The case of valuing deposits where the ore occurs in rich patches (like the quoted plums in a pudding) is often mentioned. It is obviously impossible to value such a deposit accurately by sampling. It cannot be too clearly or often stated that after all sampling is a method only of ascertaining the values of exposed faces. If the faces do not accurately represent the deposit, obviously sampling cannot give the true value of the deposit, even if it gives that of the faces. In such deposits it appears to me that all one can do is to sample the exposed faces by means of small samples taken at short distances apart. Such sampling may be reasonably supposed to indicate the distribution of the rich patches exposed by the faces. These patches can then be sampled with a greater degree of thoroughness, including perhaps some bulk-sampling, and their values estimated separately. The results should give, as closely as work can give it, the value of the faces. Whether the faces truly represent the deposit is another matter. The engineer must either gamble on this or decline the responsibility. The obvious way would be to give the results of the sampling and explain the uncertainty (and the degree thereof) of these truly representing the whole orebody. It is fair to remember in this connection that the faces may indicate a lower value than is really the case. We all know that many mines have turned out better than prospects at one time indicated. All we can do is to value the exposed faces and decide on that whether the deposit is a good mining risk or not.

H. R. Sleeman.

Whim Creek, Western Australia, November 5, 1918.

The Editor:

Sir—I have studied Mr. Sleeman's letter above, and in that part of his letter where he criticizes my 'combination method' of mine sampling, it would seem that he has read my views in a superficial way. For example, he says: "I cannot say that his [Webber's] method appeals to me, as I understand it. His taking of a bulk-sample from one spot only, this being compared with only two or three hand-samples, is, I believe, insufficient for the purpose of comparison. I submit it is only by taking a number of hand-samples that a result can be secured for such a comparison."

Regarding the statement about taking "a bulk-sample from one spot only," if Mr. Sleeman will refer to my contribution more carefully, he will read as follows: "I desire to say that in the examination of large ore deposits, I do not consider a mill-test to be representative individually, but only as a link in a chain of mill-tests supplemented by corrected hand-sampling. . . . I contend that a mill-test from a particular part of a large ore deposit will represent only the particular spot from which the ore has been removed." I further stated that "In the majority of cases, in dealing with the sampling of large low-grade ore deposits the estimation of ore-reserves must be based on hand-sampling. This can be corrected by a series of mill-tests employed for the sole purpose as a sampling error indicator. Once this error is obtained for a given place, the mill-test should terminate. A fresh mill-test should be made elsewhere to obtain the sampling error for another zone."

Where does Mr. Sleeman get his authority for the words "two or three," when I say clearly "a reliable estimate can be made of the local sampling error by obtaining the average of successive sampling of the stope-faces as the ore is removed for a mill-test and comparing this result with the recovery plus the tailing loss. Surely the adjective 'successive' cannot be intelligently taken to mean but 'two or three.' This sort of thing suggests the attempt of an attorney to make a case, rather than the constructive criticism of one engineer on the work of another.

The combination method of sampling a large low-grade deposit was not intended to apply to ordinary size mine examinations. This was clearly pointed out in the original contribution. This method, as will be remembered, was intended for the sampling of great low-grade deposits such as the Alaska Gastineau, Alaska Juneau, and others, where a large sum of money is involved, and where a discrepany of, say, 40 cents per ton between the mine sampling and the mill heads might mean complete financial failure.

Mr. Sleeman states: "I believe that practically all deposits can be better sampled by a number of small samples than by any method of bulk-sampling." I presume by "small samples" he means hand-samples, that is, samples taken by moil or by pneumatic channeler. The Alaska Gastineau case has conclusively proved that hand-sampling alone will not meet the case, nor would a relatively small number of large mill-tests indicate what should be expected from supposed ore-zones considerably remote from the point whence the large mill-test sample came. The mining industry paid about fifteen million dollars to find this out. It was, therefore, a desire to anticipate the recurrence of a similar mistake that led to my combination method, where I divide the area into a large number of small mill-tests, and fall back on corrected hand-sampling and the law of average to sample the intervening spaces in the "chain of mill-tests." The distance between mill-tests, or, in other words, the size of the area or zone over which the mill-test would control the hand-sampling, as I explained, must depend upon the individual case. R. E. Raymond wrote a valuable contribution on this phase of the subject, which appeared in the 'Press' of November 3, 1917.

After the mine has been sampled by this combination method, or in event of the property being sampled during process of development, the further complication would have to be considered of whether all the ore could be mined clean as sampled without dilution from sloughing or the inclusion of 'horses' that escaped sampling. The latent sampling error common to the great majority of ore deposits and the mechanical dilution owing to sloughing are distinct problems, and should be considered separately. In my experience I know of several cases where it was possible to mine the walls clean, but there was a latent sampling error in the moil channeling of the backs and other parts, always resulting in a discrepancy between the average of the sampling and the mill-head.

The title 'Mill-Tests v. Hand-Sampling' has evidently somewhat confused Mr. Sleeman in his criticism of my views; the title is unfortunate. It had its origin in an article I wrote for the issue of July 28, 1917, entitled 'Mill-Tests v. Hand-Sampling in Valuing Mines.' The title was suitable for the original article, which dealt with three important examinations I had conducted. Later valuable contributions emanated, as a result, from E. P. Spalding, R. E. Raymond, Charles Bennett, F. F. Sharpless, and several other engineers, and the original title was continued— no doubt to identify the series. The combination method of sampling that I devised was a utilization of the important merits of both methods in combination, a description of which appeared in the issue of September 29, 1917.

MORTON WEBBER.

New York, March 10.

MANGANESE EXPORTS from Brazil during the 16 years ended with 1917 are shown in the following table, together with the average price in paper milreis (worth about $0.25 in United States currency):

Year	Exports Tons	Average price per ton Milreis	Year	Exports Tons	Average price per ton Milreis
1902	157,295	28.388	1911	173,941	22.279
1903	161,926	20.629	1912	154,870	22.250
1904	208,260	29.086	1913	122,300	22.250
1905	224,377	22.673	1914	183,630	25.485
1906	121,131	22.058	1915	288,671	36.477
1907	236,778	33.828	1916	503,130	58.641
1908	166,122	23.708	1917	532,855	107.503
1909	240,774	23.694	1918	345,877*	117.000
1910	252,958	22.526			

*Tonnage imported into the United States.

When war orders for manganese commenced to be placed in 1915, the price immediately began to rise, but the greatest increase was shown during 1917, when 1916 prices were nearly doubled.—Consular Report.

GOLD-MINING COMPANIES fare under the Revenue Act as follows: Section 304-d—"In the case of any corporation engaged in the mining of gold, the portion of the net income derived from the mining of gold shall be exempt from the tax imposed by this title, and the tax on the remaining portion of the net income shall be the proportion of a tax computed without the benefit of this sub-division which such remaining portion of the net income bears to the entire net income."

MANGANESE MINING has been resumed by four companies at Batesville, Arkansas. Ore of 45% grade is quoted there at 55 cents per unit, equal to $24.75 per ton. From this basis to 50% the rise is 5 cents per unit. It is evident that these centrally-situated deposits can possibly compete with foreign ores.—W. R. Crane in charge of this division of the U. S. Bureau of Mines.

TRANSPORTATION OF MACHINERY TO THE ORIENTAL CONSOLIDATED MINES

The Unsan Mines, Korea

By H. J. EVANS and K. F. HOEFLE

Introduction. The mines operated by the Oriental Consolidated Mining Co. are situated in Unsan, one of the north-western districts of Korea, officially known as Chosen, the small peninsula extending south from Manchuria between the Japan and Yellow seas, now a part of the Japanese empire. The mining concession embraces the entire district, an area of approximately 400 square miles, and is familiarly known as 'the Unsan mines'. As it is the pioneer foreign mining company in the country, a short history of the undertaking may be of interest.

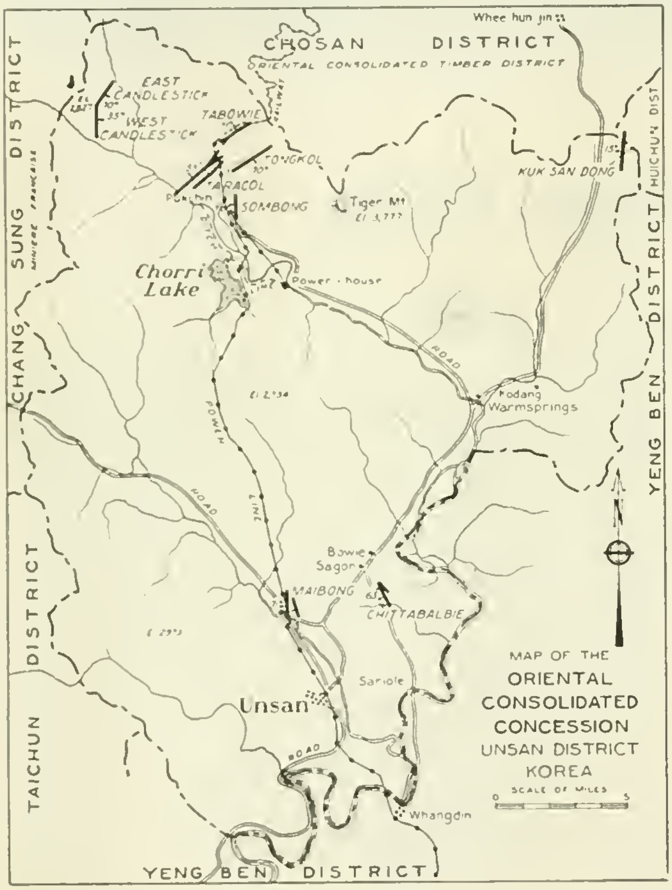
Gold mining along primitive lines had been carried on in Korea for centuries, but not until 1895 was foreign capital enlisted in its development. In that year the Emperor granted permission to James R. Morse, an American business man, to work all the mines in the Unsan magistracy for a royalty of 25% of the net profit. During the following year—1896—passports were issued to engineers to proceed to the mines, and more favorable terms were granted by the Emperor. Some development was started on the richer quartz lodes, and a 10-stamp mill was erected to treat the ore from the Chittabalbie mine.

The concessionaire was again granted an extension of 25 years to the lease, free entry for all supplies, release from the royalty, and exemption from taxes. The Chittabalbie mine proved highly profitable, and the promoters procured sufficient capital to ensure success to the venture. The three companies that were interested in the concession during the years previous to 1901 were merged in that year by Leigh S. J. Hunt, one of the largest holders, and the Oriental Consolidated Mining Co. was formed with a capital of $5,000,000. Under the direction of Henry C. Perkins, now president of the company, the undertaking was carried through the critical stage of its life. During the early exploration of the prospects and erection of reduction works, natural obstacles to progress were so numerous that only men of tenacious character and indomitable courage could have carried the work to completion. The absence of roads, scarcity of timber and fuel, remoteness from civilization and sources of supplies, the absence of skilled labor, the Korean's natural disinclination to work for a foreigner, and the not always veiled opposition of the populace constituted a set of problems that might well have discouraged any group of men. The fact that the pioneers not only merely overcame these troubles, but did it in such a way as to establish the company on the sound basis it enjoys today, at the same time winning the goodwill of the people and maintaining amicable relations with a chaotic and unstable government, deserves more than passing mention. With an original investment of less than $100,000, the company was built up from its own profits, until at one time there were five mills operating with a total of 240 stamps.

Unlike most mineral regions, the community presents the appearance of being an agricultural centre rather than one of gold mining. The country has a delightful climate; all seasons being remarkably agreeable and healthy. The mines are 60 miles distant from the main railway, requiring four hours travel by motor-car to reach them. The connecting highway traverses a wide and matured valley depressed between long low ranges overgrown with an abundance of shrubbery and lonely pines.

General Geology and Ore Deposits. Heavy precipitation, warm summers, and cold winters form an ideal combination of eroding agencies, whose action on the granitic formation give the region a rather high and rugged topographic relief.

The structural features of the geological formation included in this area are comparatively simple. The lodes are typical fissures with filling from 20 to 140 ft. wide, and of unusual vertical persistence. While no detailed study of the entire concession has been made, one formation only has been observed at surface exposures or found in any of the underground workings. This formation has been subjected to intense crushing and faulting. A series of fissures running close to, and more or less parallel with each other, have been developed at various points on the concession, many of them containing substantial orebodies. The following extract, taken from a report made to the company, in 1916, by J. Malcolm Maclaren, concisely describes the formation near the larger mines:



"Two granites differing greatly in age and character, make up the rocks. The older granite, probably Archaean in age—now essentially a gneiss, is the basement rock of the country. Economically, the most important rock is a coarsely-grained grano-diorite which has absorbed a great portion of the older gneiss."

The most prominent lodes are located along the northeastern boundary, near the town of Pukchin. In this section much faulting, subsequent to the period of ore deposition, and the intrusion of dolerite dikes, following the channels of least resistance, are the prominent features noticed in most of the mines. Two parallel fissures, about 500 ft. apart and three miles in length, striking N. 75 E., and one large cross-fracture, striking N. 55 E., with numerous branches of no economic value, on both foot and hanging walls, are of the greatest importance. The later development of a cross-fault displaced the western half of these three lodes about 4000 ft., with a down-throw of possibly 600 ft. The fault-zone is several hundred feet wide, and contains fragments of the disconnected orebody. The dikes, which follow or cross through the veins or along the fault-zone without regularity, vary in thickness from a few inches to 30 ft. On opposite sides of this fault-zone—Tabowie and Taracol—are situated the company's two largest mines. On the Taracol side of the fault, the dike is seldom found in the lode-centre, suggesting much less movement in adjustment of stresses on that side, while in Tabowie mine it follows along or crosses through the ore without rule, and frequently reaches 10 ft. in width. The orebodies occur in the centre and along both walls; the central shoot being the larger and more persistent.

STOPE ON NO. 15 LEVEL OF TABOWIE MINE SHOWING LODE CUT BY THE INTRUSION OF A DOLERITE DIKE

Lode Material and Orebodies. The lode material is quartz containing pyrite, galena, sphalerite, gold, and a small quantity of silver. A predominance of galena is generally accompanied by an increase in gold. The ore is comparatively low-grade, visible gold being rare. Small high-grade pockets do occur in the Taracol mine, some fine specimens having been recently found on the 1230-ft. level. An abundance of graphitic gouge follows along the walls and planes of movement. Graphite in small quantity is distributed through the ore, filling the seams giving the quartz a characteristic banded appearance. The main orebodies appear at or near the junctions, and pitch westward with them. However, substantial oreshoots are found entirely separated from these connections, especially on the hanging-wall side. There is no marked evidence of any secondary enrichment, and the zone of oxidation extends only a short distance below the surface. The ore shows remarkable persistence in depth. An apparently rich zone of secondary sulphides seems to exist between the 10th and 16th levels in the Tabowie mine. The stoping width was uniformly much wider and the value lower above this horizon, while below there was a slight impoverishment. The ends of the orebodies are generally accompanied by large masses of barren quartz, changing to graphitic gouge and altered wall-rock. The present depths of the Tabowie and Taracol mines are 2600 ft. and 1800 ft. respectively. The lowest workings are still in ore.

The Chintui and Nuchadagi mines are on separate orebodies on the same lode, 2000 ft. west of Taracol. Many other lodes within the immediate vicinity have been prospected, but so far only two of these smaller mines—Sambong and Tongkol—situated a short distance south and east of Taracol, have warranted extensive development. The Charabowie mine, near the southern boundary, contains two parallel fissures 80 ft. apart, having the same dip of 70°. Each lode carries an ore-shoot 5 ft. wide and 500 ft. long. Both orebodies pitched at an angle of 45° with the horizon, and persisted to a depth of 1850 ft. before showing any impoverishment. The minerals contained are similar to the other mines. About 80% of the gold content is in a coarse free state. The mine was exhausted and closed during July 1918, after having produced nearly $4,000,000.

The Chittabalbie, in the same locality, the first mine to be operated by the company, yielded much high-grade ore from the oxidized zone near the surface. The company has operated several other mines during the past, all being of similar type.

Mining Methods. The different sizes of the orebodies, the varying strength of the walls, and widely differing physical characteristics, necessitate the adoption in each mine of different methods of mining. Overhead stoping with or without timber is the general practice. Narrow hard veins or weak walls prohibit the use of any more advanced or cheaper methods of extraction.

The Tabowie, Taracol, and Chintui mines, all on different portions of one and the same fissure, require square-setting with medium heavy timber, due to large stoping width, soft walls, and much slipping of the back along the graphitic seams in the quartz.

As a rule, considerable quantities of waste and dike material are mixed with the ore, requiring systematic sorting and elimination of the largest boulders, before the ore can be dumped into the shaft-pockets. Most of the sorting is done in the stopes, and the discard used for filling.

The increased costs of inferior grades of timber and lagging caused the management to consider changes in methods of underground work, whereby the consumption might be reduced. The former practice of running long stopes concentrated together, requiring the changing of many manway and chute-sets, was changed to a more effective and economical method of carrying up as short stope-length as practicable. While the former system enabled the gathering of larger crews and easier supervision, these factors were greatly offset by the high cost to keep them open and safe for the miners.

STOPES AND PILLARS IN KUK SAN DONG MINE

At present, most stopes do not exceed 40 ft. in length, with a chute and manway at each end. The upper portion of one chute is used to convey filling material into the stope from the above level. The results of this new method have been highly gratifying, and the change exemplified by two years of practice enables a stope to be finished in one-third of the former time with greater

THE CHITTABALBIE MINE, THE FIRST TO BE OPERATED BY THE ORIENTAL CONSOLIDATED

GENERAL VIEW SHOWING THE MAIN PORTION OF THE

Left: Mine timber and Fuel yards. The inclined track connects with a narrow-gauge railway, 20 miles long, used to

Right. The river follows the strike of the central fault. On the right bank of the river can be seen the Taracol mine head-frame.

economy. The average stoping width of these mines is about 12 ft., but often extends to 50 ft. or more.

Ore-breaking is done by hand-drilling, using 40% gelignite. All filling is obtained from the development headings—mostly the lower levels. Due to the comparatively low cost of labor, machine-drills have not proved economical for this company, except in shaft-sinking and development headings where rapid progress is desired. Development progresses slowly, requiring almost constant advance of all headings to maintain a moderate ore-reserve. Above is a table showing the footage of work done at each mine during the last fiscal year:

Kind of work	Tabowie	Taracol	Tongkol	Chintui	Charabowie	Maibong	Prospect	Total
Driving	7,675	7,246	2,601	1,473	452	353	294	20,094
Cross-cutting	1,834	1,393	268	516	214	37	16	4,278
Raising	2,597	3,643	918	666	218	130	7	8,179
Winzes	1,062	....	406	205	139	108	216	2,136
Shaft-sinking	80	526	60	104	...	...	...	770
Hoist and pump stations	239	86	26	33	...	...	...	....
Total of each mine	13,487	12,894	4,279	2,997	1,023	628	533	35,841

The various costs at the principal mines are shown in the following table:

Cost per Ton of Ore Mined During Fiscal Year 1918

	Tabowie	Taracol	Chintui	Tongkol	*Charabowie
Tons of ore	128,106	101,617	23,881	8,040	42,028
Miners and timbermen	$0.455	$0.371	$0.413	$1.222	$0.333
Shovelers and trammers	0.067	0.062	0.058	0.184	0.043
Explosives	0.226	0.189	0.163	0.929	0.157

*Calculated for 11 months only

All development and stoping of the ore is done by contract, and the method adopted has been satisfactory to both the company and miners. All the work of an entire level generally is given to one bidder, the contractor agreeing to break, sort, and tram the ore, and timber the various workings on the level for a fixed rate of payment. This system eliminates a great many trivial troubles and disorders. The total costs at the various mines are fairly uniform, except at Tongkol, where the finding of small erratic high-grade pockets increase the costs noticeably.

In the smaller mines the ore can be extracted without the use of much timber, but the other items make their operations expensive.

In accordance with standard mining practice a large reserve of broken ore is held in stopes as well as a month's supply kept on the surface in case of any interruption to the hoisting service.

The company employs 2000 men underground.

MILLING. The company is now operating three stamp-mills: Tabowie, 80 stamps; Taracol, 80 stamps; and Maibong, 40 stamps. The mines supplying ore to these mills are as below:

Mine	Monthly tonnage	Mill delivered to	Number of Stamps
Tabowie	11,000	Tabowie	80
Taracol	8,000	Taracol	
Chintui	2,400	"	80
Tongkol	800	"	
Charabowie	3,300	Maibong	40
Maibong	500		
Total	26,000		200

The design of the plants and process of treatment are similar at the three plants, hence the description will be general.

The ore before being dumped into the mine-pockets is sorted carefully, all waste and large boulders being eliminated, thus providing uniform feed to the crushers. The material is mostly quartz, medium hard, containing about 7% by weight of the sulphides of iron, zinc, and lead.

The ore is trammed to the mills in standard 1½-ton cars, weighed on Fairbanks scales, and dumped on grizzlies with 1¾-in. spacings, and set on a 45° slope. The oversize passes to 10 by 15-in. Blake crushers, which reduce the material to the same size as that passing through the grizzlies to the bin. The bin capacity is sufficient to supply the mills for 36 hours.

A modified Challenge feeder delivers the ore to 1050-

ORIENTAL CONSOLIDATED COMPANY'S PROPERTIES

convey timber to the mines from the forest. On the hillside are the explosives magazines, as outlined by the zig-zag road
mine hoisting plant, and lode-outcrop in the background
and along the opposite hills, the car-line to Tongkol mine. The displacement of the lode along this fault plane is about 3500 feet

lb. stamps arranged in the usual unit of 10 stamps.

Mill Operations for Fiscal Year 1918

	Tabowie	Taracol	Maibong
Number of stamps	80	80	40
Ore crushed, tons	128,106	133,538	42,028
Stamp-duty, tons	4.70	4.87	3.26
Value of ore	$6.56	$5.07	$8.57
Recovery by amalgamation, per cent	44.79	40.01	71.61
Recovery by concentration, per cent	46.14	49.42	18.88
Value of tailing	$0.66	$0.60	$0.68

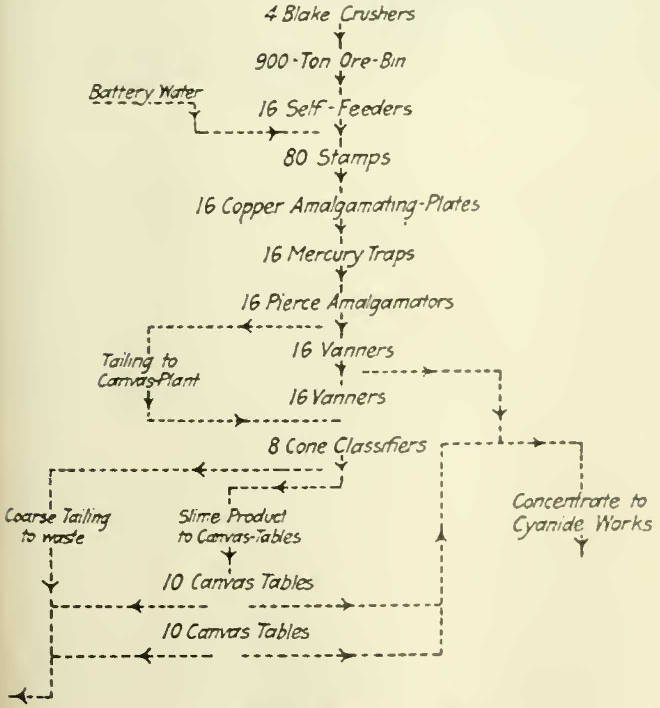
The stamps make 102 drops of 7½ in. per minute. The discharge is 4 in. Punched round hole screens of 26-mesh (diam. 0.038 in.) are used. The mortar-blocks are of concrete. A ½-in. sheet of rubber is placed between the block and the mortar. Two lines of main shafting are carried on the floor timber beneath the ore-bin. Each shaft is belt-driven by a 100-hp. motor; the batteries are driven in sets of 10 stamps each.

Amalgamation of the gold is done inside the batteries, upon apron-plates, and in Pierce amalgamators. The copper plates are 4 ft. 6 in. wide and 10 ft. long, with a slope of 1½ in. per foot. After leaving the plates the pulp passes through amalgam-traps, beneath which are set the Pierce amalgamators. These machines catch about 3½% of the total amalgam. The percentages of recovery by amalgamation are:

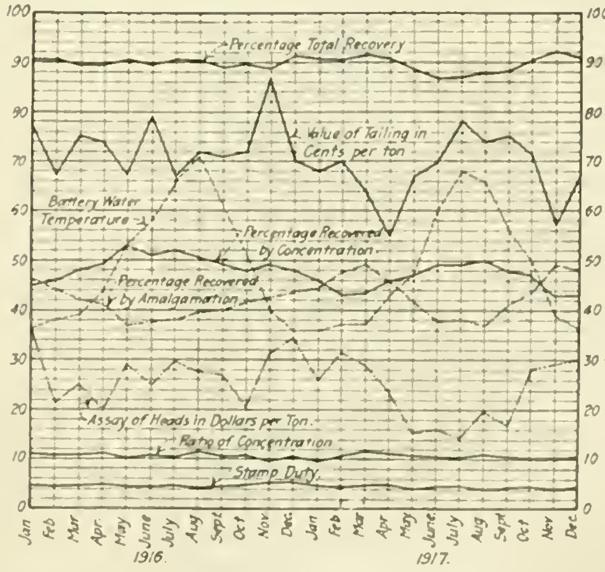
Place	%
Inside of batteries	4.50
Apron plates	92.00
Pierce amalgamators	3.50

After passing the amalgamating plant the pulp flows to two sets of vanners. These machines are adjusted to make a concentrate containing a large portion of coarse sand to facilitate leaching at the cyanide works. The concentrate goes to the central cyanide plant at Taracol. The tailing is passed to cone classifiers. The coarse spigot material flows to waste, while the overflow passes over a double set of canvas-tables. These tables collect at little cost an additional small quantity of valuable sulphide slime which is treated by agitation.

These two 80-stamp mills are similar in design and



FLOW-SHEET OF TABOWIE MILL



GRAPH OF OPERATING RESULTS AT TABOWIE MILL DURING TWO YEARS operation, and both treat about the same monthly tonnage. In the Maibong mill, the crusher is housed in a separate building, and the concentrate is treated in a small auxiliary tube-mill plant.

The company has done much experimenting at the Tabowie and Taracol plants with a view to improve, if possible, the simple yet effective milling methods in vogue. but the increased extraction obtainable has never justified the change, due to the exceedingly high cost of operating the additional machinery.

TREATMENT OF CONCENTRATE. The central leaching-plant is at Taracol, and treats all the coarse concentrates and slimes from the Tabowie and Taracol mills. The capacity of the plant is 70 tons per day, with a 20-day treatment. The plant, originally designed by S. J. Speak, contains twenty 5 by 20-ft. leaching-vats, five steel zinc-boxes, solution and stock-tanks, pumps, and accessory apparatus.

The concentrate, after being weighed and sampled for assay and moisture, is dumped into the vat. The amount of lime needed for neutralization is also added during filling, thus being well mixed with the charge. After the vat is filled the charge is given a preliminary water-wash, which is run to waste. From this stage the treatment begins, one strength of solution being used during the entire treatment.

Grading Analysis of Tabowie and Taracol Concentrates

Screen (mesh)	Tabowie Weight, %	Tabowie Value, %	Taracol Weight, %	Taracol Value, %
Through 20 on 30	18	3	3	1
" 30 " 40	20	10	20	10
" 40 " 60	17	17	26	27
" 60 " 100	11	16	15	19
" 100 " 150	7	13	8	10
" 150 " 200	6	9	7	8
" 200 (slime)	21	32	21	25
Total	100	100	100	100

After five days of percolation and aeration in the first vat, the charge is removed to another, where it receives similar treatment, and so on until it has passed through four vats and consumed 20 days of time. The final solution is displaced by water, and the residue discharged onto the tailing stock-pile.

The pregnant solution passes through a small settling-tank to the precipitation-boxes. Zinc-shaving is used in steel boxes. These are 2 ft. high by 3 ft. wide by 18 ft. long. and have six compartments, the last having a canvas filter through which the solution ascends and passes to the stock-tank. The precipitate is collected and melted twice a month.

Formerly the precipitate was melted by charcoal in well furnaces, using the following flux:

Product	Parts
Precipitate	100
Sodium carbonate	10
Borax	40
Sand	20
Manganese di-oxide	10

The gold buttons were re-melted in the same crucibles and furnace. The bars averaged 1000 oz. each.

The high cost and scarcity of charcoal necessitated a change to the use of oil as fuel. At present one large well furnace holding six No. 80 crucibles. placed in two rows of three each, with the blast-flame passing through the centre, is being used. Cupellation is done in a separate furnace designed for the use of charcoal as fuel. The cupel 'test' is made of dry cement, pressed firmly by hand into an iron casing. This change of method of melting has not yet been completed, but experiments have proved that it will be much cheaper and more efficient than the old way of melting with charcoal.

Operating Table, Taracol and Tabowie Cyanide Plant, 1918

	Taracol mill	Tabowie mill
Ore treated, tons	13,907	13,555
Assay-value	$334,372	$387,779
Value, per ton	$24.04	$28.61
Bullion recovered	$277,068	$323,081
Recovery, per ton	$19.97	$23.84
Extraction, per cent	83.0	83.3
Cost, per ton	$1.95	$1.95

The slag is re-melted later, with sweepings from the refinery, in a small blast-furnace of local make. By this means most of the metallics, which adhere to the slag while pouring the meltings, is recovered.

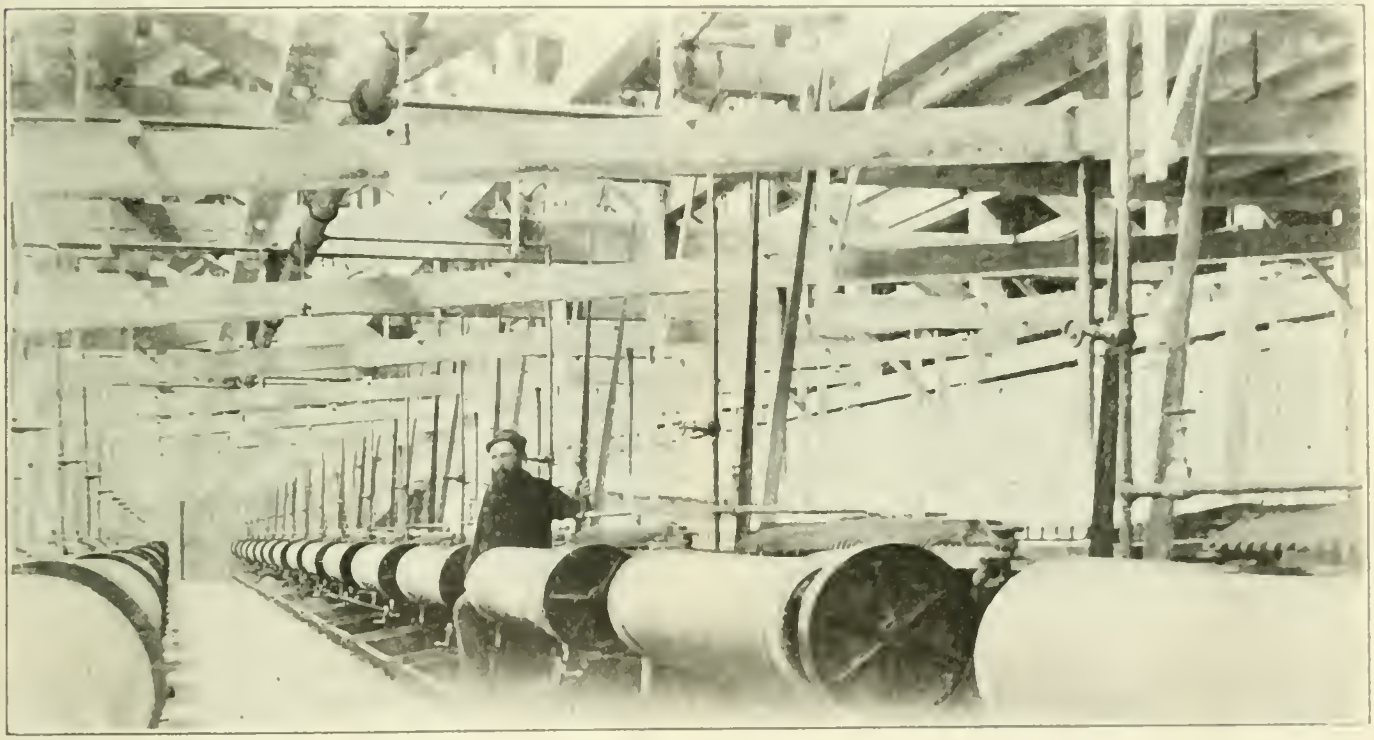
The fineness of the bullion, as sent to the Imperial Japanese Mint at Osaka, Japan, is 950 or higher. The bars average 170 oz. in weight, and are shipped by parcel post direct from the mines.

The principal feature about this leaching-plant is the simplicity of treatment with a fairly satisfactory recovery at low cost. Due to the high cost of supplies during the War, operating expenses have increased from $1.40 per ton in 1912 to $1.95 in 1918.

Cyanide Treatment Costs at Taracol Plant, 1918

Item	Quantity lb	Cost per ton
Cyanide	85,136	$0.2207
Zinc	28,440	0.0758
Lime	213,800	0.0144
Charcoal		0.0108
Cordwood		0.0436
Crucibles		0.0163
Borax	10,611	0.0583
Assaying		0.0167
Electric power		0.0848
Other supplies		0.1107
Miscellaneous		0.0117
Transportation		0.0563
Salaries and payroll		0.2061
Total		$1.0532

The use of different strengths of solution is unnecessary, as well as sulphuric-acid treatment of the precipitate. The use of sodium carbonate and litharge in the melting-flux has been discontinued, results being as good without them. The cyanide strength is kept at 3½ lb., and the protective alkalinity at 5½ lb. per ton of ore treated. The extraction has been gradually increased from year to year, and now averages over 84%.



VANNER-FLOOR, TARACOL 80-STAMP MILL

POWER. Previous to 1913 steam was used as power at all of the mines, and for part of each year in the mills and shops. All machinery except the larger hoists, which are driven by air or steam, was electrified during that year. About 650 hp., used chiefly for pumping and hoisting at the smaller mines, is procured from a hydroelectric plant belonging to the company. This plant constructed in 1906, consists of a 500-kw. turbine-driven generator, water for which is stored in a small reservoir 3 miles from the plant, and delivered through a box-flume with a head of 113 ft. Since 1913 the company has purchased 1200 hp. from a Japanese firm operating a steam-driven plant on the Anshu river, 60 miles from the mines. Electricity is used to compress air for hoisting and for rock-drills, pumping, ventilating, lighting, and for driving the mills, shops, and miscellaneous machinery.

As a rule, the mine water is lifted by stages of a few hundred feet, using centrifugal pumps on the upper levels and motor-driven vertical triplex pumps at the bottom, where the heights of stages are often changed.

The motors used are of different types and sizes as deemed most suitable. Auxiliary generating units, connected with the old steam plants, are maintained in case of any interruption to the regular supply.

The company has just commenced construction of another hydro-electric project on the Kuron river, 25 miles from the mines. The work will consist of a 650-ft diversion dam, a 955-ft. tunnel, power-station, and transmission-line to the mines. The water will be delivered to the generators under a 45-ft. head, producing an average of 1000 kw. This new source of supply will materially reduce power expenses.

MECHANICAL. This department, always indispensable around mining plants, is doubly so on these mines because of their isolation from sources of supplies. The work that this department is called upon to do ranges from the making of nuts and bolts to the manufacture of complete machines. Considering the range and quantity of the work demanded of it, the equipment is simple, consisting of one 30 in. by 22-ft. lathe, one 24 in. by 9-ft. lathe, one 16 in. by 5-ft. lathe, one 3½ by 3½ by 8-ft. planer, one 22-in. shaper, one 4-ft. radial-drill, one upright drill, and pipe-threading machines.

The wood-working shop is equipped with the usual complement of lumber and timber-planers, rip and band-saws, turns out all manner of wood material, does the framing for all new construction, dresses the lumber for other departments, and furnishes patterns for the foundry.

The blacksmith-shop has all the machines and tools usually found in a good shop.

The small foundry operated by the department has a normal capacity, when using coke, of two tons per hour. However, coke being unattainable at present, charcoal is used and the capacity of the cupolas is considerably decreased. The foundry casts all liners, guides, and feeder-tables for the mills, in addition to the innumerable small jobs that turn up daily from the mines and metallurgical plants.

In the company shops are built the smaller hoists used at the various mines, also many of the electrically-operated pumps, of the vertical-triplex type, as well as much other machinery needed.

All machinery in the shops is electrically driven, power being supplied by the company's hydro-electric plant. Most of the machinists, blacksmiths, foundrymen, carpenters, and pattern-makers are Japanese; however, Koreans have been trained throughout the department and do satisfactory work. The wages in this department are higher than in any other, and materials are so hard to procure that a comparison of costs would not, at present, be fair to the plant; however, it serves its purpose well, and too much credit cannot be given it.

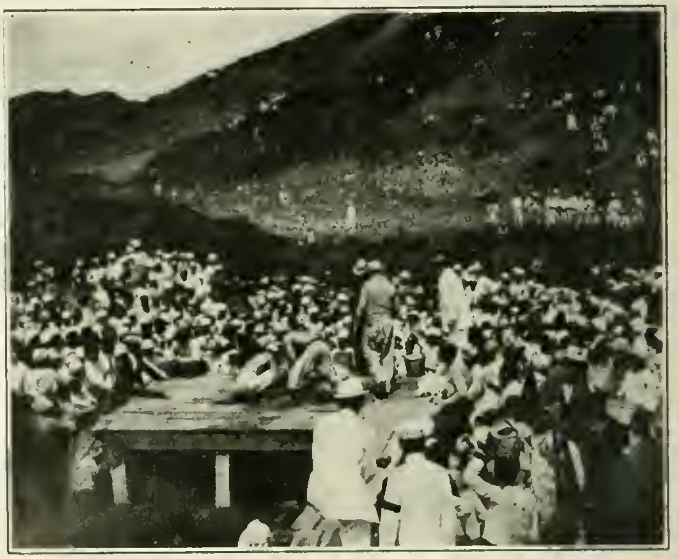
Timber Supply. The comparative scarcity of timber, coupled with the high cost, makes it an important item in the local cost of mining. Below is given a table showing the cost of timber, cordwood, lumber, and charcoal used at all mines, showing the timber to be 25% of the total mining cost for the fiscal year 1918. Ore mined, 303,672 tons.

Material	Cost
Cordwood	$0.06972
Mining timber	0.30921
Lumber	0.05654
Charcoal	0.01047
Total timber cost	0.44594
Total mining cost	1.82979

The company's timber concession lies to the north of Unsan in the two adjoining districts, the boundary being a chain of rugged mountains rising 2000 ft. above the floor of the valley, wherein are situated the two largest mines—Tabowie and Taracol. These mountains, forming an effective barrier to all ordinary means of transportation, necessitated the construction and operation of a small railway and gravity planes. This is now an organization, separate from the mines, and its operation has proved satisfactory and economical. During the first 10 years of operation the company purchased all timber from native contractors cutting in Government forests, but the exclusive timber-right on the present concession, a mountainous region 300 square miles in area, was obtained from the Japanese Residency General during 1909. The bulk of the forest consists of oak, maple, birch, and ash; the maximum size averages 2 ft. diameter. In addition there are some fir, scrub pine, and other soft-wood trees. All cutting is done by contract, supervised by company rangers, who enforce compliance with the Government forest regulations regarding protection of young growth, and the leaving of certain varieties of trees.

The narrow-gauge railroad, started in 1906 at a pass two miles from Tabowie and at an elevation 1500 ft. above the mine, winds around the mountain sides into the timber-belt. The road has been extended yearly to a total length of 20 miles, and is used exclusively for transporting timber and lumber. Being built around the sides of the rugged mountains, it of necessity has many sharp curves and some steep grades. Many of the curves on the older sections of the road have only a 50-ft. radius. The railway is also a scenic wonder, and many visitors are unanimous in proclaiming it the "crookedest road existing." A yearly tax of $12,500 for re-forestation of this area is paid to the Government.

Labor. One of the original, and which later proved to be one of the most important agreements between the Emporer and the concessionaire, was a condition that natives should be employed to as great an extent as possible in all branches of the company's business, and all due facilities given them to acquire a knowledge of modern mining methods as carried on abroad. This agreement seemed to be an anticipation to Mr. Perkins' policy of always using local labor. By the support of the manager and the sympathy of his staff at the mines the company has fulfilled this labor pledge so far as was found practicable.



NATIVE DRILLING-CONTEST ON JULY FOURTH

The labor question here, however, has never offered any serious perplexities. About 90% of the men are Korean. The number of Chinese workers is on the increase; their work underground is confined to drilling in hard ground and as trammers, and on the surface as stone-masons and general rough workers. The more skilled laborers, such as carpenters, smiths, and machinists are mostly Japanese.

The Koreans' environment seems to lend them a special aptitude for underground work, and after a comparatively short training make excellent miners. They are fairly intelligent, docile, obedient, and easy to handle.

but careless and require strict supervision. They work intermittantly, due principally to a failing for alcoholic beverages, but remain at work on the mines for years, and not a few have been employed since the beginning of operations. The average native will perform about one-third the work of a white man under the same conditions. Their wages range between 25 and 40 cents per day.

The Chinese are more industrious and enterprising than the natives and physically much stronger, but as a general all-around mine workman the Korean has proved himself far superior and more efficient than his celestial rival. Aside from the few Chinese mentioned above, the Korean performs all the labor in the mines, on the surface and about the mills and cyanide works; as blacksmiths, machinists, carpenters, in the metallurgical plants, and even in the accounting and engineering departments they have shown their ability. In many departments they have replaced high-priced white employees to a large extent. Between 4000 and 5000 Koreans find employment with the company.

SAFETY AND WELFARE WORK. Until a few years ago, the real value of safety work was not recognized; rather dangerous practices and conditions existed in the mines and the accident rate was high. By co-operative efforts the mine officials have brought about a marked change for the better. Excellent progress has been made in this work during the past three years, and today the accident rate among the native miners is little over that in many American metal mines.

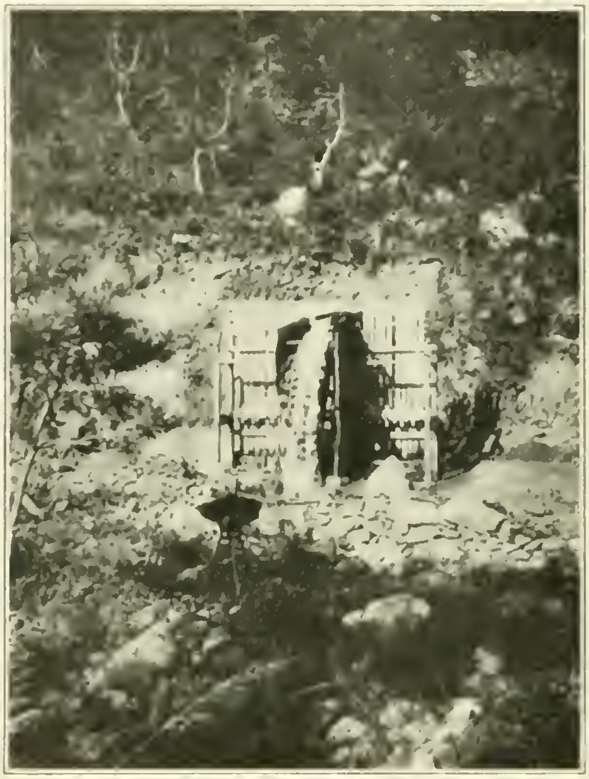
A manifestation for the welfare and safety of their fellow-workmen is now shown by the natives, a characteristic entirely lacking a few years ago. Now all dangerous and unprotected working places are reported immediately to the shift-bosses, and accidents and fatalities are reported to the Police Department, which makes a thorough investigation of each case.

The increasing depth of the workings, great quantities of decaying timber, and high temperatures, coupled with the natives' natural carelessness, makes the danger from mine fires a constant worry to the management. The company keeps at each of the large mines a boss trained in first-aid work and the use of rescue apparatus.

The company donates considerable sums of money to the civil authorities for the promotion of welfare work among the miners. Among these things might be mentioned street improvements, establishment of a fire department, a large central free bath-house, support of a sanitation service, and donations to schools and numerous civic organizations and activities. Besides this the company also maintains a large and well-equipped hospital run under the direction of a competent physician and surgeon. All medical treatment is free to the company employees and their families.

Having large and proved resources the company has made all improvements of a permanent and substantial character. The foreign operating staff, numbering about forty-five, and their families, are well housed with all modern conveniences, everything being furnished by the company. A fine civic centre has also been established with a school-house, recreation grounds, tennis-courts, etc., and a large club-house for social gatherings and amusements. The company's welfare work is being promoted in a commendable manner and it has proved a good investment. The company's concession rights date to 1951.

GENERAL. Being so distant from the base of all supplies, the company has always made a practice of keeping on hand a large stock of mining materials and spare parts for machinery. The value of such a policy was demonstrated at the outbreak of war, when shipping facilities were so badly disorganized. The transportation department handles all supplies and freight from the various ports of entry. This department formerly conveyed all the bullion from and money to the mines, but these have been transported through the Imperial Japanese post-office since the attempted robbery by bandits in October 1916. The expense of transportation represents a considerable item on the supply cost-sheet.



NATIVE MILL USED BY PROSPECTORS

Besides the mines now operating the company has a number of partly developed prospects, which later will be brought to the producing stage. The exploration department is continually seeking new prospects, and it is not improbable that more deposits may yet be found within the company's concession. Extensive alluvial deposits, the richer portions of which were worked early by the natives, extend through the area and cheap power may make them yield a profit by the use of dredges.

A large concentrate tailing dump at Taracol, the accumulation of years of leaching at the central cyanide plant, is expected to yield a good profit by re-treatment after fine grinding, as soon as a lower cost of chemicals and supplies will warrant construction of suitable plants.

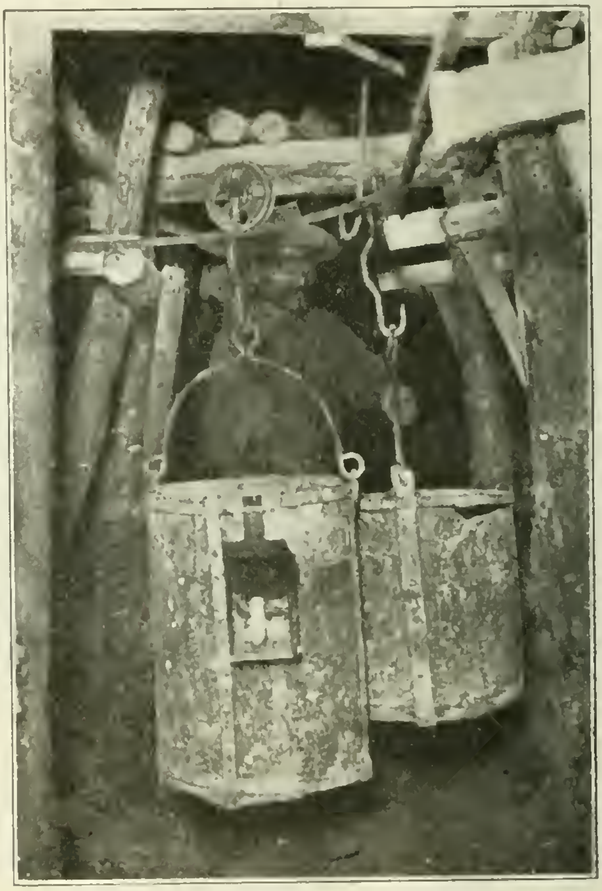
The Oriental Consolidated Mining Co. has, since beginning operations in 1896, mined 4,766,270 tons of ore having a gross value of $29,423,235, from which $7,938,645 has been distributed among shareholders as dividends.

The writers acknowledge with thanks the suggestions and data given by the various department heads and plant foreman, as well as the interest and aid extended by the management. The company officers are: Henry C. Perkins, president; Alf Welhaven, general manager; Thomas W. Van Ess, assistant-general manager; and Joseph B. Lower, superintendent.

Mining in the Footsteps of Javan

It was D. C. Jackling who said that all the great porphyry copper mines of today had long been known as sources of that metal, although upon a far smaller scale. This is a broad generalization, but not so universally true as to act as a deterrent upon investigation of copper prospects that lack an industrial history. Nevertheless the feeling is strong among copper miners that the old sources of world supply are worthy of re-examination. Several years ago an expedition was sent through the Sinai peninsula where the Egyptians mined and smelted copper actively in the epoch of the Rameses. It is here that Moses is supposed to have gone before his exile, and to have had some connection, as a royal representative, with the cherished copper industry. Another group of American engineers was sent into the northern part of Asia Minor to study the deposits that were worked by Tubal Cain, the traditional and semi-historic father of iron and copper metallurgy, leading to an industry that was great for that age, and which made his descendants, the Tibareni, noted throughout the world. They were the early makers of brass instruments of music, which were shipped to all countries, and the steel which they produced served as the basis for the skilled workmen who turned out the famous Damascus blades. Except for the catastrophe of war these ancient mines by this time would have become active again, producing copper under the direction of American mining engineers and metallurgists.

Another early centre of copper production was the Island of Cyprus. The very name of this bit of land means 'copper', Κυπρος in the Greek, from which came the Latin name for copper, cuprum. In the Scriptures the island is known by an early form of the same word, that is, Kaphtor, and it is told that Javan, a brother of Tubal Cain, both being sons of Japhet, went there, and he is said to have become famous as a worker of copper on Mount Alasya, on the Cyprian island. The mines were long regarded as an important source of copper, and were worked by the Phoenicians and later by the Romans. The accompanying picture of a Mediterranean miner with an ore-bucket on a trolley was taken by Karl S. Twitchell, formerly engineer for the De Lamar mine in Idaho, in present-day exploratory workings on these same deposits that are supposed to have been operated in a primitive way by Javan and the tribe that sprung from him. This mono-rail haulage system is in use on the 915-ft. level of the Skouriotissa mine in Cyprus. Mr. Twitchell writes, "We cannot get any track, cars, or other mine supplies, so I rigged up this scheme, and it works very well. The rail is mostly $\frac{7}{8}$-in. octagonal drill-steel. The buckets are carbide drums. These buckets are run to the shafts, unhooked, and put on the hoist-rope." Mr. Twitchell has found that the peculiar knack of the pioneer in new fields has its value also in realizing the opportunities present in regions dominated by the remnants of worn-out civilizations. He was engaged in cutting timbers and in making lumber by primitive methods for the use of the British army in Egypt before going to Cyprus.



A MAKE-SHIFT

MILLS AND CYANIDE WORKS in the goldfields of Ontario have a total daily capacity of 6110 tons, says the 'Mining Review' of Cobalt. There are 20 plants, of which 16 were closed during the latter part of the War; but many are to resume soon. Porcupine mills can treat 5400 tons per day, the Hollinger leading with 2800, and Dome with 1350 tons. Kirkland Lake mills treat 490 tons; while the two at Boston Creek treat 80, two at Munro 90, and two at Larder Lake 50 tons.

The Colorado Pitchblende Company

[*]The following report was addressed, on February 18, 1919, to the President of the Colorado Manufacturers Association. It is signed by Richard A. Parker, as chairman, and George A. Stahl, as secretary:

The Mining Bureau of the Civic and Commercial Association which, at your solicitation in December last, named Mr. J. M. McClave as an engineer to be employed by the Colorado Pitchblende Co. to examine and report upon its property, received the final draft of Mr. McClave's report on February 13, 1919. We hand you herewith the McClave report, together with his bill for services. Please see that the bill for Mr. McClave's services is paid before delivering the report to the Colorado Pitchblende Company.

The following comment upon the company and its enterprise seems appropriate and proper.

The subject in hand naturally divides itself into three principal heads:

1. The company's promotion methods.
2. The engineer's report.
3. The commercial aspects.

1. The company's promotion methods. We feel that the advertising methods adopted by the company cannot be too strongly condemned. The advertisements which have appeared are hugely sensational and manifestly designed to induce small investments in the hope of securing large profits which we believe can never be realized. The company's advertisements contain certain misleading statements, for instance,

(a) "$3,290,400 a year potential profits," when such profits can be realized only if and when a 1000-ton mill is constructed and operated on the basis of anticipated success and assumed market conditions, neither of which we consider warranted from figures submitted.

(b) "It is estimated that less than $1,000,000 will be required to equip this company with production capacity equaling one thousand tons a day (or $3,290,400 profits a year). This would indicate that each dollar invested would earn $3.29 a year."

This statement leaves out of the calculation the 640,000 shares of outstanding stock which, of course, must participate equally in profits with the stock which the company is proposing to sell. On the basis of the company's own figures, each share of 1,140,000 shares of stock outstanding in a company earning $3,290,400 per annum would be entitled to $2.80, or, as the company is now offering stock for $2 per share, the profit on the price paid would be 140% per annum instead of 329%, as stated in the advertisements.

These advertisements are calculated to arouse an abnormal sympathy and interest in the general public by strongly intimating, in fact, charging in some instances, that those who do not believe in the wonderful future claimed for the enterprise and, therefore, conscientiously urge conservatism in respect to it, are actuated by unpatriotic motives, when nothing could be further from the fact.

The advertisements emphasize the property as a radium property, thus exciting the popular conception that the enormous profits claimed are to come from the recovery and sale of that rare and mysterious mineral, when the reports show, as a matter of fact, that other products are expected to return more than one-half of the anticipated profits when operating on a 1000-ton basis.

We feel that the Colorado Pitchblende Co. is not justified in either the method or substance of its advertisements.

The Denver Civic and Commercial Association is, of course, always anxious to aid any meritorious Colorado enterprise which is conservatively managed and on a sound business footing, but the Mining Bureau feels that the advertisements of the Colorado Pitchblende Co. are of such a nature that it cannot be regarded as in the class entitled to any manner of commendation at the present time.

2. The engineers' report. The report of Mr. James M. McClave, who was designated by this Bureau to examine the Jamestown properties, at the expense of the Colorado Pitchblende Co., is attached hereto.

We cannot agree with the conclusion reached by Mr. McClave from the figures contained in his report. We accept Mr. McClave's conclusion that there is a large tonnage of ore in the properties examined, but we do not believe that there has been a sufficient measurement of technical ore to justify any determination of total available tonnage, and, upon the experience of many competent authorities, we believe his estimates of mining costs are low.

We also accept his conclusion of a probable 75% recovery in a suitable mill, notwithstanding the fact that the conclusion is based entirely on laboratory experiments and is not supported by mill-tests; we think, however, that there must be an additional loss of 10% in that portion of the mill-product which must be subjected to oil-flotation, and a further loss of 20% in the chemical treatment of the uraninite for the recovery of the radium.

3. Commercial aspects. From a commercial standpoint there are three products to be considered:

(a) The gold-silver-lead concentrate.
(b) The fluorite.
(c) The uraninite.

(a) The gold-silver-lead concentrate. Upon the evidence of experienced producers of all classes of minerals we feel that Mr. McClave's estimate for freight and treatment charges is low. However, assuming his figures of $2.70 as the per ton value of gold, silver, and lead in the crude ore, and $3.50 as the per ton cost of operation, it is manifest that this product alone cannot make a profit.

---

[*] Report of the Mining Bureau of the Civic and Commercial Association, of Denver.

(b) The fluorite. Our inquiry into the fluorite situation convinces us that no considerable market can be anticipated for this product in the future. Immense accumulated supplies in excess of the market requirements, produced as an incident in metal mining, have for years been available in England for immediate shipment. That this competition has been formidable is evidenced by the large tonnage imported in the past notwithstanding a duty of $1.50 per ton. This competition will undoubtedly return as ocean transportation returns to normal conditions. The domestic production has come mainly from the Illinois-Kentucky district where the pre-war prices obtained were fixed largely by the cost of production. That this district failed to furnish sufficient for our entire home consumption in the immediate past, appears to have been due to the labor shortage and not to any deficiency in the source of supply.

Fluorite was not shipped from Colorado until the abnormal conditions in the iron and steel industry, due to the War, had caused prices to advance sufficiently to overcome the heavy freight to Eastern points of consumption. Under these conditions several thousand tons of Colorado fluorite were sold, but it appears extremely doubtful if such sale could continue should the price recede to a level even considerably above that prevailing before the War.

Extensive inquiry among producers and consumers failed to develop any active demand at present, the only spar moving to market now, being such as is shipped under long-time war contracts. The proposed production of the Colorado Pitchblende Co. equals fully half the entire United States consumption in 1917 or 1918, and such an amount, if placed upon the market, would create a great over-supply. Under such conditions the Illinois-Kentucky field would probably be the one to survive, owing to low production cost and proximity to market. The higher price which the washed product is claimed to command would scarcely half offset the higher freight-rate to points of consumption.

(c) The uraninite. This subject divides itself naturally into two parts: (1) uranium oxide, and (2) radium.

1. Uranium oxide. At times small quantities of this commodity are marketed but consumption is so small that it cannot be regarded as a source of income.

2. Radium. After investigation of the possibilities of profit from the radium in the uraninite content of the ore, we submit the following figures as our estimate of the maximum profit available from an ore containing 1.08 pounds of pitchblende per ton, such as the ore under consideration:

Basis:	
Uraninite content of ore, per ton	1.08
Value of radium, per mg	$100
Cost of chemical treatment, refining, and marketing, per mg	$ 10
Loss by table concentration, per cent	25
Loss by oil-flotation, per cent	10
Loss by chemical treatment and refining, per cent	20

Calculation:	
Value of radium in 1.08 lb. uraninite	$ 13.82
Loss by table concentration, 25%	3.45
Value of radium in water concentrate	10.37
Loss by oil-flotation, 10%	1.03
Value of oil-flotation product	9.34
Loss by chemical treatment and refining, 20%	1.87
Value of final radium salt	7.47
Cost of chemical treatment and refining	5.00
Value of final product per ton of ore	2.47

These figures, however, are based upon the assumption that the entire overhead mining, operating, and milling costs of recovering the uraninite from the crude ore have been borne by other products. If such costs are to be charged to the radium product alone, the profit would disappear.

Conclusion: Our conclusion is that the business hazards of this enterprise, which we have touched upon briefly in this report, are such that its commercial success is a problem still insufficiently demonstrated, and that, upon present evidence, no such profits as advertised can be expected.

Mineral Production of Ontario

Preliminary figures for 1918, prepared by the Bureau of Mines at Toronto, have just been issued. The principal products are as under, compared with 1917:

	1918		1917	
Product	Quantity	Value	Quantity	Value
Cobalt, metal, pounds	404,348	$887,960	396,395	$589,290
Cobalt, oxide, pounds	476,053	725,105	418,703	533,489
Copper, tons	23,556	8,532,700	21,466	7,961,662
Fluorspar, tons	1,834	42,102	4,327	66,974
Gold, ounces	411,879	8,502,542	420,893	8,698,735
Gypsum, tons	38,214	151,564	48,493	130,138
Iron, pigs, tons	50,072	1,359,541	49,485	1,016,699
Iron pyrite, tons	267,786	1,152,027	286,049	1,111,264
Lead, tons	835	149,841	886	172,601
Molybdenite, pounds	17,614	59,067	77,517	47,614
Nickel, tons	44,297	26,578,200	41,887	20,943,500
Silver, ounces	17,409,264	17,364,918	19,479,692	16,183,208
Talc, tons	17,465	246,691	16,076	179,554

The total value of metallic products was $66,119,792, and non-metallic $14,045,928, against $56,831,857 and $15,261,975, respectively, in 1917.

The outlook for gold mining for 1919 is considered bright. Last year, Porcupine produced 816,037 tons of $9.60 ore, and Kirkland Lake 55,523 tons of $11.89 ore. The Hollinger led with 578,755 tons valued at $5,706,214, followed by the McIntyre with 176,976 tons and $1,561,735, Lake Shore with 16,749 tons and $415,230, Tough-Oakes with 22,000 tons and $136,828, Porcupine Crown with 10,907 tons and $123,563, and Dome Lake with 11,929 tons and $100,799. The Hollinger, McIntyre and Lake Shore distributed $1,873,042 in dividends.

The silver output was 17,409,263 oz., of which 16,558,420 oz. came from Cobalt and 774,403 oz. from Gowganda and other districts, a total of 17,332,804 oz. Of this, 9,506,017 were extracted at Cobalt, 5,014,469 oz. at refineries at Deloro, Thorold, and Welland, and 2,812,318 oz. at refineries in the United States.

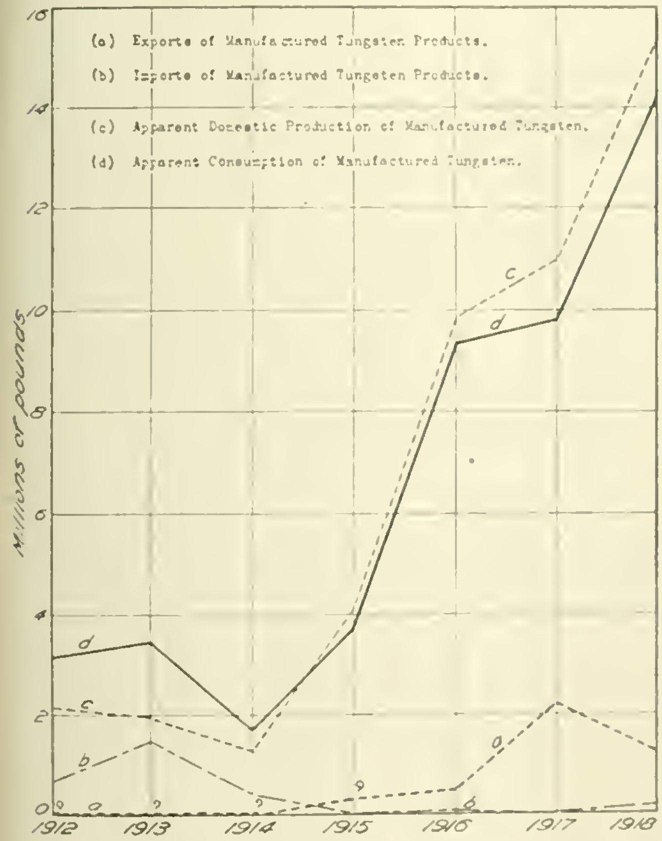
Mines yielding over 1,000,000 oz. were: Coniagas, 1,006,104 oz.; Kerr Lake, 2,221,811 oz.; Mining Corporation, 1,994,061 oz.; Nipissing, 5,785,739 oz.; and O'Brien, 1,074,312 oz. Seven companies distributed $4,696,513 to shareholders, making $75,518,342 to date.

Tungsten

Of the $8,500,000 available for re-payment under the War Minerals Relief measure, it is estimated that tungsten producers will receive a large proportion.

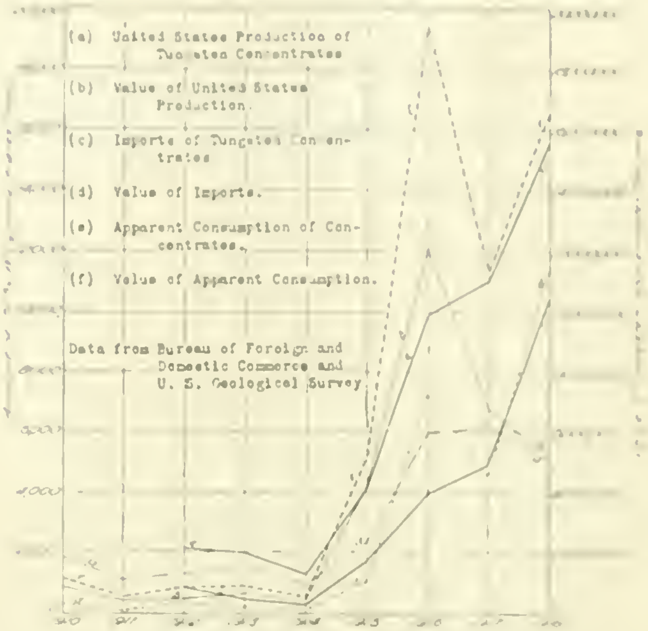
The following notes, including the graphs, are from the February report of H. C. Morris of the U. S. Bureau of Mines:

The information obtained from various sources regarding tungsten and tungsten products during the month indicates clearly the extremely unsettled conditions of the industry in every branch. Estimates as to stocks of concentrates on hand in the East varied from 2500 to 7000 tons, and showed the desirability of some such assistance as the trade will receive from the compilation of reports or questionnaires. A moderate amount of concentrates of good grade have been disposed of during the past month at considerably under $10 per unit, and it is reported that England is offering first-grade material for 30 shillings ($7.20). It is also said that a standard grade of English high-speed steel is being offered in New York at $1.70 per pound, and that some such steel may come on the market at a much lower price. The curves presented herewith show various interesting and pertinent facts regarding tungsten and tungsten products.

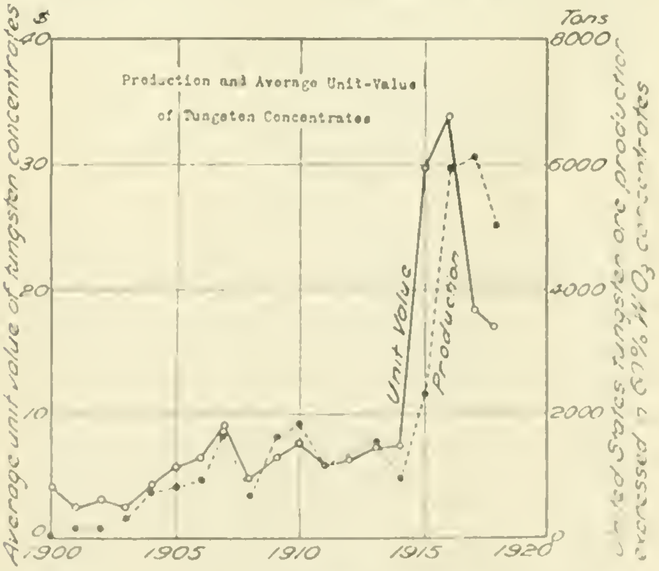


At a meeting of the Tungsten Committee held at New York on March 12, the following resolution was proposed and adopted, according to advice from Charles Hardy:

"It was moved that the chairman appoint a committee of three to present to James T. McCleary, secretary of the American Iron and Steel Institute, a resolution known as 'Resolution No. 1' in person, and to explain to Mr. McCleary the personnel of the committee of nine, the method of election and our right to represent the industry, and that we also ask of the American Iron and Steel Institute that our committee of nine, known as the Tungsten Committee, receive consideration in the appointment of a chairman to represent the tungsten industry in presenting our case to the Redfield Peck Commission through their assistance."



Discussing the position of the tungsten industry of Sheffield, England, John M. Savage, U. S. Consul, said that the demand for high-speed steel has dropped to such an extent that one of the new tungsten plants at Sheffield alone is able to supply more of the alloy than is needed in that city, and grave apprehensions are felt as to future requirements. Meanwhile the Government has reduced the price of wolfram ore £1 10s. ($7.20) per unit, and the prices of ferro-tungsten and tungsten powder have fallen 2s. (48 cents) per pound.



Rapid Method for Determination of Tungstic Oxide

By F. A. RAPP

The following, a modification of Low's cinchonine sulphate analysis, is a quick method for tungstic acid in scheelite. By slightly changing the procedure, concentrate may also be tested. This system was used by the Tungsten Mines Co. at Bishop, California.

Grind 2 grammes of the sample to a fine powder. Weigh into a 600-cc. beaker. Digest slowly on the hot-plate with 40 cc. of aqua regia (10 cc. nitric and 30 cc. hydrochloric acid). Take down to 5 to 8 cc., stirring occasionally. Remove, add about 100 cc. of water and stir. After settling for half an hour, filter through an 11-cm. filter paper, retaining as much of the residue as possible, in the beaker. Add to the beaker about 5 cc. of the ammonia solution made from 80 cc. ammonium hydroxide, 4 cc. hydrochloric acid, and 400 cc. of water. Warm on the hot-plate and pour through the original filter. Repeat this operation. Wash beaker and filter three times with a 2% hot ammonia solution.

Remove filtrate from underneath the funnel, and add about 6 cc. of the cinchonine solution made from 50 gm. cinchonine sulphate, 200 cc. hydrochloric acid, and 200 cc. of water. In case the filtrate is not acid before adding the cinchonine solution, it should be made so by the addition of a little hydrochloric acid. Place the beaker on the hot-plate and heat for 1 hour, or until all the WO_3 is precipitated. Remove and filter, catching the precipitate on a 9-cm. ashless filter-paper. Wash 7 to 10 times with a dilute solution of the above cinchonine solution. Ignite the filter in platinum and weigh, subtracting the weight of the filter-ash. The difference in the weight will be WO_3. Divide by 200 to get the percentage.

Calcium Carbide Derivatives

By F. H. MASON

The exigencies of war have done much to awaken the genius of chemists all over the world. In the 'Press' of January 11, I gave an outline of the methods of preparing acetone from seaweed at the Hercules Powder Co.'s plant, near San Diego. As stated then, acetone came into great demand during the War for the blending of nitroglycerine and nitro-cellulose in the manufacture of cordite and other high explosives. At Shawinigan Falls, in the Province of Quebec, acetone was prepared on an extensive scale by quite a different method. There, acetylene, prepared from calcium carbide, is first subjected to treatment with sulphuric acid and a salt of mercury, which convert it into acetaldehyde. After purification by distillation, this compound is converted into acetic acid by a catalyst, and the acetic acid, after purification by distillation, is oxidized by the aid of a catalyst to acetone. Fortunately, there is no need for an obituary notice, as was the case with the San Diego plant, to the two plants at Shawinigan Falls, for, though there is no longer any great demand for acetone, such a high grade of acetic acid is produced that it is in considerable demand for the manufacture of dyes and for other industrial purposes. After distillation, the acid is over 99% pure, and is entirely free from tars and resins, so often associated with the acid when it is obtained from the destructive distillation of wood, and so detrimental in the manufacture of fine dyes. The two plants at Shawinigan Falls have been in operation since 1916, and each yielding from 700 to 800 tons of glacial acetic acid per month.

As long ago as 1907, calcium carbide was used for the manufacture of calcium cyanamide, from which ammonia has since been prepared, while the ammonia thus made has been oxidized by the aid of a catalyst to nitric acid. In fact, everything seems to point to the bulk of the nitrates of the future being made from the air by the aid of calcium carbide. Recently, carbide has come to the front as the starting point for the synthetic preparation of a number of chemicals, among which may be mentioned alcohol, acetylene, tetrachloride, chloral hydrate, chloroform, ethyle acetate, formaldehyde, and monochlor acetic acid. This seems likely to be only the beginning of a long list of chemicals that in future will be derived indirectly from calcium carbide. Thus, it will be seen, largely through the use of catalysts, calcium carbide, which originally was discovered accidentally during the attempt to reduce the metal calcium from lime by carbon in an electric furnace, seems likely to become a competitor with coal-tar as the nucleus for the synthetic preparation of many chemicals hitherto made by more costly methods.

Shaft-Sinking Record

By R. C. WARRINER

A new world's record in shaft-sinking was made during December 1918, at the Crown Mines, Johannesburg, of which I was consulting engineer to the end of 1918. The shaft in question is circular, having an outside diameter of 21½ ft., and 20 ft. inside the walling. During the period mentioned it was sunk 279 ft. from a depth of 655 to 934 ft., equal to an average of 9 ft. per 24 hours. The previous world's record was also held by this company, when 252 ft. were sunk in a 31-day month at No. 14 circular shaft of the Crown Mines. This was also a 20-ft. shaft. The cost of sinking, exclusive of walling, was between £13 and £14 ($62.40 and $67.20) per foot.

Sulphur remains at the same price as during the War, namely, $22 per ton, f.o.b. mines. Little business is being done at that figure, but the Louisiana-Texas producers are not inclined to make any cut.—Sulphuric-acid production has been curtailed considerably, and 66°B. acid is offered at $20 per ton in the East. By-product acid, 50°, from zinc plants, is as low as $10 per ton at Chicago.—Pyrite stocks were large last November, and until these are absorbed, and markets and prices are re-adjusted, the demand is likely to remain uncertain.—R. R. Horner in charge of this division of the U. S. Bureau of Mines.

REVIEW OF MINING

DIVIDE, NEVADA

The Tonopah Divide Opens Rich Ore at 465 Ft.; Official Assay Given.—What is Being Done by Others in the District.

A meeting of operators and claim-owners has adopted formally the name of Divide to designate the district, and the townsite will be known as Divide. Application will be made later for a post-office; mail is now received at Tonopah.

In the Tonopah Divide mine, the silver vein has been cut on the 465-ft. level. The shaft has been sunk below 550 ft., and another cross-cut will be driven to the vein at 565 ft. A. I. D'Arcy, the consulting engineer, has supplied the following information: The fourth level cross-cut penetrated the vein 140 ft. from the shaft, in low-grade material, over 25 ft. wide. The drift south-east near the foot-wall entered ore within a short distance. This drift, the main haulageway for this level, is at least 5 ft. wide. A sample across the face, 30 ft. from the cross-cut, assayed $269.10, containing 1.26 oz. gold and 243.9 oz. silver. The second round following exposed a full face assaying $473 per ton. On the third, 365-ft. level, the ore-shoot has been developed for a length of 420 ft., and the south-east drift is still in shipping ore. The raise from this level, 250 ft. from the shaft cross-cut, is up 40 ft. Mine-car samples for this distance give an average of $70 per ton. This raise will connect with the second level at a point where ore assaying $58 has been opened for a width of 30 ft. The sill on the third level, at the fault intersection, is now 50 by 20 ft. and broken to a height of 10 ft. Ore broken in this area has averaged over $80 per ton. One day's output of 46 mine-cars sampled $95 per ton. Shipments of 35 tons daily go to the MacNamara mill at Tonopah. The treatment cost is $5 per ton and extraction is over 90%. Freight teams are used to haul the ore. Before April 1 the volume of output will be increased, but not in large measure. The milling contract provides for a minimum of 40 tons and maximum of 60 tons daily. When water-level is reached, the directors will consider building a mill at the property. The nearest present water-supply is at Tonopah.

On the 500-ft. level of the Brougher Divide, the south cross-cut from the shaft has penetrated the Divide vein 25 ft., the vein material assaying $6 to $7 per ton. Drifts are being started both ways in the vein. Two seams of ore, assaying $18.85 and $80, were cut in driving to the vein. No other work has been done below the 177-ft. level, where small seams of ore were found.

In the Gold Zone, a drift is being advanced south-east on the vein at the 500-ft. level. This has exposed some $16 and seams of high-grade ore. Similar ore was found at this depth near the Divide boundary, at the north-west. Cross-cuts are to be driven here to explore for parallel veins.

The Hasbrouck company's 900-ft. tunnel has cut the main lode of the mountain at great depth, and has exposed good ore, showing free gold. This point is over 600 ft. below the apex. The first vein, 400 ft. from the portal, produced 1000 tons of $15 ore when silver was at 50 cents per ounce, and the consulting engineer estimates 3000 tons of similar ore available for shipment. The product will be sent to a mill at Tonopah, beginning shortly. The 400-ft. shaft is being re-timbered and equipped with high-power hoist and compressor. The first vein will be cut within 80 ft. of the shaft, 460 ft. below the tunnel-level. The company has $35,000 cash. George A. Kernick is president and H. F. Bruce is manager.

On the Gold Reef Divide property, adjoining the Gold Zone on the south-east, the main shaft is being sunk with good machinery at a point nearly in line with the trend of the Divide silver vein. The property has been prospected by several shallow shafts, open-cuts, and a short tunnel, exposing ore in small quantity, and one shaft contains the only water in the district. 'Dick' Williams has held this group for 12 years. The directors are San Francisco men, identified with the Western Union company.

The High Divide company, controlled by Wingfield and Brougher, has started work on its large group, covering a high conical mountain north-east of the Divide mine.

The Divide Consolidated has one of the best surface plants in the district, and is sinking a two-compartment shaft on ground adjoining the Brougher Divide and in line with the Divide fissure. Vein breccia broken near the surface assayed $9 across the width of the shaft. The company is leased by J. H. Miller, and Richard Finn is superintendent.

The East Divide shaft is down 370 ft. and cross-cuts will be driven at 400 ft. The shaft is in the lower Divide breccia, so-called, which forms the casing of the Divide vein, and seams of quartz have appeared. A large compressor has been provided to supply the drills of the East Divide and adjoining Alto Divide.

Equipment on the Alto Divide, adjoining the Gold Zone and Gold Reef, is complete, and sinking is in progress near the large vein exposed on the East Divide.

The Divide Extension shaft is making good progress near the Divide boundary and near a vein parallel to the Divide fissure. Zeb Kendall is president and manager.

Machinery of the Sutherland Divide will be in operation shortly at the 400-ft. incline shaft, near the Tonopah road. The property has shipped high-grade ore in the past, from the deep shaft and from shallow workings farther east. The shaft will be sunk 200 ft. deeper and drifts will explore the vein on the 300 and 400-ft. levels.

The Tonopah Dividend shaft is being sunk below the 300-ft. level, where two veins were explored without finding pay ore other than in small seams. Quartz seams, yielding low assays, have been cut in the shaft.

The Florence Divide, adjoining the Sutherland, is preparing to sink a deep shaft.

On the Rosetta Divide the new shaft has been started near a large vein from which good assays are obtained.

The Gold Wedge Divide, in the south-eastern part of the district, is sinking with good equipment near the Rosetta vein.

The Allied Divide, with claims adjoining the Gold Reef and East Divide, has secured hoisting equipment and will begin sinking its shaft soon on the Marquette claim.

The Gold Wedge Homestake group, owned since 1901 by William Watters, superintendent of the Tonopah Divide mine, has been transferred to Hugh H. Brown, counsel for the Tonopah Mining Co., as trustee for men connected with that company.

GOLD HILL, OREGON

Status of Mining in Southern Oregon.

Chrome miners in this region, who all suspended work in November, are still inactive, not taking up the mining of other minerals. They were all heavy losers and are collecting proofs of their losses in hopes of recovering from the appropriation made recently by Congress. Many, if successful in obtaining repayment, will be able to resume gold mining, in which they were engaged before the War. But little gold mining will be done in this district under the present high prices for machinery, supplies, and labor. A few fully equipped properties will be operated in the coming season, but no new development will be undertaken. The manganese properties are closed. The Rainier Mercury Co. and several small properties in the Meadows district north of Gold Hill are still operating their furnaces at the reduced price for quicksilver, and claim that they can produce at a good profit with the metal at $50 per flask.

The Nellie Wright group, under lease to R. M. Wilson of Gold Hill, and the Ray & Haff group, under the management of J. G. Davies, of Sacramento, are the only gold properties being operated at present in this district. Several leases have been made recently for important gold properties based on future operations. Among them are the Alice quartz mine, an old producer, three miles south of Gold Hill, leased to H. F. McClellan, W. S. Webb, and C. C. Clark of Medford.

Benjamin Hays and Horten Beeman, experienced local miners, recently took a lease on the Lucky Bart gold mine six miles north, and after two months work extending an old drift, uncovered a large body of $35 ore, 100 ft. below an old pay-shoot which produced $150,000. This property is well equipped with a 10-stamp mill, and has yielded $250,000 since the early 'nineties.

BISBEE, ARIZONA

Fire Fighting in the Shattuck.—Good Ore in the Denn.—Calumet & Arizona's Operations.—Stripping at Sacramento Hill.

The fate of the Shattuck-Arizona mine is a matter of much interest in the Warren district, since the ground in which there is fire on the 800-ft. level has been flooded with water. Except for fire fighting and a small amount of surface work no operations of any kind are under way at this property, and the management holds out no hope for resumption at an early date. Only 50 men are employed. Fire was discovered on about February 15. A cursory examination, all that was possible, showed that No. 1 stope at 800 ft. was the seat of the fire. Work was started at once, and by March 8 the ground up to the 700-ft. level had been bulkheaded. Flooding then was started with water obtained from the town supply and from other companies. This operation was found to be difficult on account of the fact that the fire was in old ground, much broken; but at last reports the water in the shaft stood above the 800-ft. level. It is proposed to flood the mine to 700 ft. if the ground holds water. At least two weeks must pass before water can reach the burning area, according to calculations, and after the fire is extinguished several months will be necessary to pump out the water and prepare the mine for operation.

Although it is questionable whether the management of the Denn-Arizona will decide to continue production at the present rate of 100,000 lb. of copper per month, it is certain that development will be hurried, in view of the recent discovery on the 1600-ft level. This ore is now a carbonate. Work at 1700 ft. has been speeded up, the station having just been completed and driving started. The shaft is down 1800 ft. It is intended to cut a station on that level soon and start driving to develop the ore-zone toward which the 1700-ft. level is heading. Two hundred men are employed at present.

The Calumet & Arizona company is shipping enough ore to its smelter at Douglas to make approximately 3,500,000 lb. of copper per month. As far as information is obtainable there is no intention at present of reducing this output. The force employed has been held constant since the closing of the Cole and Oliver shafts. The policy of returning former employees arriving from Army or Navy to the positions they held before enlisting continues, and for that reason there is a considerable turnover in labor, although the number employed remains about stationary. Development in the Junction mine, where driving toward the Denn-Arizona sideline is under way, continues unabated, though with no results of particular interest. The 1600-ft. drift is in porphyry, while the 1400-ft. level, on which carbonate ores were found several weeks ago, has passed through the mineralized zone and again is in barren country. Advantage is being taken of the present lull in operations to make small repairs and betterments in equipment both in mines and smelters. At the smelter at Douglas, plans are being prepared for a new system of direct overhead charging of the furnaces.

No curtailment in operations of the Copper Queen on Sacramento hill is to be made, it is learned from official sources. Despite the short month of February, 160,000 tons of overburden was removed by the steam-shovel operating there. Neither there nor in any other department has the Phelps Dodge Corporation curtailed its force to any appreciable extent. There have been numerous changes in personnel, it is true, but these have been brought about chiefly by the return of men from the Service. It is peculiar to see men in sailor or soldier uniforms going to work.

The labor situation at Bisbee is complicated by the arrival of many young men who have been discharged from the Army in the training camps of the South-West, but who never before the War worked here or in mines anywhere. As many of these as can be placed are being put to work.

CRIPPLE CREEK, COLORADO

General Notes from Small Properties.

The Reva company, operating the Rose Nicol mine on Battle mountain under a six years lease, commenced shipping this week, moving ore to the loading-station over the new aerial tram. Production from now on will be continuous. The company for two years has been engaged in development and has expended $105,000, but now has a mine. On two levels—the sixth at 800 ft. from surface, and seventh at 1000 ft.—two distinct shoots on the Fluorine vein are under development. One of these is 150 ft. long, the other has been opened 80 ft., so far. The ore in both is of good milling grade. Ore has also been opened on the Rose Nicol at the Roosevelt tunnel-level, 2100 ft. below the collar of the Rose Nicol shaft. This body will be developed later.

Gold production from leased properties of the United company in February showed an increase of 350 tons over the preceding month. The gross value is estimated at $22,700. The Trail mine was the largest producer.

Seven sets of lessees on the Mary McKinney on Raven and Gold hills produced close to 400 tons of milling ore in February.

The Granite company and its lessees are extracting 35 tons daily from its Battle mountain estate.

A 75-hp. electric hoist has been moved from the Katinka mine on Guyot hill to the Nichols shaft on the north end of the El Paso Consolidated's estate.

The Cresson's net return for January amounted to $75,884. Cash in the bank on March 1 was $1,678,526. Shareholders of this company are not required to include the dividends paid during 1918 in their income-tax returns, as the distributions of that year were paid from the sale of ore-reserves acquired prior to March 1, 1913. —— Shareholders of the Portland are not so advised, as the directors consider dividends paid by the company in 1918 to be taxable.

The New Gold Dollar Mining Co. has been incorporated. It succeeds to the holdings of the Gold Dollar Consolidated Mining Co., recently dissolved, and is capitalized with 3,000,000 shares of 5 cents par value. The holdings comprise 62 acres on the western slope of Beacon hill. A. E. Carlton is one of the directors.

Inclusion of the United Gold Mines Co. in a list published by the current issue of 'World's Work' under the caption 'A Thousand Worthless Investments', the final of a series of articles entitled 'Pirates of Promotion' by Louis Gunther, owner of the 'Financial World' of New York, has aroused intense indignation on the part of local shareholders, also at Denver and Colorado Springs. The properties of this company are active, have produced approximately $3,890,000, and shareholders have received $521,800 in dividends. The last was paid in 1917. The February output by lessees was valued at $22,700. A retraction will be demanded.

SILVERTON, COLORADO

Snow Hampers Work in All Branches of Mining.

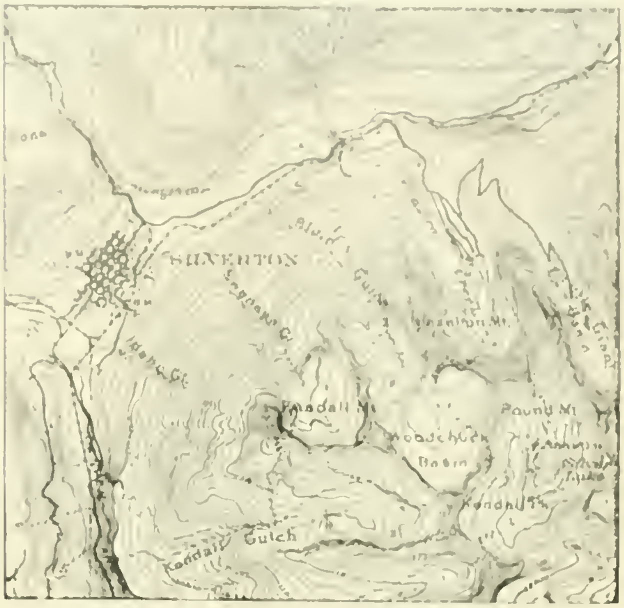
Severe snowstorms, causing numerous slides, have raised havoc with mining and general business in this district. The railroads were blocked, tramways carried away, power-lines cut, and bunkhouses were damaged. Fortunately the slides have run without loss of life, although many narrow escapes have been reported. The Silverton branch of the D. & R. G. was blocked by a huge slide at Elk Park, 9 miles south. Although large crews have been at work trying to move the slide, several days elapsed before traffic was resumed. The first heavy storm began on February 25, accompanied by high winds, and within 24 hours all railroads were blocked. The Silverton Northern had several slides, and after a delay of 4 days, the road was cleared as far as Eureka. The crew then commenced operations on the Gladstone branch, in order to permit the moving of a large quantity of machinery en route to the Gold King Extension mines. The D. & R. G. had difficulty in forcing a way through the heavy drifts on Cumbres pass, on the main line to the east, and 4 days were required to open the road, so that the entire south-western Colorado was cut off from outside communication for this period.

The Anvil Leasing Co. is now in a position to resume shipping from the Coming Wonder mine, on the Emerald lode, and operated under a lease. The entire year of 1918 was spent in development, principally in the driving of a tunnel to cut the main vein. This is now nearing completion, the operators reporting satisfactory results.

The Sunnyside M. & M. Co. is running three shifts at the mine and mill, but a shortage of power resulting from a shortage of water in the reservoirs of the Western Colorado Power Co. permits working of the mill at only half capacity. Snowslides carried out seven towers of the Sunnyside aerial tram, cutting 50 ft. of cable and tearing out the bull-wheel, thus cutting off the ore supply. The Sunnyside is now shipping a car of zinc and a car of lead concentrate daily. The numerous reports as to the purchase of the Silverton Northern lines by the Sunnyside company have not been confirmed so far, but there are many factors that give credence to the report.

The Gold King Extension Mines Co. reports a large enough quantity of good-grade ore on hand to run the mill one shift, but no immediate start is contemplated. The snow has interfered with the plans of the company to such an extent as to defer the opening of the mill to June 1, as a large quantity of milling machinery en route to the mine has been stalled, entailing a delay to construction work. About 70 men are now employed.

The Iowa-Tiger mill tram had two towers carried out by snowslides, causing a shortage of ore supply for the mill, and affecting the output of the Iowa-Tiger and Mayflower properties.



MAP FROM U. S. G. S. FOLIO SHOWING ELEVATION IN SILVERTON DISTRICT, COLORADO.

The general outlook for the next few weeks is not very favorable from a production standpoint, as slides are to be expected for the ensuing month, the snow is heavy and in a condition to run. The weather conditions therefore have a marked bearing on the mining problems of this district.

In Bulletin 685 of the U. S. Geological Survey, just issued, W. W. Atwood discusses the relation of landslides and glacial deposits to reservoir-sites in the San Juan mountains. Most of the reservoirs built and projected are in lakes, but as these lakes are held back by detritus, many of the dams leak and give trouble.

CANANEA, MEXICO

Condition of the Northern States.

Discussion of Mexican affairs occupied a great part of the program of the Arizona Bankers' Association concention, held last week at Nogales, according to Russell Lowry, vice-president of the American National Bank, of San Francisco. Mr. Lowry says that he came away from the convention impressed with the idea that the reports of disturbances in Mexico were greatly exaggerated. According to Nogales bankers and business-men, he said most of the trouble has been in Chihuahua, the States of Sonora and Sinaloa being quiet and peaceable, and, moreover, extremely anxious to be on friendly terms with the United States. The business-men of the border towns sympathize heartily with the people of México. Recently a party from the Chamber of Commerce of Nogales went through Sonora and Sinaloa and were everywhere welcomed. A return excursion is being organized by the Mexican business-men, who will come as far north as San Francisco and will probably be accompanied by border bankers, who are desirous of seeing uninterrupted business relations resumed. Mr. Lowry said further that, from reports of Nogales bankers, there are great possibilities in trade across the border.

THE MINING SUMMARY

ARIZONA

Globe.—In the apex and water suits of the Arizona Commercial v. the Iron Cap, heard at Boston last week, the Court issued a preliminary injunction restraining the defendant from disposing of its assets, but reserved decision on the demurrer, and suggested that counsel confer. The contention of the Iron Cap that only Arizona courts should hear the case is being considered by the full bench.

Jerome.—The Jerome-Superior Copper Co. has been carrying on operations at its extensive property continuously. A mile north of Jerome, under the direction of George Mitchell and G. D. Case, and has not been inconvenienced by the strikes at the other properties. A complete equipment has been erected. The shaft is now over 600 ft. in depth, opening an encouraging showing of chalcocite and copper-iron sulphides. The west drift on the 500-ft. level is in 300 ft. through leached ore and gossan, and is making 40,000 gal. of water daily. An ample duplicate pumping system has been put in. A labor contract has recently been made providing for the sinking of the shaft 200 ft. deeper. This work is now being carried on.

During the shut-down of the United Verde Extension, extensive alterations to the smelting plant are being carried out. Work is continued in the shafts and haulage-tunnel.

The striking of high-grade ore in the Main Top workings of the Jerome Verde has caused a considerable advance in the price of shares. The cross-cut driven to determine the thickness of the orebody has shown it to be 17 ft. wide.

Kingman.—The Rural mine at Mineral Park has been taken over by M. B. Dudley and New York associates. A hoist has been erected and unwatering of the 200-ft. shaft is proceeding. This mine is said to have produced $100,000 in silver from shallow workings.

It is reported that the Record Lode mine has cut its vein at the 500-ft. level, where it is 20 ft. wide, 8 ft. of which assays as high as $28 gold per ton.

Oatman.—The Gold Dust mine is now operating with two shifts. This property, which was worked some years ago by A. L. White, is well equipped to carry on deep exploration. There is said to be a considerable quantity of milling ore above the 300-ft. level.

A. C. Werden, general manager of the Gold Ore Mining Co., announces that the finances of the company are so satisfactory that work is to be resumed soon.

CALIFORNIA

Bakersfield.—Oil production of all fields during February totaled 7,896,442 bbl., against 8,740,471 bbl. in January. The daily average was 65 bbl. ahead of the previous month. There were 8584 producing wells. Stocks on March 1 totaled 28,814,643 bbl., a gain of 77,061 barrels.

Eureka.—Bids were to be received on March 15 for construction of the highway from Orleans in Humboldt to Happy Camp in Siskiyou county. This will be of great benefit to mining.

Grass Valley.—The city council last week ordered the sale of mineral rights under the city cemetery to the North Star Mines for $300. The matter had been pending for several weeks.

Articles of incorporation of the Idaho Maryland Mines have been filed with the county clerk. The incorporators are Roy H. Elliott, Rufus Thayer, and A. B. Seybold, each of whom has subscribed $1000. The company is under the laws of Nevada with the principal place of business at Reno. The capital is fixed at 3,000,000 shares of $1 each.

Plymouth.—The Plymouth Consolidated in January treated 10,300 tons of ore, yielding $61,900 and a profit of $16,300. On the 2450-ft. level, the rise at 350 ft. north is up 113 ft., where 47 in. assays $7.50 per ton. The west drift at 308 ft. north was advanced 46 ft., assaying $8.95 across 24 in. The south drift, 616 ft. east, is out 26 ft. in $3.10 ore across 50 inches. At one point 635 ft. south on the 1600-ft. level, Plymouth Consolidated reports 5 ft. of $18 ore. The last 30 ft. assayed $13 across 55 inches.

Shawmut.—The Belmont Shawmut company expects to resume operations at its mine and mill early in April. The winze below the 2600-ft. level is down 180 ft., in good ore.

Sonora.—The old Dead Horse mine on the east belt above Tuolumne is being opened again, in charge of O. F. Heizer. The State Mining Bureau report on the property of the United Mines states that the Dead Horse has an 1800-ft. shaft, and the Grizzly one of 1000 ft., while the Lady Washington lower tunnel is a 2000-ft. cross-cut connecting with the Dead Horse shaft. The Dead Horse vein was extensively worked through the tunnel and shafts.

COLORADO

Georgetown.—The 300-ton flotation plant of the Colorado Central company is working full time concentrating dump material. The product—5 to 10 tons daily—assays 100 oz. silver per ton. Work is also under way in the old Marshall tunnel.

Idaho Springs.—The Randolph Gold M. M. & T. Co. has taken over the Empire T. & T. Co.'s property at Empire. W. A. Snyder is general manager. The Empire has been tied-up in litigation for some years. According to a recent report, there is estimated to be 1,773,000 tons of $6.35 ore available, which should yield $2 per ton net. A new mill is contemplated.

Leadville.—The Yak company has reduced wages by $1 per shift, effective April 15. This is considered to be the forerunner of a general cut in the district.

Norwood.—The Primos Chemical Co. has lost its blacksmith-shop by fire, adding to the heavy loss sustained three weeks ago when the mill was consumed. The cause has not been ascertained.

The Radium Company of Colorado operated continuously during the winter with a large force, and has been hauling ore from the mines in the Long Park district. At present, six 6-horse teams, two 4-horse teams, and three 2-ton motor-trucks are busy hauling ore.

Ouray.—The Camp Bird company office in London recently issued the following circular:

"In view of the very interesting work being carried out in the east drive from the tunnel at the Camp Bird mine, the directors think the shareholders will be glad to have the following summary in non-technical language of the recent cables which have been published, showing what has so far been accomplished. The cable information has been somewhat amplified by letters from the mine, and the directors are thus enabled to give additional general information to the shareholders.

"It may be useful to recall that the tunnel intersected the Camp Bird lode almost exactly at the point predicted by our engineers. At the point of intersection no value was encountered, which is what was to be expected from the conditions existing in the old workings above this point. Having thus proved the existence of the lode, its exploration was at once undertaken by a drift east. At about 1500 ft. from the point of intersection a run of high-grade ore was encountered, which seems to correspond with the body of ore extracted from workings on the old 9th level above it. Further driving on the tunnel level disclosed a small body of ore, the value consisting largely of silver. After passing through these two runs of ore, the east drift was continued in low value till at about 1950 ft. from the point of intersection another run of ore of good value was entered, and from this point to the present face appearances are very encouraging. This last-named run of ore probably corresponds with the important body of ore (which yielded a profit of some £500,000) which was extracted from the No. 3 shaft workings at and above the old 9th level, this being some 450 ft. above the present low-level tunnel. The manager has no hesitation in believing that the lode encountered—and driven upon for about 2000 ft.—from the tunnel is the true Camp Bird vein with known characteristics established in the old workings. The mineral hematite has made its appearance in the tunnel, and its presence seems to be an indicator of the existence of value in this section, as it always was in the upper workings.

"The directors conveyed to the manager their wish that connection should be made between the tunnel-level and the 9th level, by means of a raise (at the 1500-ft. point, where high value was found) simultaneously with pushing ahead of the east drift. He, however, has pointed out the difficulties, owing to insufficient ventilation, of doing this work on the two points at the same time, and further information is awaited hereon, with final decision of the manager as to the best policy. In the meantime exploratory work has been carried out by means of two raises about 30 ft. apart in the neighborhood of the two runs of ore at the 1500-ft. point. These raises have already passed through 13 ft. of good-grade ore, revealing a large vein, but the total width of the ore here is not yet determined. From the tunnel three cross-cuts also are being put in 50 ft. apart; notwithstanding this, the manager finds the results on the tunnel-level under the main No. 9 level ore-shoot (about the present end of the drift) so encouraging that he strongly recommends exploration at this point. In a letter just received from the manager describing existing conditions above the tunnel-level he says: '* * * vein conditions otherwise correspond with those on 9th level a little farther west, leading one to believe that probably the conditions existing in 9th level, at parallel 1450, are to be repeated in this level; and it was east of this point that we had the best stope in the 9th level'."

Rico.—The Hiawatha vein in the Group tunnel has been leased to Victor Lee. A large quantity of low-grade dump ore is being worked over.

The Syndicate M. & M. Co. has started to drive a cross-cut tunnel from the Group tunnel with the objective of cutting the Shouldn't Wonder, McKelvie, and Rider veins, opened by the main Group tunnel several years ago. The operators expect to cut these veins after they have passed through the large cross-veins known to exist in Newman hill. Rapid progress is being made in driving, 4½ ft. per shift; machine-drills are in use. Power is supplied at minimum cost, as the local power company is owned by the operators. An electric sinking pump is being put in to handle the water that accumulates in the Smuggler south drift, in the Syndicate mine. A section of the company's holdings has been leased to A. Hay and A. S. Herron, who will drive a cross-cut to cut into a 'split' of the vein.

The Rico Wellington company has uncovered a good body of ore in the Mountain Spring tunnel. Copper ore has been opened in the Wellington tunnel. Large copper precipitation tanks are being erected in the 57-ft. level, in order to recover the copper that has formerly been lost in solution.

The Rico-Argentine, Marmatite lease, is again shipping ore, two cars having recently been billed out. There are, however, no extensive operations under consideration at this time.

Telluride.—The Belmont Wagner company expects to resume operations at its mine and mill during April.

IDAHO

Burke.—The auxiliary power-plant of the Federal M. & S. Co. was burned on March 9. The loss is estimated at $20,000. Power is also supplied by the Montana Power Co., so work will not be interrupted.

Kellogg.—The Caledonia company pays 1 cent per share on April 5. This is $26,050 and makes a total of $3,777,250.

Wallace.—The Miners Trade School recently started here under the auspices of the University of Idaho is making good progress, according to F. A. Thomson, dean of the School of Mines of the University. The work is proceeding along entirely novel lines, the class-room being the 1400-ft. level of the Morning mine, where men just returned from army service are being taught practical mining. The work is being carried on by the State in co-operation with the Federal Board for Vocational Training, operating under the Smith-Hughes Act. The School has taken a contract to drive a drift at a price per foot, and the surplus, after paying for explosives, will be distributed pro rata among the pupils.

MISSOURI

Joplin.—Production of the Tri-State region last week was as under:

State	Blende, tons	Calamine, tons	Lead, tons	Value
Kansas	1,324	...	611	$91,557
Missouri	1,312	77	207	78,315
Oklahoma	5,440	...	1,293	302,218
Total	8,076	77	2,111	$472,090
Average value ...	$41	$27	$61	

The demand for ore is about normal.

The Badger M. & D. Co. has started its new 250-ton mill. In three shafts ore is found, at 96, 155, and 185 ft. depth, respectively. The 'run' of ore is 1280 ft. long. T. E. Forester is president.

MICHIGAN

Houghton.—Ahmeek pays $1 per share on March 31, equal to $100,000.——Osceola pays $1, or $100,000, on the same date. These are both reductions of $1 per quarter. During 1918 the Osceola produced 15,919,647 lb. of copper at a cost of 17.37 cents per pound. Ore yielded 13.3 lb. per ton. Dividends totaled $961,500. There was 1,194,967 tons of ore milled, a decrease of 42,838 tons.

Mohawk in February produced 1,146,493 lb. of copper, a trifle less than January, but much over the average for 1918.——Wolverine yielded 440,905 lb., larger than any month of last year.

Mass Consolidated Mining Co. in 1918 made a loss of $25,598, but the year ended with cash assets totaling $295,773. Receipts amounted to $796,638.

Comparison of results in the last three years is as follows:

	1918	1917	1916
Ore hoisted, tons.......	216,431	285,769	318,968
Ore stamped, tons.......	196,456	244,671	287,900
Refined copper, lb.......	3,403,827	3,984,616	4,752,588
Copper per ton, lb.......	17.33	16.29	16.51
Cost per pound, cents....	23.82	19.81	15.37

The approximate tonnage of ore from the three mines of the Copper Range Co. in February totaled 77,954 tons: the Champion 45,700, the Baltic 20,251, and the Trimountain over 12,000 tons.

MONTANA

Butte.—The Butte Copper & Zinc Co.'s report for 1918 (really for 13 months) shows that $669,328 was received from sales of ore. The net income, taxes not deducted, was $619,986. Current assets total $630,056, and liabilities $154,798. Dividend No. 1, on July 2, absorbed $300,000. Ore shipments were 32,293 tons of zinc and 71,364 tons of manganese. Mining of the latter was stopped in November, when the daily output was 375 tons. Much of this ore was sent to the ferro-manganese plant of Anaconda at Great Falls, now closed. Attention is now devoted to zinc ore.

Anaconda is extracting over 2000 tons of 15% zinc and 7-oz. silver, ore from its Emma mine, mostly from 800 ft. The manganese workings are being kept open, as the company believes that it may eventually be able to sell its Great Falls ferro-manganese as far east as Chicago.

NEVADA

Austin.—The main tunnel at the Austin Nevada has penetrated Lander hill for 600 ft., and is expected to reach the main vein within 350 ft. On the surface the body is 80 ft. wide, carrying silver and gold. At 600 ft. east of the main workings a tunnel is advancing to cut a vein showing a width of 58 ft. at the surface. At 800 ft. south-east of the main tunnel 12, parallel veins have been intersected by a cross-cut-tunnel, which is approaching a vein that assayed high in silver near the surface. One of the veins assays $35 per ton in gold. This tunnel is opening a number of small rich veins, and is being extended to intersect the main orebody 150 ft. below the main workings. The Hiawatha tunnel has been cleaned out and track laid preparatory to mining ore exposed in old workings. H. G. Richardson is manager.

High-grade silver-gold ore has been uncovered on the 200-ft. level of the Austin Dakota, and a winze from this point is down 50 ft. in ore. A small pump has been put in to handle water recently appearing in the shaft. Driving both ways is proceeding on the San Jose vein, and extraction of ore from it will be started soon. Charles E. Littrell is manager.

Re-opening of the Diana shaft of the Austin Manhattan has been delayed by a heavy flow of water on the bottom level. The shaft has been closed for 30 years, and is being repaired to facilitate mining of ore from old workings. William Marshall is superintendent.

The drift from the second level on the Warner, in Washington canyon, is exposing milling ore for the full width, with several shoots assaying 40 to 300 oz. of silver. A large tonnage of rich ore has been placed on dumps for shipment as soon as roads permit. From the third level, a drift is advancing to cut the orebody 150 ft. below the second level. The mine is owned by Mrs. Rose Warner and is in charge of W. M. Thacher.

Carson.—The biennial report of the State Assayer and Inspector, F. C. Lincoln, for 1917-1918, is to hand. Under the Nevada statutes of 1917 this officer was appointed. Upon request of any shipper to any Nevadan purchaser, it becomes the duty of the State Assayer to take charge of the shipment in the interest of the owner and see that it is properly sampled and assayed. The fee for this is 25 cents per ton on lots over 50 tons, and actual cost of sampling on smaller lots. From August 1, 1917, to December 1, 1918, this Department reported on 189 lots of ore. These were from 75 different operators in 28 districts, sent to three buyers. The total was 5308 tons. The Western Ore Purchasing Co. at Hazen received 187 lots, the others being one each to the Thompson plant of the Mason Valley Mines Co., and the West End Consolidated at Tonopah. Companies purchasing ore in Nevada during the period were the Elko Prince Leasing Co. at Midas, 680 tons; Goldfield Consolidated, 799 tons; Mason Valley, 275,625 tons; Nevada Consolidated, 413,719 tons; Silvermines Corporation, 4448 tons; Tonopah Belmont, 28,704 tons; Union Consolidated, 14,647 tons; West End Consolidated, 21,234 tons; and Western Ore Purchasing, 48,442 tons. The Department has 761 operators on its mailing-list, but only 10% have patronized it. Some of these are large shippers employing their own ore-checkers, while some attend to sampling themselves; but there must be many who might employ the State Assayer. In order to ascertain how the Department was viewed, a questionnaire was sent to 75 past patrons. Generally, the answers showed satisfaction, but that the facilities were not sufficiently advertised.

Goldfield.—It has been announced that, except minor details, an agreement has been made granting the Silver Pick Consolidated a sub-lease on the southern half of the Mohawk No. 1, north third of the Mohawk No. 2, and north fourth of the Combination claim of the Goldfield Consolidated, now under lease by the Goldfield Development Co. The leased territory includes over 20 acres adjoining the Silver Pick on the east and south-east. Work has been in progress for a long period on the 1250 and 1305-ft. levels of the Silver Pick, and recently the most promising formation found in the mine was opened at the latter depth in a seam, believed to indicate that the cross-cut is nearing a vein apexing far to the west of Silver Pick ground. Ore has not been found, but the ground is heavily mineralized. A cross-cut was started recently from the 700-ft. level. This will continue 120 ft. to the western boundary of the Mohawk No. 1, and into this claim to cut the Silver Pick vein in leased territory. There is also under consideration a plan to cross-cut on the 300-ft. level to explore the Combination vein north of the rich ore-shoot mined in the early days of Goldfield by the Kalfus, Begole, and Sheets-Ish lessees.

Goodsprings.—By an explosion at the Yellow Pine last week, the power-plant, hoist, and engine were badly damaged. The manager, M. P. Kirk, considers that little of the machinery is worth salvaging.

Mill City.—The tungsten mines and mills in this district are closed, due to the uncertain market. An immense quantity of ore has been developed.

Round Mountain.—The Round Mountain company expects to sluice 150,000 yards of $1 gravel this coming season. There has been a heavy snowfall, which has packed well, ensuring plenty of water.

Tonopah.—Production of the district last week was 7351 tons, valued at $124,967. Some February yields were as under:

Mine	Tons	Silver, oz.	Gold, oz.	Profit
Belmont ...	8,549	101,129	1,064	$50,061
Extension ..	8,628	111,384	1,094	45,957
Mining	4,500	76,775	845	39,465

The Belmont is to distribute 10 cents per share, $150,000, on April 1. The company is to resume operations at its Colorado and California properties in April.

NEW MEXICO

Santa Fe.—A substitute bill for the mining bills before the State Legislature has been consented to by all concerned. The operators agree during 1919 and 1920 to be taxed on average output for 1916, 1917, and 1918, regardless of what the future output may be, provided that if the coming output exceeds the old basis the tax is to be on the larger future output. The compromise may yield the State between $600,000 and $700,000 net increase in taxes in the next two years

OKLAHOMA

Miami.—The Oklahoma Ore Storage Association has issued a booklet describing its organization and showing views of the ore-storage warehouse at Picher. The project was described by J. McNicholas in the 'Press' of March 1

MILLS AT CARDIN, OKLAHOMA.

Picher.—One machine-man and a helper in the Cosmos mine near here broke 1159 cans (1000 lb. capacity each) of ore last week, according to the Joplin 'Globe'. W. Smith and F. Greishaber of the Blue Bird mine at Commerce considered that this record was beaten at the mine where they are in charge, as one driller and a helper, with Sullivan and Leyner machines, broke 2522 cans of ore, varying from 1250 to 1650 lb. each. For two months, 2000 cans per week was the average, with one machine. Four shovelers moved 414 cans in 6½ hours. [At an average of 1450 lb. per can, each man shoveled 75 tons per shift.]

OREGON

Sumpter.—The Continental Mining Co., 23 miles from here, has opened high-grade gold-silver ore. There is 4 to 16 in. of rich ore in a vein 18 to 36 in. wide. The ratio of the metals is 3:1. A 20-ton flotation plant is being erected. The elevation of the mine is 6940 ft. W. W. Robbins is president.

TEXAS

Austin.—The Governor has signed the new bill imposing a 1½% gross tax on oil production in this State. It is estimated that the annual income will amount to to $2,000,000.

Thousands of owners of Texan lands are relieved by the decision of the State Supreme Court that all minerals upon public lands sold by the State under the Act of 1883 went to the purchaser. What makes the case specially interesting is that several million acres, in the western part of the State, where exploration for oil is now going on, were sold under the law that was being contested. If the decision of the Court had upheld the contention of the relator in the case, oil and other minerals that are now being produced upon land sold under the law of 1883 would have passed to the ownership of the State of Texas.

The Dudley mining law bill was advanced in the House to the third reading, so it is expected to pass when finally considered. The Senate has already passed the measure. Its enactment is expected to aid development of mines. Oil, gas, and coal are not included.

UTAH

Bingham.—The Bingham Mines Co. in 1918 made a profit of $164,272, plus $167,458 from subsidiaries, a total of $331,730. Dividends totaled $375,000. Current assets amount to $168,248, mostly cash

Utah Consolidated paid 25 cents per share, $75,000, on March 25

Dugway.—The Metal State Mining Co., Henry Schepers, manager, has decided to erect a 50-ton concentrating plant The ore carries copper and silver

The Metallic Hill and Lucky Star mines in this district of Tooele county are being worked continuously, the former having a carload of high-grade silver lead copper ore sacked.

Lark.—The Ohio Copper Co. closed its mine and mill on March 10. On hard ore, the flotation plant gave a high recovery; but on soft ore it was low.

Park City.—The Judge M. & S. Co. pays 12½ cents per share, $60,000, on April 1. The total is now $2,370,000.

The Daly West Mining Co. during 1918 sold ore, concentrate, and tailing, and received royalties from lessees totaling $184,592. Other income made a total of $217,564. The balance on January 1, 1919, was $23,623, against $30,208 a year ago. The treasury has now $163,000, including the new capital. All matters being cleared up, systematic exploration is to be carried on.

Salt Lake City.—In the prolonged argument in the Legislature over the Mine Tax Bill, on March 15, conferees of the House and Senate agreed to recommend that the assessment be fixed at three times the net proceeds of mines. This upheld the stand taken in the House, and the report was offered in the Senate on that date. The Senate finally passed the measure, but it is said that the Governor will veto it, as the bill did not contain the words "not to exceed" before "three times their net proceeds." This was the principal cause of the dispute between the House and Senate.

Governor Bamberger approved of the mine-tax law on March 21.

Tintic.—The Tintic Standard pays 8 cents per share on March 29, equal to $93,976. This makes $492,849 to date.

VIRGINIA

Midvale.—Advice from the Irish Creek Tin Mines company, which is prospecting a tin deposit in Rockbridge county, according to the U. S. Bureau of Mines, is to the effect that the orebodies, so far, are disappointing, both as to size and metal content. Of 19 samples taken, 14 gave blank returns, and the remainder an average of less than 1.5% tin.

WASHINGTON

Chewelah.—The United Copper Mining Co. during 1918 reduced its indebtedness of $74,919 to $39,879, but by April 1919 this would be wiped out. The revenue last year was $282,965, of which $18,674 was operating profit. Depreciation, taxes, etc., reduced this to $18,174. The output was $66,180 tons of ore, yielding 987,524 lb. of copper and 142,005 oz. of silver. When shipments of the new high-grade ore commences, profits are expected to be at least $30,000 monthly.

Northport.—The Electric Point company pays 3%, or $23,790, on April 1. The total will be $277,575.

Republic.—The Lone Pine-Surprise mines have been acquired by the Northport Smelting & Refining Company.

CANADA

British Columbia

Ainsworth.—The Florence Silver Mining Co. pays 1½ cents per share, $17,650, on April 20. The total is now $35,300. Monthly dividends are now to be paid. Two feet of galena, assaying 70% lead and 22 oz. silver, has been opened at a depth of 350 feet

Anyox.—Granby Consolidated pays a dividend of 1½%, $187,500, on May 1.

Hedley.—The Hedley Gold Mining Co. paid 10 cents per share, $12,000, on March 31.

Nelson.—The Kootenay Gold Exploration Co., which operated the Granite-Poorman mine, is expected to resume operations shortly. Action has been taken toward paying off local creditors, and it is expected that the company named, which bonded the property from the old Kootenay Gold Co., will commence work without delay.

Victoria.—The sum of $207,523 has been expended by the Provincial government in construction of roads, trails, and bridges to mineral claims in British Columbia, since the present administration took charge late in 1916.

The development of a number of promising copper properties on Vancouver Island is to be continued this summer. Generally speaking, the policy of operators appears to be to proceed with the blocking out of ore to be ready for the re-adjustment of the market.

Ontario

Boston Creek.—The Miller Independence company is to sink a central vertical shaft to a depth of 600 ft. to intersect the vein, which dips at 50 to 60°. The encouraging results by diamond-drilling in the Cotter property adjoining are important to the Independence.

Kirkland Lake.—Lake Shore produced gold worth $45,162, from 1725 tons, in January. The estimated yield since the plant started in March 1918 is $515,000.

The U. S. Civil Service Commission, Washington, D. C., announces open competitive examinations by April 15 for junior metallurgist and junior mining engineer. At present there are two vacancies in the position of junior metallurgist at Seattle, each at $1500 per year, and two vacancies in the position of junior mining engineer, one at Seattle, at $1500, the other at Pittsburgh, at $1200. Competitors will not be required to report for examination at any place, but will be rated on education, training, and experience, 80; and publications, reports, or thesis (to be filed with application) 20. Under the first subject competitors will be rated upon the sworn statements in their applications and upon corroborative evidence adduced by the Commission.

The American Welding Society has been organized as a merger of the Welding Committee of the Emergency Fleet Corporation and the National Welding Council, also including several engineering societies. H. C. Forbes is secretary at 29 West 39th street, New York, the Engineering Societies building.

PERSONAL

Note. The Editor invites members of the profession to send particulars of their work and appointments The information is interesting to our readers.

D. P. Mitchell has arrived at Vladivostok.

B. C. Austin left for Teguchigalpa, Honduras, on March 22.

A. W. Stickney has moved from London to Galesburg, Illinois.

Thomas J. Jones is here on his way from London to Siberia.

E. M. Hamilton has returned to San Francisco from Parral, Mexico.

Denis Stairs, Captain in the B. E. F., was in Vancouver last week on his return from Siberia.

G. D. Delprat, manager of the Broken Hill Proprietary, has arrived from Australia on the 'Ventura'.

J. L. Zimmerman, of Columbus, Ohio, was in San Francisco on his return from Hermosillo, Mexico.

Drummond MacGavin, Captain in the Field Artillery, has returned from France to his home in San Francisco.

Fred. G. Farish is consulting engineer with the New England Exploration Co., with headquarters at Denver.

W. H. Blackburn, general manager for the Tonopah Mining Co., is in Nicaragua at the company's Eden mine.

John C. Greenway, Lieutenant-Colonel, has returned from Europe and is at Ajo, Arizona, recovering from the effects of gas.

Robert E. Montgomery, formerly in Denver, passed through San Francisco on his way from Victoria, B. C., to Texas.

Edward Steidle, well known from his mine-rescue work for the U. S. Bureau of Mines, lost an eye during the closing days of the War.

Harry Lee has retired from the superintendency of the Silver King Consolidated at Park City, Utah, and is succeeded by **Norman Blye.**

Courtenay De Kalb sailed by the 'Patria' for Spain on March 25. He goes on a special commission for the U. S. Department of Commerce.

G. W. Heintz, of the U. S. Smelting, Refining & Mining Co., is at Kennett, California, inspecting the properties of the Mammoth Copper Company.

Ira Joralemon, Major in the A. E. F., has returned from France to Berkeley and shortly will resume his duties as geologist to the Calumet & Arizona Copper Company.

J. Mackintosh Bell, Lieutenant-Colonel in the British Army, will resume his professional work as mining engineer. He has returned from Siberia and is now at Almonte, in Ontario, Canada.

F. R. Carroll, district manager (San Francisco) of the B. F. Goodrich Rubber Co., left on March 24 for the Orient on a special mission for that corporation. **W. T. Powell** will be acting manager in the interim.

John G. Kirchen, connected with many mining companies in Nevada, was unfortunate enough last week to have his foot crushed in the White Caps mill at Manhattan, rendering amputation necessary.

THE POSITION OF ASSOCIATE EDITOR ON THIS PAPER IS VACANT. APPLICATIONS FOR THE APPOINTMENT ARE INVITED.

Frederick Hobart, for more than twenty years on the editorial staff of our New York contemporary, died at Flushing, New York, on March 9. He was born in New York in 1842. He served in the Civil War and was a man of good sense, great kindness, and long-continued usefulness

THE METAL MARKET

METAL PRICES

San Francisco, March 25

Aluminum-dust, large and small lots, cents per lb.	65—70
Antimony, cents per pound	8.00
Copper, electrolytic, cents per pound, in carload lots	15.25
Lead, pig, cents per pound	5.50—6.50
Platinum, per ounce	$100
Quicksilver, per flask of 75 lb.	$68
Spelter, cents per pound	8.00
Zinc-dust, cents per pound	12.50

EASTERN METAL MARKET

(By wire from New York)

March 24.—Copper is more active and stronger. Lead is active and easier. Spelter is dull though steady.

SILVER

Below are given official (not Government) quotations, in cents per ounce, of silver 999 fine. In order to make prompt settlements with smelters and brokers, producers allow a discount from the maximum fixed price of $1.01½, hence the lower price. The Government has not fixed the general market price at $1, but will pay this price (as from April 23, 1918) for all silver purchased by it. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the current rate of exchange. On August 15, 1918, the Treasury announced that the maximum price was fixed at $1.01½ per ounce. The British government fixed its maximum at 49½ pence, on September 2, but on November 12 this was changed to 48¾, on December 13 to 48 7/16, and in February to 47¾ pence.

Writing on March 6, Samuel Montagu & Co. of London said that the silver market continues quiet and steady in character. The Shanghai exchange fell to 4s.6½d. ($1.09) the tael. The Indian financial statement presented on March 1 reveals the inconvenience—to use no stronger word—caused by an insistence on metallic money. The word 'money' is used advisedly—and not currency—because the bulk of the silver coin is required for hoarding (notes being perishable) rather than currency. The circulation of one rupee notes (1 rupee = 32 cents) has risen to Rs. 90,000,000, but this amount—though encouraging—is slight, compared with the heavy absorption of coin recorded by the Indian currency returns notwithstanding extremely large remittances of silver from America. Obviously the hoarding habit is still in full swing. The same conditions, though in a much less degree, obtain in West Africa, where an addition of £1,388,100 in silver coin was made in the year ended June 30 last. The fact is, that the natives of these populous countries are seeking to acquire possession of silver in excess of production and other sources of supply.

The American Zinc Institute, in its campaign to increase the use of zinc is advocating spelter for rail-bonding purposes. One of the largest railroad companies recently made a considerable purchase of spelter for use in the manufacture of its Nicholas joints. Engineers in charge of bonding operations report that, viewed from price and adaptability standpoints spelter is unexcelled for such work. Zinc is comparatively plentiful and relatively cheap, and in many directions it is satisfactorily taking the place of more expensive metals.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

ORES (New York)

Manganese-Iron Alloys.—While most producers continue to quote $200 per ton, delivered, for 78 to 80% alloy, it is understood that this level will be reduced in the near future. They are taking no business at this price. It is stated that 80% ferro, re-sale material, has sold in carload lots as low as $130 per ton, delivered, and also that one producer has sold 75 to 77% alloy at the same figure. Spiegel, 16 to 18%, is quoted nominal at $40, furnace, with the higher percentage quoted at $45.

Molybdenum.—Quotations continue nominal at 80 to 85 cents per pound. The market is dead.

Tungsten.—There is little change and virtually no business reported. Quotations representing real values are impossible. This is also true of ferro-tungsten. Imports of ore into the United States in 1918 were 10,363 long tons, of which 1200 tons came from Japan, 500 tons from Argentina, 4000 to 5000 tons from China, and the remainder from Bolivia.

Regarding the War Minerals Relief Bill the California State Mining Bureau says that all persons whose claims are judged worthy will receive questionnaires and will be required to give exact date on which they began to produce or to prepare to produce chrome, manganese, pyrite, or tungsten. If they have had any correspondence in any form from the Department of Interior, War Industries Board, War Trade Board, Shipping Board, or Emergency Fleet Corporation, they will be required to submit proof. If their activities resulted from any oral statements of representatives, officers, or agents of any Government department, they will be required to state the circumstances and also offer proof. Whatever form of inducement was made to them or whatever circumstance lead them into the production of war minerals must be given in detail. They must be prepared to furnish affidavits if required.

Eastern Metal Market

New York, March 19.

Lack of buying is the chief characteristic of all the markets, but the price tendency may be regarded as fairly firm.

Antimony has declined slightly.

Copper prices have changed but slightly in the last week in spite of little buying.

Lead has become dormant, but prices are firm and unchanged.

Tin continues featureless and stagnant.

Zinc has a little better inquiry, but sales are small and the price tendency easy.

ANTIMONY

Wholesale lots of Asiatic metal for spot or early delivery are quoted at 6.62½ to 6.75c., New York, duty paid, with demand light. The jobbing market is about 7c., New York, duty paid.

ALUMINUM

There is no change in the situation. No. 1 virgin metal, 98 to 99% pure, is quoted at 29 to 31c. per lb. in wholesale lots for early delivery. Re-melt metal of the same analysis is about 2c. per lb. under this.

COPPER

The market is quite lifeless, demand from domestic or foreign sources being still very small. It is estimated that sales during the past week have been not over 12,000,000 lb., one authority placing those for the previous week at over 22,000,000 lb.—both insignificant figures when compared with normal markets. The past week has not witnessed any severe fluctuations in prices. These have ranged between 14.50 and 15c., depending on the seller and the quantity sold. The large producers claim that they are holding firmly at 15c. for electrolytic copper, but it is believed the smaller ones have sold at 14.50 to 14.75c. An attractive inquiry, it is believed, would bring a quotation as low as 14.75 to 14.87½c. from the larger makers. We quote the market for electrolytic copper at 14.87½c., New York, with Lake copper nominal at 15.25c., New York, demand for both being light. An interesting export inquiry comes from a British consumer asking for 2000 long tons of selected copper (99.75%) for which he offers £60 per ton, for delivery over the next 12 months. Considerable interest is directed toward the return in a week or so to this country of the committee of the Copper Export Association, which went to Europe to investigate the future European demand for copper. The quantity of copper salvaged from the battlefields of France is reported from British sources as so large that licenses for its exportation have been authorized.

IRON AND STEEL

Keen interest is manifested in the meeting in Washington today between steel makers and the Redfield Industrial Board regarding a lowering and stabilizing of prices. No one knows what is to be the result of this important meeting, and opinions vary as to what is best. Whatever price changes result, the week's market, scant as business has been, has further emphasized the downward tendency. There are widespread reports of sales of basic iron at $25, furnace, or a reduction of $5 per ton; one of these reports has been denied. The total involved was 15,000 tons. In semi-finished steel there is reported a sale of slabs to an Eastern mill at $40, while in heavy sheets there have been concessions of $6 per ton from prices early in the year. It is still true that the U. S. Steel Corporation's steel output is relatively larger than that of the independents, due to the carrying over of considerable tonnages that were put on the books in 1917. The total of the January and February steel bridge and building work put under contract was only 44,000 tons out of a two year's capacity of 2,160,000 tons, indicating the slump in building activity.

LEAD

After the demand of a week or two ago the market has turned extremely dull, but it is steady with little inquiry appearing. We quote both the outside (independents) and the other market (A. S. & R. Co.) firm at 5.25c., New York, or 5c., St. Louis, for early delivery. It is stated that an attractive firm offer would bring a concession from outside producers, but this has not been tested. One dealer said he would dislike to offer 5.15c., New York, unless he really wanted the metal. Production is generally estimated at a very low ebb, and this fact is cited as a prediction of a strong market some time. There is less expectation of an advance in quotations by the leading interest that hung over the market for some weeks.

TIN

It is the same old story—the market is stagnant and still under Government restrictions, and is featureless. The official price for the allocated metal still holds at 72.50c., New York, for Straits tin, and there is practically none available under this level. The fact is still emphasized that such tin could be purchased for future shipments from the Straits at around 52c., but this is impossible as imports are still prohibited except to the United States Steel Products Co., which organization is not buying at present, with the large stocks of allocated metal still on its hands. The only phase of interest is the fact that some consumers are paying more attention to the question of buying tin soon for future shipment, so as to have it nearer at hand as soon as the American import restrictions are removed. But this greater interest has not yet developed into any marked buying movement. General opinion is to the effect that all import restrictions will be removed by June 1, but this may be a mistake. The American Smelting & Refining Co.'s output of tin from Bolivian concentrates in 1918 is announced as having been 19,868,000 lb., compared with 12,130,000 lb. in 1917. Tin arrivals so far in March have been 1425 tons, all at Pacific ports. Spot Straits tin was quoted yesterday in London at £239 per ton, against £243 a week ago.

ZINC

Many consider that the zinc market has really touched bottom despite the apparent fact that production and stocks have not declined as much as the situation really has warranted. A better demand is reported thus far this week, but it has not developed into much buying. The feeling is that with an adjustment or stabilizing of steel prices next week will come a buying of steel sheet-bars by galvanizers, and as a result a buying also of spelter, as it is believed that galvanizers' stocks are low. The tone of the market is at least better than in the past few weeks. Prime Western for March, April, and May delivery is quoted at 6.12½ to 6.15c., St. Louis, or 6.47½ to 6.50c., New York.

Estimates of the production of portland cement in 1918 compiled under the direction of Ernest F. Burchard, of the U. S. Geological Survey, show a marked decrease in the total output; in fact, the output was the lowest since 1909. The estimated shipments in 1918 amounted to 71,645,000 bbl., valued at $113,910,000, compared with 90,703,474 bbl., valued at $122,775,088 in 1917, a decrease in quantity of 21% and in value of 7.2%.

Note: Companies not included in the above list are requested to submit details. Changes in capitalization and new dividends will be entered on receipt of the information. This table will be published quarterly.

Company Reports

NATOMAS COMPANY OF CALIFORNIA

Property: 10 dredges, 2 machine-shops, and 2 rock-crushing plants at Natoma and Oroville, and extensive agricultural lands in Sacramento county, California, known as Reclamation Districts 1000 and 1001.

Operating Officials: Emery Oliver, general manager; L. D. Hopfield, in charge of dredges at Natoma; P. C. Knapp, secretary.

Financial Statement: to present this briefly for 1918 is impossible, owing to the complexities of the land business, but the following gives an idea of the position; the present report being mainly a retrospect or summary of operations since the reorganization:

Indebtedness at end of 1914 exclusive of bonds, interest, and stock of Natomas Consolidated	$3,698,751
Indebtedness at end of 1918	$160,943
Mortgage and bonded debt	10,869,485
Current liabilities	200,943
Capital assets	16,061,800
Securities at end of 1918	1,074,244
Current assets ($367,315 cash)	1,439,735
Total of last two items	$2,533,979

Dredging: during 1918 the boats dug 24,172,626 cu. yd., recovering gold worth $2,008,966, of which $746,119 was profit. In five years the total recovery was $11,517,170, giving a profit of $5,669,061. All of the dredging profits are absorbed in paying bond interest. In 1915 it was estimated that there was 216,000,000 cu. yd. of pay-gravel, but additions have been made, so that after 128,000,000 yd. of the original area have been dredged, there are 182,220,000 yd. still available, plus 40,000,000 yd. if pre-war costs prevail before this ground is reached. The apparatus placed on the boats to save fine gold has recovered $107,000 net, most of which would have been lost under previous methods. Four boats must be reconstructed during the next five years so as to complete the dredging operations.

Rock Crushing: in five years, the plant at Fair Oaks produced 1,733,944 tons of crushed rock, 198,944 tons of washed gravel, and 275,724 tons of screened gravel; and the plant at Oroville 451,364 tons of crushed rock, and 458,016 tons of screened gravel. The crusher products and field gravel are sold throughout the State.

Land Department: reclamation work has cost $4,480,500 to date, inclusive of accrued interest, etc. In district No. 1000, there have been sold 10,147 acres for $2,889,446; and in No. 1001, 1292 acres for $343,537. All of these properties are being irrigated, provided with roads, and generally prepared for sale.

DE BEERS CONSOLIDATED MINES

During the year ended June 30, 1918, this company sold diamonds amounting to £4,327,649 ($20,770,000). The profit was £2,771,515, of which £1,990,000 was distributed to shareholders. From 5,843,099 loads (1600 lb. each) of 'blue' ground, the average yield was 0.27 carats per load. Reserves are 22,000,000 loads.

E D I T O R I A L

REFERRING to the idea of establishing a Department of Mines in the national administration at Washington, a subject on which we published recently an interesting utterance by Mr. John F. Davis, we note that an agitation is afoot in England to organize a Mines Department for the United Kingdom.

FORMERLY, and for many years before the War, the prices of copper and lead showed a ratio of 3.4 to 1. Today that proportion does not obtain, because the price of copper was pushed to an extravagant figure during the first two years of the War, before the Government took a hand in price-fixing. It was our opinion then, as now, that the big copper producers showed lack of sagacity in encouraging an excessive price for the metal.

WE have received a few copies of the regulations prepared by the War Minerals Relief Commission, which has been appointed to adjust, liquidate, and pay claims arising out of losses suffered by persons, firms, or corporations producing, or preparing to produce, manganese, chrome, pyrite, or tungsten. We have also a few copies of the questionnaire to be used by claimants in filing claims for the consideration of the Commission. These can be obtained gratis from the Commission, whose address is Suite 2131, Department of the Interior Building, Washington, D. C.

STERLING exchange has dropped to $4.59 because the peg that fixed it at about $4.75 during the War has been removed. During three calendar years we sold Great Britain $5,956,000,000 worth of goods and imported only $733,000,000 worth, leaving a trade balance of $5,223,000,000. If sterling exchange had not been stabilized by purchases, through J. P. Morgan & Co., for the British government, it would have slumped long ago. Evidently the desire to restore normal conditions has prompted the step taken by the British government; also that of the French government, for the franc-dollar exchange likewise has been unpegged. The effect should be to curb imports into, and to stimulate exports from, Great Britain and France.

THE regular and early publication of an official statement dealing with the alloys and metallic minerals has long been desired by those engaged in mining. This need is now filled by the monthly excerpts from reports of the Minerals Investigation Committee of the U. S. Bureau of Mines, in charge of Mr. J. E. Spurr. Before us is the second number, that for February. Among the 43 pages the position of every metal and mineral of importance is discussed. In no way does this matter duplicate the valuable data published by the U. S. Geological Survey. Apart from a review of the production, imports, and exports of the principal base metals, those interested will find instructive information on antimony, chromite, graphite, magnesite, manganese, potash, pyrite, and zirconium. The market conditions for each metal or mineral are studied by officers of the Bureau detailed for this useful work.

THE 'Times' is not the paper it used to be, if it ever was quite the paper it was supposed to be, but it is still an authoritative exponent of British opinion; therefore we welcome the editorial statement made recently concerning the League of Nations and the international amity underlying any such agreement. The British people, says 'The Times', "without distinction of party, regards a better understanding with Americans as the crown of victory. . . . Our sole wish is to work with the American people in what we believe to be as much their ideals and interest as our own. Wishing that, with whom should we work but the President of the United States? That he is also leader of the Democratic party is a mere accident to our mind, and if the President had been a Republican we should have been at exactly the same pains to understand his point of view and work with him." That is frank and friendly. Undoubtedly Mr. Lloyd George is co-operating loyally with Mr. Wilson; the British premier is endeavoring, successfully, to reconcile the French and the American views on the war settlement.

WE are informed that the Chamber of Mines and Oil at Los Angeles has declined to support the Californian chapter of the American Mining Congress, preferring to work with the Oil Institute recently organized in this State. This we believe to be a mistake; it is merely a regrettable continuation of the lack of unified action marking the many elements in the mining industry. Obviously the various branches of mining acting separately cannot make such an effective presentation of a grievance or recommendation to those in authority at Washington as they could unitedly, through the agency established by the American Mining Congress. The oil industry of California has troubles that are peculiarly its own; they have become a subject of public controversy and they are less likely to be righted when treated as a matter that concerns a local industry than if they were treated as something injurious to the mining industry as a whole. Moreover, it is a blunder to assume, as is commonly done, that the winning of oil is not 'mining': of course, it is; the fact that the product is liquid does not place the exploitation of petroleum deposits outside the scope of an ancient art. Salt and sulphur are recovered in liquid form; in placer mining the gold is won through the medium of water. United we stand; divided we fall. If the different branches of mining refuse to co-operate in their approach to the departments at Washington, they are sure to fail in obtaining proper recognition.

GOLD production in Australia continued to decrease in 1918. The official statistics show a diminution of 12% as compared with 1917 and of 60% as compared with ten years ago. Every State of the Commonwealth, except New South Wales, shows a decline, but Victoria is the most unfortunate, the drop being equal to 25%.

	1908, oz.	1917, oz.	1918, oz.
Victoria	670,910	201,044	158,827
Queensland	465,085	175,280	130,123
Western Australia	1,647,911	970,314	876,508
New South Wales	224,792	82,171	87,045
South Australia	8,542	7,647	7,160
Tasmania	57,085	14,237	11,286
	3,071,325	1,450,693	1,276,949

The output of New Zealand can only be estimated—at 210,000 ounces as compared with 260,000 estimated in 1917 and 506,281 in 1908—because the annual report of the Department of Mines of that State omits the statistics of gold production, for a curious reason. The official explanation is that "the Imperial authorities are of the opinion that during the period of the War it is inadvisable to give exact information regarding the import and export of gold and silver." The Imperial authorities seem not to have laid such an embargo on other colonies and dominions under the British flag, therefore this action on the part of the New Zealand authorities is difficult to understand; it looks like an over-zealous attempt to comply with a suggestion from London, because it would seem as if the only information to be withheld, for patriotic reasons, would be the destination of the gold exported.

CHAIRMAN HURLEY of the Shipping Board is seeking expressions of opinion on the future maritime policy of the United States. It is to be hoped that he will not be disappointed. It is one of the most momentous economic questions before the people of this country, and should be discussed in every civic club and chamber of commerce from the Atlantic to the Pacific. For a hundred years we have done nothing but blunder in our national shipping policies. We have cluttered the statute-books with legislation to make the building and operation of an American merchant marine as nearly hopeless as we could. We have tried subsidies, limited so as to favor a few and prevent a national response to such stimulus. We have then cut off the subsidies and allowed splendid fleets to be sold at junk prices; our registry laws have discriminated against American ships; and without international negotiation for an agreement, which incidentally we never could have reached, we enacted a seaman's law that was useful to every competitor who wished to drive our flag off the seas. Reports indicate that some new principles have been adopted at Paris likely to equalize our maritime position in the world of commerce, but the details have not come forward. Mr. Hurley should issue a synopsis of our existing shipping laws, as a basis for general discussion, and then the public should seriously accept his invitation to offer comment. We have now a fleet of really large proportions. It belongs to the Government, and it must either be operated, allowed to rust and decay, or be sold. If it is employed as an American fleet it must be run by the Government, or the shipping laws must be intelligently revised so that private individuals may be able to operate it without running into bankruptcy. If our foreign trade is to be developed as an outlet for increasing products of the factory and the mine, it is important that an American merchant marine be sustained.

THE financial results of a company whose mines, smelters, and refineries recovered 2,496,693 ounces of gold, 69,841,061 ounces of silver, 916,974,000 pounds of copper, 550,532,000 pounds of lead, 52,500,000 pounds of spelter, 33,087 tons of sulphuric acid, and large quantities of many other metals and by-products during 1918, should be a good criterion of the condition of the metal markets. In this we refer to the American Smelting & Refining Company, whose report for the past year is before us. During that period, sales of metals realized $360,060,487, compared with $405,616,167 in 1917, and $330,297,952 in 1916. The value of the manufactured products was $14,006,145, $22,785,294, and $16,304,914, respectively. The profit for the three years was $14,137,168, $25,035,938, and $25,242,297. The total amount of dividends paid on both common and preferred shares during 1918 was 15% less than in 1917, itself a decrease of 2% from 1916. The company is carrying ore and products valued at $88,556,790, a trifle less than in 1917. Current assets total $35,530,676, and liabilities $30,654,731. Recently we referred to the retirement of the brothers Daniel, Murry, and S. R. Guggenheim from the directorate, after 18 years active participation in the company's varied operations. Since 1901, when these gentlemen became connected with the company, the annual turnover has increased from $82,000,000 to $390,000,000, and the profit and loss account from $2,900,000 to $27,000,000. The report, signed by Mr. Simon Guggenheim, states that the company has obtained no direct advantage from the increased value of the metals, and, on account of the complexities of the ore and metal markets, a conservative program must be maintained, so that dividends cannot be increased beyond 6%. The high costs of smelting and refining have been discouraging, but these items have lately been lowered; and although pre-war costs may never be realized again, the directors expect that pre-war profits per ton of ore smelted will be obtained as soon as normal business is resumed. Prospects in Mexico are considered to be encouraging. The smelters at Aguascalientes, Chihuahua, Matehuala, and Monterrey are in full blast, but Velardeña is not at work yet. The company is keen in its safety and welfare work, and reports a 28% reduction in the accident rate. The record is imposing, and we would like to be able to state that it synchronizes with an increase of public confidence in the methods employed by the 'smelter trust'. A business like this should have good-will in more senses than one. We would like to see the Senator, as Mr. Simon Guggenheim is still called by his friends, initiate a policy that would antagonize the ore-producers less and win public confidence more.

ACCORDING to Mr. S. R. Guggenheim, recently returned from Europe, it will be a long time before a large foreign outlet can be expected for American copper. Mr. D. C. Jackling stated at Salt Lake City recently that production costs are higher than the present market-price of the metal. To quote him, "There is no doubt whatever in my mind as to copper being stabilized, the same way as any other essential industry of the world. We are going through a hard winter in the copper industry. No one can say how long a hard winter will last, but there is an absolute certainty of spring; and, to carry out this simile, I believe we will have a bright and glowing summer." It was generally expected that at the conclusion of hostilities, Europe would need much metal of all kinds, but such is not the case as yet, for large stocks are lying in England, France, and Italy. These are a great factor in affecting the American markets, especially Great Britain, where, instead of stocks being consumed, they are actually increasing fast. For instance, the copper there on March 1 was nearly double the quantity at mid-December, lead was more than double, and spelter increased 40%; while aluminum, antimony, and nickel also had accumulated. To give an idea of normal supplies in England, we find that in 1913 those for copper totaled 11,500 tons, against 57,500 tons at present. A somewhat similar gain is shown by lead and spelter, of which there are respectively, 112,000 and 40,600 tons on hand. However, a few days ago Mr. C. F. Kelley of the Anaconda, on his return from Europe, stated that large accumulations of copper are in the hands of the Allied governments, but the copper-consuming industries are without stocks and the government supplies will be much reduced shortly by distribution among the consumers. Germany and her allies have no supply of copper and large quantities will be required when normal industrial activity is restored.

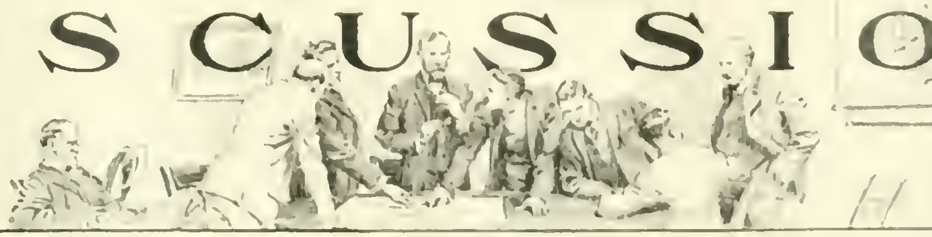
Bolshevism

Just a year ago we contrasted the conditions prevailing in Germany and Russia, under the heading 'Prussian or Bolshevist?' We said then: "On the one hand we see the concrete expression of highly organized and frankly autocratic militarism and on the other the disintegration of a nation plunging into the chaos of sentimental anarchy. To which of these extremes is the world drifting?" Twelve months have passed; the Germans did their best to distribute the propaganda of Bolshevism over eastern Europe before they themselves were beaten and held up their hands in abject surrender, but in their defeat they, like the Russians, succumbed to the poison of Bolshevism and fell into a riot of disorder, which in a few months has spread so fast over central Europe as to compel the Allies to face a further fight not with militarism, now cowed and dishonored, but with that foul fungus of anarchy which has sprung to life as if in a night upon the blood-soaked battlefields of Armageddon. What is this Bolshevism? The term Bolsheviki, now anglicized to Bolshevists, comes from the Russian word *bolsha*, meaning 'more'; they are the whole-hoggers; as is indicated more clearly by the synonym Maximalist, an abbreviation of Maximumalist. The Bolshevists are the party of the *bolshinstvo*, or majority. It is a gross mistake to speak of Bolshevism as "the extreme phase of Socialism," because these two ideas differ as much as black from white, as chaos from order. Bolshevism is distinctly anti-social; it aims to destroy the organization of society that has been laboriously, painfully, and even bloodily evolved by man since he emerged from an ape and tiger existence. The basic notion of Bolshevism is class-control by the proletariat, that is, the people without property. The Bolshevists aim at industrial, as well as political, monopoly; they extirpate all minorities; they deal more ruthlessly with those differing from them in opinion than any czar or kaiser; they are the foes of democracy and the enemies of liberalism; their scheme of disorderly living is an attempt to return to the savage childhood of the race; it is a reversion to the jungle. In this country they are represented by the I. W. W.; in Russia they used to be called Nihilists, and it is a pity that this term, with its evident meaning of unmitigated destructiveness in politics and morals, has not been retained. The use of the new name, Bolshevist, suggests that a new idea has been brought forth by the Russian revolution; it is nothing of the kind, it is only a fresh breaking forth of the savagery latent in man, particularly if he be uneducated. Of the Russians, 90% are illiterate. It appears that illiteracy is favorable to Bolshevism, as it is to other manifestations of human ignorance, but a second factor must be taken into account. General Mangin said recently, 'Bolshevism is essentially a disease of conquered countries." That is patent. Bolshevism feeds on defeat; it is the product of national disintegration. This is logical, for the Bolshevist has no national spirit; he aims to destroy national boundaries and to reduce the world to an international mob, seeking food like a herd of cattle. The capitalist and the organizer of industry are anathema to him, for he fails to see, or does not care to see, that without the organization of industry the peoples of the earth could not live, but would be the prey of famine and pestilence as in days gone-by, before human beings united to fight the hostile forces of nature. Without promise of security no man will grow more corn than he needs himself, for to accumulate a store of grain is to invite depredation; without the protection of the community no man will be tempted to increase his flock or herd, for that also would bring the marauder upon him; without railways and ships, without highly organized methods of transport and distribution, there would be no market for a surplus and no way of expediting that play of supply and demand on which the teeming millions now depend for satisfying the needs of their daily life. As to the effects of Bolshevism in Russia, we do not know much accurately, but we do know that a brigand, a thief, and a liar, Nicolai Lenin, rules the roost for the moment. Attempts, such as that of the Overman Committee of the Senate, to elicit trustworthy information have been largely a failure, because the witnesses, such as Messrs. David R. Francis and Raymond Robins, contradicted each other and themselves; but the picture is lurid enough, ranging from the murder of men wearing clean linen to the legalized rape of women. The menace of the outlaw is felt by civilization; the recent outbreak of the Bolshevist disease in defeated Hungary has awakened the Allies to the danger of postponing the settlement of peace; even Germany, once so proud of her highly organized statehood, threatens to turn Bolshevist if we treat her justly for her crimes, not the least of which is the fact that Bolshevism in Russia was fed on the lies that the Germans manufactured. The propagandists of kultur, the very people that insolently purposed to force their idea of administration upon the whole world, now threaten to turn anarchist if we are not kind to them; in November they were whining, now they are truculent: they are like the small boy who refuses to play unless you play his kind of game. The world faces a crisis as great as that of a year ago when the German armies broke the Allied battle-front. The sentimental idea of peace without victory has been translated by the brutal logic of events into a victory without peace. In truth, our leaders have failed us; not one of them, but all collectively. The Great War will go down in history as one in which no superlative leader of men was produced. We are suffering from the maladministration of governments and the lack of cohesion among the constructive forces of society. The War was marked by colossal blunders on both sides; the Armistice has been followed by wrangling and indecision among both the vanquished and the victors. If only one of the leaders in Paris had risen to the occasion and by force of genius had dominated the position, we should have emerged long ago from this darkness of divided counsels into the daylight of intelligent decision. If, for example, Admiral Kolchak with his gallant Czecho-Slovaks and Siberians had been supported not half-heartedly, as happened, but whole-heartedly and vigorously, the condition of Russia, and of eastern Europe as a whole, would have been vastly different from what it is now. Civilization is on a lee shore, in a fierce storm, and only a bold navigator can save the ship. Meanwhile it behooves the crew to be active and the passengers to behave themselves. Those that fail to meet the test had best be thrown overboard, which means that the cure for Bolshevism in the United States is deportation.

Mine-Sampling Again

We are glad to re-open the discussion on mine-sampling by means of a contribution that we published in our issue of last week and that came to us from Mr. H. R. Sleeman, who writes from a remote corner of Western Australia. He goes over some old ground, but in a useful way, since it is never amiss to state first principles before elaborating new ideas; for instance, the question of the cleanness of the sample and its relation to the actual mining that it anticipates. Our own, more than local, experience would lead us to lay stress on this point, for we believe that much of the failure of sampling to function as a prophecy is due to the fact that the sampling done by a moil and hammer yields a product much cleaner—therefore smaller in tonnage and richer in contents—than the ensuing stoping with machine-drills. This is due frequently, as Mr. Morton Webber says, to the 'sloughing' of waste from the walls or 'horses' in the lode. The post-mortems of mines prove this. Take the report of any good engineer made ten years ago on a successful mine and compare his forecast of tonnage and grade with the output of the mine since the date of his report; usually the record shows a lower grade and a bigger tonnage, because the manager's business was not to verify the report but to make as much money as he could for the stockholders, and that he could do, in most cases, by stoping wider than the sampling and by avoiding the expense of sorting afterward. Moreover, the lowering of the milling cost, consequent upon a bigger scale of operations or improvements in the metallurgical treatment, incites a continually increasing rate of production, because, again, the lowering of cost is a feather in the manager's cap, and both he and his directors are likely to care more for the credit accruing therefrom than to consider too severely the need for amortizing the cost of the mill-extensions out of current revenue. Indeed this phase of the sampling problem is fundamental. As we have insisted before, the process of sampling is determinedly non-selective, the aim is to obtain an average; whereas the aim of mining is to select the ore so as to make the maximum profit. That profit should be the maximum as a whole for the entire life of the mine, but often it is the maximum during a period of high metal-prices or the period during which a particular management, representing a particular group of stockholders, is in control. The Alaska Gold was, as the 'Boston News Bureau' said the other day, "an honest failure," and it was so because a group of clever engineers, with special experience in big-scale copper mining, failed to recognize the greater erraticism of free-gold ores, and because, more particularly, they assumed that a first-rate mine-captain like the late John R. Mitchell would extract average ore from the old Perseverance mine. Under his management 375,000 tons of ore had been milled, and this was deemed an *average* 'sample'. It was nothing of the kind, as was discovered when the big mill clamored for ore. This point should be emphasized again and again: mining necessarily is selective; sampling essentially is non-selective.

DISCUSSION



The League of Nations

The Editor:

Sir—In your editorial article of March 15 you sanely say: "Before this country is committed to so basic a departure from established policy * * * it is imperative that full information be given to the people." Further, you seem to imply that neither the President nor such leaders as Mr. Taft have been quite candid. You are right. We are confronted not merely by the problem of settling the War, but by a proposal to change our form of government fundamentally; more than that, to institute a new government to be composed of elements conflicting not only in tradition and instinct, but also in interest and purpose. There never was greater necessity for dispassionate consideration after full information and ample opportunity for discussion.

We are not now dispassionate; we are not yet informed; and the indications are we are not going to be given much opportunity for discussion. In view of what is involved in the constitution of a League of Nations I greatly fear that, in these circumstances, your instinct was right when you thought of a 'scrap of paper'; for, if the people do not understandingly and of the freest will accept the obligations imposed, there is grave danger that they may later repudiate the compact on the ground, valid to them, that there was no free meeting of minds.

I think we can all agree that there is no deeper degradation than that of a people who are not fully consulted as to the principle and plan of a new form of government to which they are to be subject. This is especially true when the Constitution under which they now live strictly limits the authority of their agent the President, and of their other agents the Senate. It seems to me that, at this moment of history, your article treats the American Constitution with too little gravity. It is no light thing when a people, even themselves, break with their traditions; when they cease to reverse the principles of conduct that have guided them along an orderly path of development; it is much more serious when their constituted authorities assume power to force the rupture.

The Romans had a concept of '*religio*' as the sum of the customs, traditions, and reverences that bind together in concord the otherwise discordant elements of society. In the sense that the Czardom was the '*religio*' of Russia, so is the Constitution the '*religio*' of America. Fortunately, the Constitution contains within itself the life-principle of growth. The President, the Senate, many of us, expressly, and all citizens implicitly, have taken the oath to defend the Constitution against enemies, foreign and internal. Let it not be thought that our Government is to be altered, or a new government instituted for us without orderly pursuit of the processes provided to that end. It is no longer a "group of men in the Senate;" it is no longer a question of Democrat or Republican, as already may be easily seen.

The chief danger to the United States lies, as always, in the hyphen—both the physical and the spiritual hyphen. Let us hope that the policy of America will not be determined by Irish-Americans, for whom strategical concessions are preparing; nor by German-Americans, who may be swayed by the already evident *rapprochement* of the governments, except France. Let us hope, too, that those who are spiritually French or spiritually British will not cease to remember that their first duty is to the United States. Above all let us not fail to "stand porter at the gate of thought" against the entry of ideas that are being sedulously propagated by the chancelleries of Europe for their own purposes, among the most insidious of which is the suggestion constantly reiterated that the League of Nations is an American concept against which France and Great Britain are struggling, but struggling in vain.

C. Irving Wright.

Pebble Beach, Del Monte, Cal., March 17.

Duluth Engineers Club

The Editor:

Sir—I note in your editorial entitled 'The Institute Meeting', in your issue of March 8, that you refer to the Duluth Engineers' Club as though it might be considered a rival and endeavoring to assume the characteristics of a national society. The inference may not be intended, but it can easily be taken. If you will allow me some of your valuable space, I will endeavor to state the ideals we are seeking to realize.

The Duluth Engineers' Club is distinctly a local organization and has no intention nor desire to be anything but local. It does, however, desire to co-operate effectively with all other engineering organizations in promoting radical improvement in the technical, political, and economic status of the entire profession. We believe that the desired co-operation can best be obtained by a federation of local clubs. The two basic principles upon which it must be founded are, first, direct responsible representation of the local clubs as such, and second, standard qualifications for membership in the local clubs.

We do not say this cannot be brought about through a re-organization of the present United Engineering Societies and the Engineering Council, but we do believe a thorough re-organization conforming to the basic principles before-mentioned will be necessary before a satisfactory solution of organization problems will be found.

Here in Minnesota, we have the Minnesota Joint Engineering Board, which is composed of a delegate from each local club. It meets about ten times a year and considers matters of interest to the engineer and concerning which the engineer is best qualified to speak. Its advice and assistance are frequently sought and used by the Governor and Legislature. Its activities are State-wide, but confined to Minnesota. This is just the kind of a body we need for national affairs.

A national body should be so constructed that it could take over all the functions of the existing national societies. It is possible they could be absorbed almost intact and made subordinate technical sections or bureaus. Briefly, the machinery of the federation would be a body of delegates, a small executive council, and a chief executive. The executive council would be elected by and be responsible to the body of delegates and would direct and be responsible for the chief executive.

The profession is paying, in dues alone, close to a million dollars a year for results that are pitifully inadequate. The older national societies have gone to seed along technical lines. The technical matter produced is inferior in quality and badly digested and poorly presented. There is limitless room for improvement right in the field they now try to fill.

The American Association of Engineers now proposes to take up the long-neglected social problems and work for the economic betterment of the profession. We are in hearty sympathy with many of its objects, but feel that its organization is wrong in the same particulars that the other national societies are. They are organized from the top down instead of from the bottom up. Their branches are 'appendages' instead of strong independent organizations which exist because of the local determination to be and do something of value in the community. The American Association of Engineers has placed the purely economic question so strongly to the fore that it faces the danger of becoming little more than a labor-union. If the ideals for which it was founded and which still guide its present officials could be maintained, there might be some hope of its ultimate success as a social and professional organization. We believe its chances are small to accomplish much due to its faulty organization and the personnel of the majority of its members. We believe every effort should be made to retain the high plane and professional prestige of the older national societies and add to it the vigor and enterprise of the local clubs and the American Association of Engineers.

There will be much prejudice, selfishness, and inertia to overcome, but the goal is well worth the struggle. The engineer claims to be particularly capable of designing, organizing, and managing enterprises. If he is to be judged by the manner in which he has handled his own professional affairs, he receives about all the consideration he deserves.

We believe a General Engineering Congress should be called of delegates from all engineering organizations, national societies, local clubs, and local 'appendages'. The four founder societies now have the committees studying problems of organization and these committees should be able to present some suitable plans that could be considered and a united organization formed that would include every man in America who is engaged in technical engineering or engineering administration.

We are talking, writing, and working for engineering unity, and invite every engineer to join with us in our struggle for a united profession.

W. H. Woodbury, Secretary,
Duluth Engineers' Club.

Duluth, March 14.

The Outlook for Copper

The Editor:

Sir—At the outbreak of the European war, it will be recalled, the copper mines reduced their production, and many of the large companies limited their output to 50% of the normal. This condition was induced by uncertainties contingent upon the European conflagration. There was at the time of this curtailment of copper production a need for the metal. It appears now, from a close analysis of the situation, that the uncertainties of what would be required by the new condition produced by the War, was instrumental in bringing about the curtailment. No one at the outbreak of the War appreciated what a great demand there would be for copper, and, if they did, they gave no evidence of confidence in their belief in such a demand. Many estimates have been made as to the amount of copper consumed for munitions, but exact figures have not yet been forthcoming. It is estimated from reliable sources that from 65 to 80% of the copper produced in this country went into the manufacture of munitions, up to the signing of the armistice. This left only 20 to 35% of the production available for domestic consumption. The normal consumption of the metal is about 1,300,000,000 lb., and for 1918 the production of the United States was 1,866,000,000 lb. In normal times the United States will consume about 73% of the copper coming from its own mines. From these figures it is evident that during the War the consumption of copper for the arts of peace was far below normal. During the period in which we were actively engaged in the European war there was great curtailment of the industries dependent upon copper. This curtailment in the manufacture of commodities needed in peace times has resulted in the depletion of stocks of copper goods. Likewise there was little extension of industry, the requirements of which in normal times would have increased the normal consumption of copper. In Europe there are only two countries which produce more copper than they consume, namely, Portugal and Spain. The production from Africa, Asia, and Australia does not increase, and they cannot be expected to furnish much toward the future demand, which is indicated. South America will add only a small quantity toward the total. It is evident that the United States will be called upon to furnish the major portion of the copper which will have to be mined to make up for the depleted stocks of copper manufactures. The Central Powers will require copper, and this will have to come from somewhere, and, even if it does not come from the United States directly, it is evident that this country will be called upon to make up the quantity consumed by them.

Should we graph the consumption of copper in this country over a period of 50 years, or even the last 15 years, it will be seen that it indicates a strong increase. This may be interrupted for a short time, but cannot be stopped because of the ever increasing industries that require the metal and are yet in their infancy. At the outbreak of the War many of the railroads were starting to electrify their lines. Inter-urban lines were greatly extended in the East as well as in the West. Water-power projects in the West were demanding greater quantities of copper every year. With the resumption of these projects there will be such a demand for copper as never before existed. There are large projects which contemplate the conversion of power at the mines in the East from coal to electric energy. This will require vast quantities of copper. The installation and extension of present electric transportation lines also will require large quantities. We are informed that buildings throughout the country are in great demand and that the general building program is far behind. This new construction will require no small amount of copper. In every industry we see depleted stocks and in every direction there appear new and large industries which require copper. The gravity of the situation, however, must not be underrated. During the days at the outbreak of the War in 1914 the copper market underwent a re-adjustment, born primarily of uncertainties. Despite the present surplus of copper now on hand, we find that for a long period the normal peace-demand for copper has not appeared. Not only will the lack of present stocks of finished copper products have to be replenished, but the onward march of new industries, with their ever greater demand for the metal, will have to be supplied.

Suppose we have in the United States 1,000,000,000 lb. of surplus copper on hand. The normal consumption is about 1,300,000,000 lb. for the United States. Of the two and a half billion pounds smelted in this country in 1918, approximately 75% has been converted into munitions or has gone into the destructive arts of war. This left 625,000,000 lb. for normal peace consumption. Therefore the constructive arts of peace have suffered to the extent of nearly 675,000,000 lb., which will eventually be made up. This will eat into the stocks on hand. The present condition is only temporary, and foresightedness under the present stringent conditions will place copper again to the fore. During the period of the War, copper production was increased at the expense of the most readily accessible ore-reserves. Development was either curtailed or kept at 'the irreducible minimum.' This has depleted the reserves of many of the large companies. To revert to a normal condition the development of ore-reserves will have to be pushed ahead of production. Advantage is being taken of this condition by some far-seeing mining companies who are at this time developing new properties and who intend to complete the development and equipment of their properties during the period while the market is unsettled. If the peace parley in Europe was finished the uncertainties would soon be removed, and with a clear vision ahead the copper industry would be advancing normally.

THEO. H. M. CRAMPTON.

Phoenix, Arizona, February 20.

Water Laws of Nevada

The Editor:

Sir—It is my understanding that the allotment of space to discussion in your publication is for the purpose of providing a forum for the discussion of current problems of general interest to the mining world—not an arena for the staging of personal controversies. It would appear that the discussion initiated some weeks ago by Mr. G. A. Duncan, regarding certain water litigation in the Eldorado Canyon district of southern Nevada is passing beyond the stage where it can be of interest or benefit to your readers.

The feature of general interest in Mr. Duncan's original contribution was his suggestion that the laws of Nevada, governing the disposition of surface-water, be applied to ground-water as well. In reply, I endeavored to point out the inherent difficulties of such an undertaking, and the danger to the mining community, already afflicted with an apex law, of further legislation of the same litigation-breeding species. The subsequent communications of Mr. Duncan and Mr. Brooks have been confined chiefly to a repetition of evidence introduced by them at the trial. To enter upon a refutation of their statements would be a further trespass upon the patience of your readers; but, in order not to let it appear, by default, that the complaint of Mr. Duncan is well founded, I desire to make a brief final statement in behalf of the mining company, which was the defendant of the water suit instituted by Mr. Duncan.

This defendant company, in accordance with laws and customs in effect since the inception of mining in the West, had been utilizing for milling purposes ground water, developed at its own expense by mining operations on its own claims. Mr. Duncan, by means of a freak water-right granted by the State Engineer, endeavored to appropriate this water. Had he been successful, it would have been possible for him, by carrying the matter to its logical conclusion, to have monopolized the entire water resources of Eldorado canyon, and by so doing to have compelled all the mines therein to close down or to pay him tribute. While the defendant company bore the brunt of the conflict, therefore, it had the material or moral support of practically all the other mining operators of the district. The trial of the case lasted a week; all the claims and contentions, which Mr. Duncan and Mr. Brooks have presented in their letters, were thoroughly threshed out; the defendant introduced abundant evidence in rebuttal; and the decision of the Court was to the effect that Mr. Duncan had failed to establish title to the water or to demonstrate that he had in any way been injured by the defendant company. That this decision was in accordance with the law and the evidence would appear to be sufficiently indicated by the significant fact that Mr. Duncan failed to appeal the case, as it was his privilege and duty to do if he believed otherwise.

Pioche, Nevada, March 8. R. T. Walker.

[This discussion is now closed.—Editor.]

The Immutable Law of Self-Interest

The Editor:

Sir—There are at least two natural laws which have come down through the ages without change. Neither has been altered by the ravages of war or the pursuits of peace. The first is the law of gravity and the second the law of self-interest. The correct solution of any problem in the field of physics demands conformance to the immutable law of gravity. And likewise if we desire to determine the correctness of the practicability of a political doctrine, or the feasibility of a proposal of finance, whether it be domestic or international, the same must conform to the immutable law of self-interest. Failing to satisfy this test it may be assumed that the political doctrine or financial proposal will either not win endorsement, or if enforced as an artificial measure will soon become inoperative because it has failed to take into account the law of self-interest.

Under the caption 'An Internationalized Gold Reserve', published in your issue of March 1, you have by very sound logical deduction branded the unique proposal of the Federal Reserve Board for the establishment of an international gold fund as being Utopian and financially unsound. It is my purpose to analyze the same proposal to determine whether it satisfies the law of self-interest. The more enlightened self-interest an individual may possess the better citizen he becomes, the more he will be able to contribute to civilization, the more he will realize the necessity of becoming self-sustaining, morally, politically, and economically, and the less of a burden he will be to the commonwealth in which he lives. So it is with the Nation. The more enlightened self-interest a nation may develop the better member of the family of nations it becomes, the more that nation will be able to contribute to civilization, the more that nation will realize the necessity of becoming self-sustaining morally, politically, and economically, and the less of a burden that nation will become to the rest of the world. It must be recognized now that the enlightened self-interest of the Allied peoples has just won a decisive victory over the ignorant self-interest of autocracy and has yet to win a victory over the people who have no enlightened self-interest—the Bolshevists. It will be seen that the enlightened individual self-interest, to which I refer, is the mainspring of good government, and finds its freest expression in a democracy.

When the gold reserve of the United States had began to accumulate rapidly, after the European securities had been finally liquidated against the trade-balance in our favor, many of the smaller nations, including neutrals, were forced to part with their gold reserve in order to live. The gold reserves of these smaller nations as well as the larger ones are now below the pre-war trade standard and will necessarily have to be augmented to satisfy the exacting conditions of trade. In the past when exchange began to run against any one of these nations it was a challenge to its pride to build up its gold reserve to a point which would maintain its credit standard in international trade on a parity with other nations. Enlightened self-interest became the assertive force and financial independence was restored. Who will say that this incentive of self-interest did not improve this nation and the world at large? Who will say that this proposal of amalgamated gold reserves in an international pool will not eliminate the incentive of self-interest by which national initiative and independence are sustained? The answers to these questions are self-evident. The proposal is not only chimerical, but practically untenable, as it does not satisfy the immutable law of self-interest.

H. N. Lawrie.

Portland, Oregon, March 10.

Explosives

The Editor:

Sir—In the excellent article on this subject by Mr. Robert S. Lewis, published in your issue of February 22, occurs the following: "Thawing should be done over steam-pipes at a temperature not above 122°F."

According to the best authorities, and also according to the rules of the Institute of Manufacturers of Explosives, this is not the proper way to thaw high explosives. Nitro-glycerine, an oil, loses its viscosity at high temperatures, and easily separates from the 'dope', or absorbent. Therefore, if cases of high explosives are stored over steam-pipes, and the dynamite should leak—which is not uncommon—nitro-glycerine might drop on the hot steam-pipes, causing an explosion. A drop of nitro-glycerine falling on a hot plate will explode.

Only exhaust-steam, hot air, or hot water should be used for thawing dynamite, and the radiator should be on one side of the thawing-house. The cases of high explosives should not be stored too near or *over* the radiator.

Mr. Lewis also states that a 60% low-freezing dynamite is not equal in strength to a 40% straight dynamite. This is not true of low-freezing 60% dynamite manufactured by the DuPont company. DuPont 60% Red Cross Dynamite (low freezing) and DuPont 60% Straight Dynamite are exactly of the same strength, both having a Triton value of 11, that is, 10 grammes of each of these dynamites is equivalent to 11 grammes of T.N.T. in the ballistic mortar.

Price-Levels and Readjustment

By RICHARD HOADLEY TINGLEY

The problems of post-war readjustment are proving more perplexing to the American business man than were those involved in adapting himself to war conditions four years ago. The War has been over several months, and business hasn't yet been able to figure out how to readjust itself. On the other hand, business had practically 'found itself' by December 1914. It had made up its mind, by that time, what war meant, and had its plans ready to meet it.

Business is still 'sitting tight' and waiting. It cannot make up its mind whether it is going to be good or bad; whether prices are going to advance or decline. This is the crux of the matter. As soon as business makes up its mind that commodity prices have reached a reasonably stable level, be it high or low, conditions cannot fail to improve.

There are two opposing theories regarding prices of the future. Let us examine them both.

Those who anticipate a radical decline in the near future base their conclusions on the fact that there is, and will be, a continuing volume of labor released from munition plants to resume the production of the goods of peace; that steel, copper, coal, shipping, and other essentials are being released from war needs again to contribute to the demands of peaceful pursuits; that millions of soldiers are returning to the farms, the factories, and other peaceful occupations, and that, in consequence, there will be an immense increase in the volume of goods available for civilian consumption. This condition, they say, should make for low price-levels and restricted business.

Those who entertain the opposite view maintain that war has produced a shortage in nearly all the essentials used by a civilian population. They maintain that almost every available factory that produces essentials has had a considerable proportion of its capacity engaged for the past few years in the manufacture of war goods of one kind or another, and that, in consequence, the stock of such goods available for civilian consumption has been reduced so far below normal that it will take a year, at least, to catch up with the demand. They cite the case of that prime essential to our bodily comfort, the cotton goods supply. During the year and a half in which this country was engaged in war the productive capacity of the factories of the cotton spinners has been engaged, on an average, about 60% on civilian goods and 40% on war supplies. The sudden disruption of plant organization has so reduced the efficiency of these plants that an output of hardly more than 80% of the 60% has been reached. It would appear, then, that in the manufacture of civilian goods, only about 50% of the normal use and demand has been produced during this period. A large proportion of this reduction in supply may now be called a shortage: a shortage of all kinds of cotton goods that amounts to upward of seven billion square yards of cloth! This shortage must, in part at least, be made up. We can deny ourselves these essentials for awhile and reasons of patriotism as well as of economy have influenced us in keeping down our purchases not absolutely needed. There comes a time, however, when we must 'stock up'. This time will come when we make up our minds that prices have sufficiently receded from war-levels and have reached something like a stable basis. Be that stable price high or low we will then be in the market for the purchase of those things that, for one reason or another, we have been doing without.

Much the same argument may be applied to the manufacture of almost every essential product and the effect, to my mind, is going to keep prices from a drastic drop till we have finished our operation of 'stocking up'.

Unless all previously accepted laws governing price-movements are to be violated there can be no drastic drop in commodity prices for some time to come, at least, no drop to anything like pre-war levels. We are taught that the presence of gold in abnormal quantities is sure to stimulate credits and that stimulated credits is sure to inflate prices. We are taught, too, that an inflated currency will surely make for high price-levels, and that high price-levels and good business always go hand in hand. Which is cause and which effect it is unnecessary to discuss here.

The exigencies of war have brought an abnormal supply of gold to our shores. More than a third of the stock of the gold of the world is at present in this country. Two-thirds of this is in the hands of the Federal Reserve banks. Our currency has been inflated from $34.56 per capita before the War, to approximately $55 at the present time, and we have had an unprecedented era of high prices. It would not be safe to argue that these abnormal monetary and credit conditions are solely responsible for the inflated prices we have had and that are still with us. The disrupting influences of war and the diversion of labor and capital from peaceful pursuits to those of destruction are, no doubt, more potent influences making for high price-levels than the monetary influences. The fact remains, however, that high prices are a sure accompanyment of an inflated currency and an abnormal supply of gold.

But what of the future? There is no indication that our stock of gold is likely to be reduced in the near future, nor the currency issue cut down. With an export business that is sure to be in excess of our imports; with interest money payments from European countries on our war loans to them coming in; with freight-charges accruing from earnings of our newly acquired merchant marine, there will be no compelling demand for our gold to leave us for other countries. On the other hand, more gold will be due us from abroad unless we adopt the broad policy of investing our surplus moneys due us from other nations in fostering their home industries.

All these conditions will continue to make, according to the theories of the economists, for high price-levels in this country till the conditions have changed. Will this theory be vindicated? Or, has the world-war created such different economic conditions that it will be upset and violated? Despite the fact of our abnormal gold and our inflated currency will prices drastically decline?

Let me quote another parallel from Dr. E. E. Pratt, Chief of the Bureau of Foreign and Domestic Commerce at Washington, on the effect of past wars on prices. He says that, taking the average prices in 1860 as 100, the index numbers show that during the eight years preceding the Crimean war, prices in England averaged 85, and during the ten years following this war they averaged 121.6 on a gold basis. Again, in Russia, prices averaged 102.8 during the period of ten years before the Russo-Japanese war, and 129.8 during the seven years following that war. In Japan the prices of food, clothing, and materials averaged 98.8 during the four years preceding, and 122.1 during the seven years following the war. Dr. Pratt concludes that Europe is now entering upon a period of high prices and thinks that this condition will continue for ten years or more. If this is true of Europe, much the same conditions may be expected in the United States.

In the light of all of the above the American business man must draw his own conclusions. It is the wise man, however, that correctly forecasts the business future. It was the wise man who, in 1914, realized what a state of war would mean to him in his business. It is the wise man who can see, a little in advance of others, what the readjustment of peace is going to mean to him, and, in the light of the evidence, there seems to be but one conclusion.

Ventilation and Fire Protection in the United Verde Extension Mine

By CHARLES A. MITKE

*Ventilation. There are three shafts at the U. V. X.—the Little Daisy, Edith, and Andrey—and two raises to the surface, one for ventilation, the other for waste. The Andrey, when completed, will be the main hoisting shaft, the Edith, the supply shaft, while the Little Daisy is used entirely for ventilation. One suction-fan, having an air capacity of 40,000 cu. ft. per min. is placed at the top of the Little Daisy shaft; and another, of 135,000 cu. ft., will be erected at the top of the air-raise, which will become the main air-shaft. A connection will be made from the long tunnel directly to the large orebody on the 1300-ft. level. A raise will be driven from the 1400-ft. level, connecting at this point, so as to force all the fresh air entering the large tunnel down to the lower workings. Doors have been put in at the different shaft-stations on the 800, 1100, and 1200-ft. levels, in order to force all the air to pass through the different stopes.

Arrangements will be made for the proper coursing of the air through the Bonanza orebody, where it is most needed. Gangways, immediately beneath the capping and connecting old raises, have been preserved by building walls of waste-rock. These are maintained solely for ventilation purposes and will remain open for some time in order to afford a means of escape for the heated air from the old square-set sections.

While at present the temperature, humidity, and velocity of the air in the different working-places fall somewhat below the requirements for a good working atmosphere, when the necessary development work is completed, standard raises built, and the large mine-fan completed on the surface, the volume of air passing through the workings will amount to at least 400 cu. ft. of air per man per minute and the United Verde Extension will be one of the best ventilated mines in the South-West.

Fire Protection. A spraying-system has been fitted in the Edith shaft. In case of fire in this shaft, the fire-doors on the 1300 and 1400-ft. stations will be closed immediately by means of compressed air and the sprays, which are controlled from surface, put into operation. The doors on the 800, 1100, and 1200-ft. levels are ventilating-doors, and are always kept closed. The mine-fans would also be stopped at once, but not under any other circumstances.

The Little Daisy shaft, which is used entirely for ventilation, has a concrete connection from the fan to a depth of one set below the collar. From there down it is naturally so wet as to make a fire-protection system unnecessary. The new Andrey shaft is fire-proofed by its being concreted. The barriers of waste left by the Mitchell stoping method will serve as fire-breaks in that part of the Bonanza orebody in which this system is used.

A number of electric-blowers, and a sufficient supply of bulkheading material and fire-fighting equipment, are kept on hand so that the fire-area can immediately be put under pressure and steps taken to extinguish the fire. Should these measures fail, the general procedure will then be similar to that followed in mining out the fire-area in the small orebody, from which, for 1½ years, ore that was actually on fire was mined successfully under pressure without interfering with the production or the daily mining operations of the remainder of the mine. During this time not a single serious injury was reported.

Platinum production of Canada during 1918 totaled 39 crude ounces, a decrease of 18 ounces. This was all saved from placer mining in the Similkameen district of British Columbia.

Chromite imports in January were 12,263 tons, valued at $486,404; against 6858 tons and $318,293 in December. Neither New Caledonia nor Rhodesia are on the list yet.

---

*Abstract from Bulletin 147 of American Institute of Mining Engineers, February 1919.

The Yerington District, Nevada

By ADOLPH KNOPF

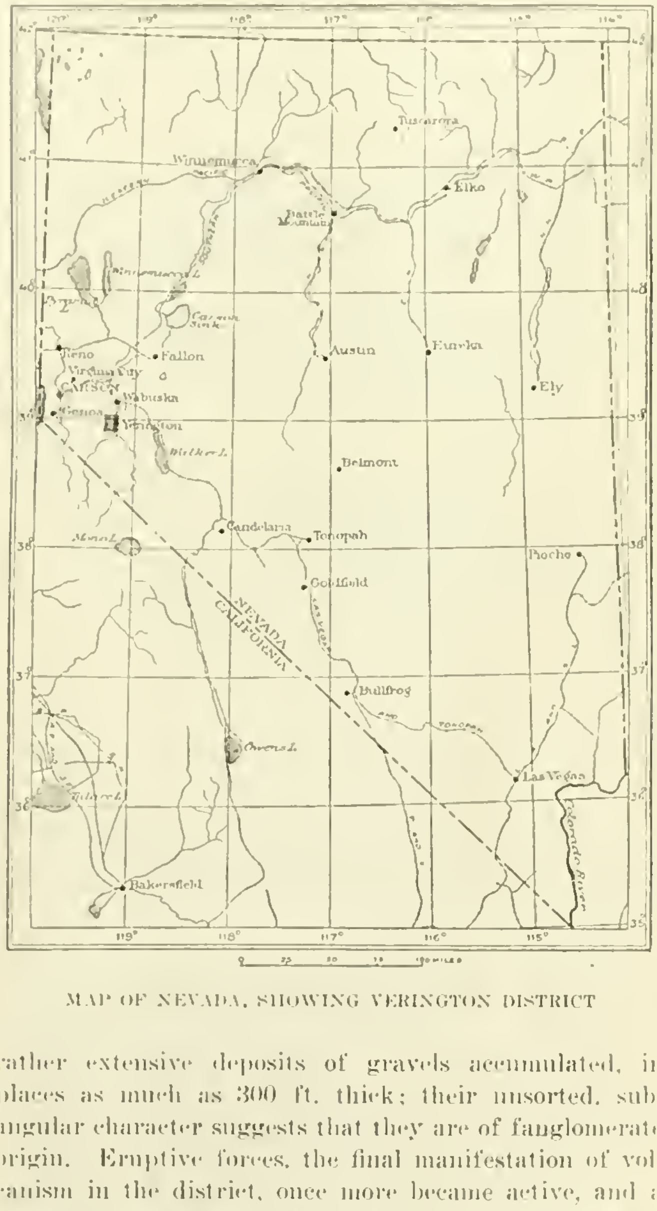
*The oldest geologic records of the district date back to the Triassic period. At this time 4000 ft. of andesitic and dacitic lavas, breccias, and tuffs were erupted, which were succeeded by a peculiar series of soda-rich felsite lavas and tuffs. Marine conditions then prevailed, and limestones mainly were laid down, interrupted, however, by occasional eruptions of felsite. At one time during the Triassic a bed of gypsum, as much as 450 ft. thick, was deposited.

These rocks were folded, probably in the beginning of Cretaceous time, and were intruded, probably early in the Cretaceous, by large masses of grano-diorite and quartz-monzonite. These intrusions were followed by others that brought in minor amounts of aplite and considerable amounts of quartz-monzonite porphyry. Faulting occurred during and immediately after this epoch of intrusion, and as a sequel to the intrusive activity the ore-bodies were formed.

A long period of erosion then ensued, during which the Triassic rocks were in places entirely removed and the granitic rocks were laid bare over wide areas. Volcanic eruptions followed, probably in the later part of the Miocene, and buried the fluvial deposits that had accumulated on the surface eroded upon the older rocks. The relief of this surface on which the Tertiary rocks accumulated appears to have been moderate, though on account of the small exposures and the profound faulting to which the rocks of the region have been subjected this conclusion is not firmly established. At any rate, the streams that flowed on this surface appear to have been powerful, as is indicated by the well-rounded boulders, six feet in diameter, occurring in their gravels.

The volcanic activity began with the effusion of a distinctive flow of black glass, a latite vitrophyre; this flow was succeeded by quartz-latites, which are especially characterized by their columnar structure; and upon these were piled about 4000 ft. of rhyolites and 1400 ft. of andesite-breccia. From time to time during the general period of eruptive activity fluvial and lacustral conditions prevailed; the most noteworthy of these interruptions led to the deposition of 430 ft. of lake-beds, which occur at the top of the rhyolites and underlie the andesite-breccia. This succession of rocks, beginning with the vitrophyre at the base of the section and including the andesite-breccia at the top, appears to correspond to the Esmeralda formation, which is now believed to be of late Miocene age.

After the deposition of these rocks a period of pronounced diastrophism set in, the most vigorous in this part of Nevada during Tertiary time. The rhyolites were tilted at angles of 25° to 65° and were greatly faulted, the rocks being displaced stratigraphically to the extent of thousands of feet. Erosion ensued, and subsequently andesites were erupted, now resting at low angles upon the worn edges of the rhyolites. This eruptive outburst was extremely moderate and is represented by only a few hundred feet of lava.



MAP OF NEVADA, SHOWING YERINGTON DISTRICT

After the andesitic extrusion erosion again began, rather extensive deposits of gravels accumulated, in places as much as 300 ft. thick; their unsorted, subangular character suggests that they are of fanglomerate origin. Eruptive forces, the final manifestation of volcanism in the district, once more became active, and a series of basalt flows was poured out. The basalts, although nearly horizontal, have been considerably faulted, and this period of vigorous diastrophism is held to mark the beginning of Quaternary time. The faulting that took place at that time blocked out the Singatse range largely as we see it now. Since this faulting the deep

---

*Abstracted from Professional Paper 114 of the U. S. Geological Survey.

canyons opening out upon Mason valley have been excavated, and the material thus derived has built up a series of alluvial cones fronting the range.

The main orebodies of the Yerington district are copper-bearing deposits characterized by a gangue of either pyroxene, garnet, or epidote, or a mixture of these minerals. Chalcopyrite is the chief copper-bearing mineral; pyrite is commonly associated with it, but no other primary sulphides occur in the district.

The deposits belong to the contact-metamorphic group. The primary ore is essentially unenriched by later sulphides, for supergene covellite and chalcocite, although occurring locally, are as a rule not abundant.

Orebodies of this kind have yielded the bulk of the metal output. The average tenor of the ore mined has ranged from 2.75 to 6% of copper, with gold and silver present in traces only. Among the representatives of this group are the orebodies of the Bluestone, Mason Valley, Ludwig, Douglas Hill, Casting Copper, and McConnell mines.

Other types of the copper deposits are sparingly represented in the district and as a whole are of minor economic importance. They are exemplified by the irregular bodies of rich cuprite ore in quartz-monzonite porphyry at the Empire-Nevada mine and by the fissure-veins in quartz-monzonite and quartz-monzonite porphyry.

The principal copper deposits of the district, characterized by their pyroxene, garnet, or epidote gangue, have, with one notable exception, been formed by the replacement of limestones. The Bluestone orebody, the exception alluded to, consists essentially of chalcopyrite in an epidote gangue and was produced by the replacement of brecciated garnetite and allied silicate rocks.

The limestone beds in which the orebodies developed are shown in the following paragraphs to have been relatively pure calcite-rocks. Their chemical composition is a matter of some theoretical interest. Lindgren and others have presented evidence to show that orebodies of this type have commonly formed in limestones of extreme purity. Leith and Mead,[†] however, consider the evidence thus adduced to be doubtful and inadequate, inasmuch as the specimens chosen for analysis represented only single strata, and they emphasize the fact that to obtain evidence of conclusive value samples must be taken across the full width of the ore-zones.

Analyses of the limestone in the ore-bearing zone of the Mason Valley mine of the Yerington district are available that in large measure meet Leith's requirement. The limestone was used as smelter flux and hence was carfully analyzed for lime and silica but less carefully for other constituents. A glory-hole 200 ft. long, 60 ft. wide, and 75 ft. deep was opened up. The limestone is mainly in beds ranging from 5 to 10 ft. in thickness but includes some thinly banded varieties. The beds strike north and dip 70° or more westward; the longer axis of the glory-hole is parallel to the strike of the strata. In column 1 of the subjoined table is given an average of seven analyses of limestone from the stope, and in column 2 an average of four analyses of limestone from the 'new stope' situated in the immediate hanging-wall country rock of the ore-bearing zone; from this stope limestone flux is now being obtained. The individual analyses do not vary widely from the average figures.

Analyses of Limestone From Mason Valley Mine

	1	2
CaO	46.9	48.5
MgO	2.3	0.6
SiO_2	9.1	5.7
Al_2O_3	4.0	2.2
Fe_2O_3	1.1	2.3
CO_2 (theoretic)	39.4	38.7
	102.8	98.0

In these analyses, according to the smelter manager, the lime and silica were carefully determined, as these are the constituents of importance in calculating the furnace charge, and the determinations of the other oxides are of nominal value only. The defective summations of the analyses are doubtless due to this imperfect determination of the minor constituents.

The analyses concur in showing that the limestones of the ore-bearing zone and of the hanging wall are relatively pure; they are slightly silicous but are low in magnesia, alumina, and iron.

Two specimens of limestone obtained from the south end of the ore-zone on the No. 3 level of the Mason Valley mine were analyzed in the laboratory of the U. S. Geological Survey. The great ore-lens on the south end of this level extends obliquely across strata of limestone of different colors, ranging from light bluish-white to dark-gray or black. These beds carry a few fibres of tremolite and sporadic cubes of pyrite. The limestone represented by column 1 of the subjoined table, taken 20 ft. from the edge of the orebody, is a dark-gray, almost black, crystalline limestone; under the microscope it proves to consist preponderantly of calcite grains, with accessory tremolite and pyrite. The limestone represented by column 2, taken from rock immediately adjoining the solid andradite of the periphery of the orebody, is a light-gray, rather dense, limestone; under the microscope it proves to consist essentially of calcite and a few scattered fibres of tremolite.

Analyses of Limestone From Mason Valley Mine
[W. C. Wheeler, analyst]

	1	2
CaO	52.12	51.63
MgO	0.84	3.17
SiO_2	3.04	1.80
Al_2O_3	1.39	0.14
Fe_2O_3 (total)	0.64	0.17
CO_2 (theoretic)	41.87	41.02
	99.90	100.93

These analyses show that the two specimens selected are somewhat purer than the average as found by the smelter determinations. The analyses are of the same general purport, however, and confirm the statements made as to the essentially non-magnesian character of the limestone of the ore-bearing zone and their low content of silica, alumina, and iron.

The orebodies at the other mines in the district have formed in coarse calcite-rocks, which without doubt are of the same general character as the limestones analyzed

---

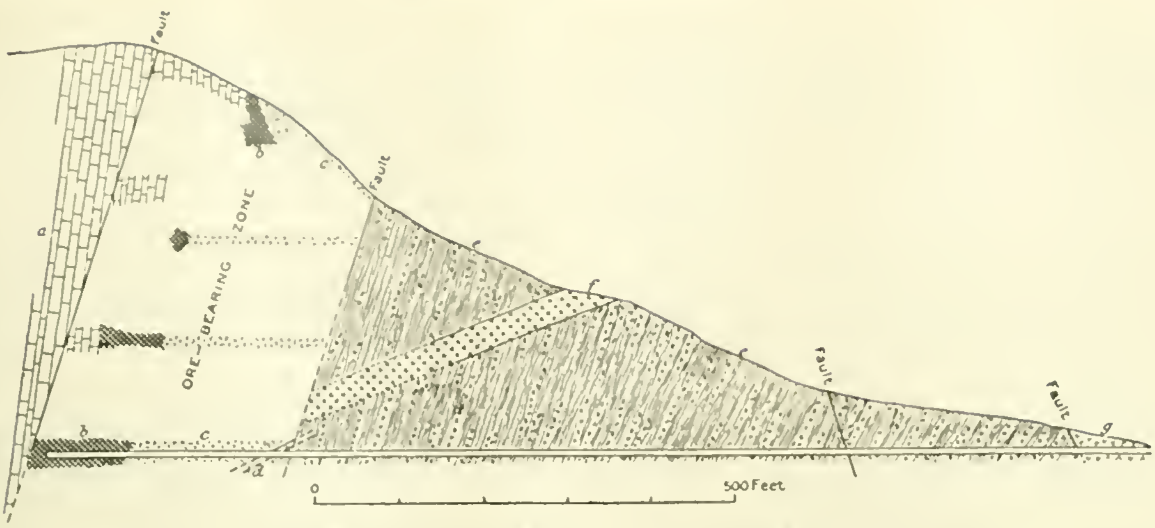

FIG. 2. SECTION THROUGH TUNNEL NO. 4 OF THE MASON VALLEY MINE

a. limestone; b. ore; c garnetiferous rock; d. basic dikes; e. lime-silicate rocks with intercalated felsites; f. quartz monzonite porphyry; g. Tertiary rhyolite

The ore deposits are situated on or near fault-contacts. Commonly the faults separate dissimilar rocks, such as limestone from felsite, andesite, or stratified calc-silicate rocks. That the faulting occurred before the orebodies were formed is established by the following structural relations: (1) The faults displace the quartz-monzonite porphyry dikes, and the severed ends of the dikes and the fault drag from the dikes have been metamorphosed by the ore-forming solutions; the brecciated quartz-monzonite porphyry at the Bluestone orebody, which is an epidote-chalcopyrite deposit, is profoundly epidotized and pyritized; and the porphyry enclosed in the Ludwig lode is garnetized, silicified, and pyritized. (2) The calc-silicate rocks, such as the fine-grained grossularite rocks near the Douglas Hill mine, have been brecciated, and the shattered mass has been re-cemented by the coarsely granular andradite that was formed at the time the ore was deposited; at the Casting Copper mine a series of thin-bedded black garnetites and allied rocks abut at an angle of 45° upon a belt of crystalline limestone, the garnetites were broken along the contact, and the angular black fragments are enclosed in the yellow andradite that forms the gangue of the orebody. These significant structural relations, pointing to the considerable faulting that intervened between the time of intrusion of the quartz-monzonite and the deposition of the ores and proving the dependence of ore deposition on fissuring, will now be considered in some detail.

The relation of the ore deposits to faulting and brecciation is shown most strikingly at the Douglas Hill and Casting Copper mines; nor is elsewhere shown so clearly the distinctness of the ore-forming mineralization as a separate event that took place after the metamorphism accompanying the intrusion of the quartz monzonite. The mineralogically complex series of calc-silicate rocks on the west flank of Douglas Hill has been described; toward the top of the hill these rocks consist of exceedingly dense fine-grained garnetites, composed almost wholly of a nearly pure grossularite, as shown by its index of 1.75. The summit of the hill consists of an immense mass of andradite in which the ore occurs as irregular lenses. This great body of andradite resulted from the replacement of a massive limestone lying above the stratified series of aphanitic garnetites. The foot-wall of the ore-zone is a belt of remarkable breccia about 20 ft. thick. This breccia is composed of sharply angular fragments of the aphanitic garnetites enclosed in a cementing matrix of coarse euhedral yellow garnet. The index of this garnet proves to be 1.87 and determines the garnet to be a nearly pure andradite. The garnets of the two periods of metamorphism show, then, in this grossularite hornfels cemented by andradite their maximal possible contrast. The andradite cement carries a little interstitial quartz, apatite, and chalcopyrite.

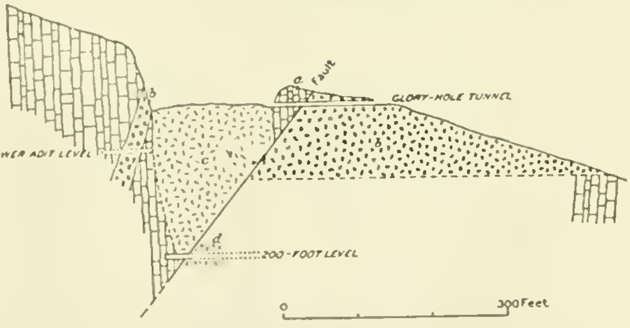

FIG. 1. SECTION THROUGH THE GLORY-HOLE TUNNEL OF THE McCONNELL MINE

a. limestone; b. basalt; c. garnet-rock and ore; d. Triassic andesite

The dependence of ore deposition on fissuring and the evidence of two distinct periods of garnetization are clearly shown at the Casting Copper mine. The ore-bearing zone lies along the fault-contact of a stratified series of black garnetites striking at an angle of 45° against massive limestone. The garnetites are dense, heavy, fine-grained rocks. Under the microscope they are seen to be composed wholly of garnet, which is clouded with carbonaceous inclusions, a feature that accounts for their black color. The massive limestone has been solidly replaced by coarsely granular resin-yellow andradite for over 400 ft. along its contact with the stratified garnetites. The garnetites were shattered along the contact, and the angular fragments of dense black rocks that resulted therefrom are now outlined by the thin veinlets of euhedral yellow andradite that traverse the breccia.

Some of the ore deposits, as the Bluestone, Mason Valley, and Western Nevada, are situated at the contact of the Triassic rocks with the quartz-monzonite or the grano-diorite. This contact, however, proves to be faulted; in fact, the grano-diorite at the Mason Valley mine is a narrow fault-wedge lying between the ore-zone and Tertiary rhyolites to the north. The time of the faulting, except that it is later than the intrusion of the quartz-monzonite porphyry dikes, is unknown, as is also the amount of displacement. The other garnetiferous ore deposits of the district are at some distance from the large intrusive bodies; that farthest distant—the Douglas Hill, which is characterized by its extraordinarily extensive mass of andradite—is 2500 ft. from the nearest surface exposure of quartz-monzonite.

The limestones adjoining the faults along which the ore-forming solutions rose were shattered, and there is some evidence that the shattering facilitated or governed the replacement of the limestone by the mineralizing solutions. In the Ludwig orebody, which is lode-like in form, the limestone was extremely broken and crushed by dynamic disturbance, forming breccias as much as 80 to 100 ft. thick. The garnetiferous quartz-pyrite ore, carrying coarse calcite as a minor component, forms a large low-grade shoot 50 to 100 ft. wide. Toward the foot-wall side of the orebody, where it grades into unreplaced limestone and where the mineralizing activity was presumably less intense, the result of the selective action of the solutions becomes apparent. Here the finely crushed limestone that formed the matrix of the larger angular fragments of the breccia was replaced by pyrite, and thus a limestone-breccia cemented by pyrite resulted. In the same way the brecciated condition of the quartz-monzonite porphyry occurring in the Bluestone orebody has been strikingly emphasized by the selective replacement of the more finely crushed portion of the breccia. It was further emphasized by the fact that the sulphides form margins around the larger fragments of the breccia.

The replacement of fractured and brecciated limestone by andradite and sulphides is recognizable along the periphery of the large ore-lens at the south end of the ore-zone of the Mason Valley mine. The andradite and sulphides have replaced a dark-gray fine-grained limestone; the junction between wholly replaced and unreplaced limestone is sharp; and the only change shown by the limestone is that where it adjoins the replaced rock it is bordered by a white band less than half an inch wide. The limestone has evidently been decarbonized in this band, but its grain has not been coarsened. At the McConnel mine, also, there is some evidence that the replacement by the mineralizing solutions progressed along fractures. See Fig. 1. However, it is difficult to obtain proof in many of the deposits in this district, as in others, that replacement by garnet, pyroxene, and allied silicates was governed by the fractured condition of the limestone in which they have developed. The conclusion to be drawn from this general lack of positive evidence is probably that the replacement of limestone by garnet and allied silicates is commonly so thorough that it has obliterated the evidence of the pre-mineral fracturing. There has consequently been a general tendency to regard ore deposits of this kind as having originated at high temperatures and pressures from solutions permeating the limestone by diffusion or through microscopic fractures.

From the preceding discussion it appears that the chief ore deposits were localized by the ascent of the ore-forming solutions along fault-fissures. The presence of limestone obviously appears to have favorably influenced the precipitation of ore. The main orebodies are in the limestone adjoining the faults, but concomitantly with the deposition of the ore large bodies of garnet and pyroxene were formed, which in amount greatly exceed the ore. To find the bodies of ore in this unprofitable envelope is one of the main problems of mining in the district. As a rule, not without important exceptions, however, the ore tends to occur in the marginal portion of the contact-silicate rock where this borders the limestone. This tendency shows most clearly in the orebodies of the Mason Valley (Fig. 2) and Casting Copper mines. That ore is most likely to occur on the limestone side of the contact-metamorphic copper deposits at Mackay, Idaho, has been recognized by Umpleby;[2] and in a later paper by the same writer[3] this rule is shown to apply to a considerable number of other contact-metamorphic deposits. The Yerington district broadly supports the rule.

Operating Data of the A. S. & R. Co.

The report of this company for 1918 gives the following summary:

	1917	1918
Number of men employed; excluding Mexico	24,698	21,765
Total wages and salaries, excluding Mexico	$24,497,836	$25,516,467
Average wages per 8-hour day	$3.31	$3.91
Charge smelted, tons	5,918,924	5,658,232
Bullion refined, tons	706,875	680,099
Coal used, tons	787,890	765,124
Coke used, tons	592,765	545,063
Fuel-oil used, barrels	1,560,535	1,659,337
Gas used, cubic feet	3,032,908,373	2,372,000,103
Ore mined, tons	2,318,925	2,525,280
Coal mined, tons	259,499	168,140
Coke produced, tons	186,107	171,245
Metal products:		
Gold, ounces	2,496,693	1,994,015
Silver, ounces	68,841,061	72,572,506
Platinum and palladium, ounces	1,597	1,516
Lead, tons	275,266	260,192
Copper, pounds	916,974,000	868,540,000
Spelter, pounds	52,522,000	41,238,000
Nickel, pounds	682,715	626,085
Tin, pounds (from Bolivian ore)	12,130,000	19,868,000
Sulphuric acid, tons	33,087	43,669
Arsenic, pounds	9,132,000	7,837,063
Copper sulphate, pounds	7,598,000	5,164,000
By-product metals, pounds	4,131,709	1,870,662

Technical Writing: The Construction of Sentences

By T. A. RICKARD

*In order to write clearly—that is, so as to be understood beyond question—you should know not only what your words denote but how to build your sentences: you must not only choose your words carefully but you should construct your sentences properly. To achieve proper construction, you must obey the laws of syntax, because the meaning of clauses and sentences depends upon the order of words. A sentence is a combination of words that expresses thought: it says something about something. A clause is a subordinate sentence; it is part of a larger sentence. The Greeks call an editor a *συντακτης* (suntaktes), he who assembles the parts of a sentence. Hence our word 'syntax' for the branch of grammar that treats of the sentence and its construction. English is essentially a non-inflected language; and in that respect it is unlike not only Latin and Greek but its modern rivals, French and German. This lack of inflections, to indicate the relation of words, makes it supremely necessary that in English our words shall be placed in correct order, for we depend upon the order to indicate the sequence of thought. Any deviation from the logical sequence may endanger the meaning; for example:

When spies were feared in England at the beginning of the War, a local paper stated:

(1) "The authorities are now looking for a gray motor-car driven by a woman who is thought to have a wireless apparatus inside."

A technical journal announced:

(2) "We publish an article on errors latent in the sampling of mines by Mr. Blank." The mention of the author should have followed 'article'.

(3) "He blew out his brains after bidding his wife good-bye with a shotgun."

(4) "Mrs. Smith was killed on Wednesday morning while cooking her husband's breakfast in a shocking manner."

(5) "The owner of this property fishes and shoots himself."

(6) "The concentrating table was covered by the foreman with a new face of rubber."

(7) "The samples were preserved for analysis in a paraffin-sealed flask."

(8) "Care should be taken to see whether such wells are contaminated by frequent analyses.

The foregoing examples of incoherence break the rule that "the relation of each word and each clause to the context should be unmistakable." Another rule says "Clauses that are grammatically connected should be kept as close together as possible." As a further warning I quote the following:

(9) "The expedition, which left Fairbanks March 13, expected to reach the summit of Mt. McKinley early in May, but was delayed three weeks cutting a passage three miles long through ice with hand-axes thrown across the ridge by an earthquake last summer."

That must have been a weird earthquake! it threw hand-axes across a ridge! Even if you place "with hand-axes" after "passage" you find yourself saying that the hand-axes were "three miles long." Note the slovenliness of style: the omission of 'on' before "March 13," of 'while' before "cutting," and of 'it' before "was delayed." The statement can be amended thus:

"The expedition . . . was delayed three weeks by having to cut with hand-axes a passage three miles long through ice, which had fallen across a ridge in consequence of an earthquake last summer."

Place clauses in their logical order; the inversion of ideas is confusing.

(10) "Combined with geological ability of an unusual degree, he was an all-around engineer."

No sensible man talks in this way; the phrasing is stilted and obscure. It is better to say:

"He was not only an all-around engineer, but also an excellent geologist."

(11) "Due to the richness of the new orebody on the tenth level, the mine has paid dividends." He means that:

"The mine has been able to pay dividends, thanks to the richness of the new orebody on the tenth level."

(12) "Compared with what I had seen in Nevada, Rhodesia is a poor goldfield." This may be changed to:

"I would consider Rhodesia a poor goldfield, as compared with Nevada."

Take care that your demonstrative pronouns are made to refer to the right thing.

(13) "A number of mines have adopted the use of cars to take the place of 'cans'. *These* hold from 1500 to 2000 lb. apiece."

The second sentence refers to the 'cars', not the 'cans'.

"A number of mines have substituted cars for cans. The cars hold from 1500 to 2000 lb. apiece" or

"In a number of mines the 'cans' have been replaced by cars, which hold from 1500 to 2000 lb. apiece."

(14) "Because a process is cheap does not prove it desirable."

(15) "It is because he was a scientific man that he insisted upon research."

---

*A chapter from a forthcoming book on 'Technical Writing', based on a series of lectures delivered at the University of California; to be published by John Wiley & Sons, New York.

In these two examples the causal clause is made substantive, thereby producing an awkward inversion. It would be better to write:

"A process is not desirable merely because it is cheap."

"He insisted upon research because he was a scientific man."

Kelley says:[1] "It should be insisted on again and again that if two forms of expression are both open to criticism, the chances are very large that something else could be better than either. Begin anew, and hammer out for yourself a sentence to which you can think of no reasonable objection. So a young writer learns his trade, and so a veteran keeps his style fresh and clean."

I should delete 'on' after 'insisted'; also the 'very' before 'large'; again, I should avoid the preposition-verb 'think of' and say "a sentence to which you can see no reasonable objection." However, the advice is admirable.

Do not compare things with qualities, the concrete with the abstract. Correspondence in form promotes lucidity and ease of statement.

(16) "He saw these issues more clearly than any [other] man."

(17) "No *other* man in the country has done more to advance the study of economic geology."

In the first quotation the 'other' is needed; in the second, it is out of place.

An intelligent interest in the rules of composition need not stiffen the writer's manner, nor make him pedantic.

Connectives should be placed carefully, and when used in couples they must correspond.

Both, and:

(18) "I went both because I feared and because I hoped."

Either, or:

(19) "The division of profits made by *either* governments, banks or industries."

Delete 'either' and insert a comma after banks.

Not only, but also;

(20) "This was not only according to law, but also according to justice."

On the one hand, on the other hand;

Neither here nor there.

(21) Either in the city or in the country.

Do not omit to repeat the preposition.

(22) "Poets are either born in London or remote country places."

The 'either' is misplaced and 'in' is omitted before 'remote'.

"Poets are born either in London or in remote country places."

Neither, nor:

(23) "I looked neither forward or back."

This likewise contains two errors:

"I neither looked forward nor back."

These seem small matters to the slovenly writer, but they are of the essence of clear writing. As Kelley says:

"No great difference? There is no great difference between lifting two pounds and lifting one pound; but I will not have my shoes weighted with lead. In the single and simple case, no great difference; but construct a complicated sentence in defiance of the laws of thought, or a long discourse with constant disregard of what is normal in structure and formally clear, and the reader will be wearied and repelled, unless your work is in other respects so good as to please him in spite of your slovenliness—and even if you please him, very likely you will have failed to make him understand you, and thereby to persuade or convince or instruct him as you would wish to do."

Young writers drift easily into long sentences, entangling their ideas in a wilderness of words. They shun the short sentence, preferring to link one thought to another by the aid of many 'ands', as an after-dinner speaker ekes out his lame remarks with a frequent 'urr' or 'err'. To err is human, to forgive divine; but it is hard to condone the unnecessary 'and'. Don't be afraid of short sentences or of using the full stop.

(24) "This quality of diffusion indicates molecular mobility; *and* a good example of this is furnished by etc."

"This quality of diffusion indicates molecular mobility, a good example of which is furnished by etc."

(25) "The methods employed in the underground work vary with the nature of the ore deposits *and* have been developed to suit the local conditions encountered in the various mines."

This is verbose and confused.

"Mining methods have been developed to suit local conditions, as modified by the varying structure of the ore deposits."

(26) "At the Zaaiplaats tin mine the cassiterite has mainly occurred in the Red granite; *and*, the author particularly notices that the color of granite round the pipes was often of a much deeper red; *and*, that a great deal of tourmalinization had taken place."

This requires several corrections: "At the Zaaiplaats tin mine, the cassiterite is found chiefly in the Red granite. The color of this granite is deeper in places around the pipes [ore-chimneys], where also tourmalinization is marked."

Such sentences are written by men that cannot claim lack of experience in writing. Here is a shocking example from the 'Times', of London:

(27) "The cities we remember from childhood, unvisited since, grow in our minds *and* become glorious *and* visionary. The memory itself is only a material which the mind uses, as in dreams it uses some fact of waking hours. There was a bridge, perhaps a mean iron bridge, *and* a few trees, *and* some decent houses beyond it. But all the mean details are forgotten, *and* the scale is so altered that the bridge seems to have spanned a deep valley with great arches, *and* to have been a causeway leading into a city of palaces *and* overshadowing trees. *And* along the causeway crowds were drawn into the city

---

[1] James P. Kelley, 'Workmanship in Words'.

and traffic coming from a great distance, as if to a festival. *And* there is a memory also of the sky itself as momentous—towering clouds flushed with the sunset, *and* the causeway shining after rain, *and* all the people in the streets enjoying the beautiful hours, with music [that was really a German band] adding a glory of sound to the glory of light *and* form *and* movement.''

The excessive use of 'and' spoils an excellent piece of writing.

'And' is used as a feeble continuative by writers uncertain of the relation between their ideas.

(28) ''Jackson went *and* examined the pump.'' That might be true; he might have gone toward the pump and then incidentally he might have examined it; but what the writer really meant was:

''Jackson went to examine the pump.''

(29) ''He told him to be sure *and* [to] attend to this matter.''

(30) ''When costs in California and Europe were compared—$75 here *and* [as against] Spanish mercury imported at $40 per flask—it became evident that an import duty was desirable.''

(31) ''It *is sometimes* [may be] found that the screening from one lot of ore is sufficiently rich to be shipped with the selected ore *and* [whereas] that from the next lot will be too poor.''

(32) ''Practically all the belts are 30 in. wide, 7-ply, *and* have $\frac{3}{16}$ in. rubber cover on the carrying side, *and* $\frac{1}{16}$ in. on the pulley side.''

We see what he means, but it can be said more clearly:

''The belts are 7-ply and 30 in. wide; they have a $\frac{3}{16}$ in. cover of rubber on the carrying side and $\frac{1}{16}$ in. on the pulley side.''

(33) ''The mining world is indebted to the initiative of John Wiley & Sons for meeting so great a want, *and* they have been fortunate in securing the services of Mr. Peele as the guiding spirit to translate the conception into achievement.''

Here the 'and' is introduced to correct a badly organized statement. When re-written it reads thus:

''John Wiley & Sons have placed the mining world under obligation through their initiative in meeting so great a want, and they have been fortunate in securing, etc.''

(34) ''Wet methods of treating the concentrate were not at all satisfactory, as there was a large amount of black residue in the concentrate that could not be decomposed by sulphuric acid and ferrous sulphate, *and which* carried high silver values.''

If 'which' is replaced by 'that', the last clause would refer back to 'residue', but the chief fault lies in tying an important assertion to the end of the opening statement by means of the 'and'. He means:

''Wet methods of treating the concentrate proved unsatisfactory because it contained a large proportion of black residue, rich in silver, that could not be decomposed by sulphuric acid and ferrous sulphate.''

(35) ''It is obvious that the calculations can be shortened when one set of apparatus *and* conditions are used continuously for analyses.''

He is connecting unlike ideas in a confusing manner.

''It is obvious that the calculations can be simplified by using the same apparatus under identical conditions during a series of analyses.''

Sentences without logical connection should not be linked by a feeble 'and'. The reason for the connection should be made clear by using the proper connective or by inserting an explanatory clause.

(36) ''For the retorting of lean shale, the Scottish retort gives fairly satisfactory results, but it is by no means perfect, *and* [although] it has been claimed that it is possible *to so* [so to] improve the retort as to make it less costly both to construct and to operate.''

(37) ''It is certainly not wise to construct small plants which are to be operated to recover both oil and nitrogen contents, *and* it will be especially poor business should it be also necessary to manufacture the acid required for the production of ammonium sulphate.'' I suggest:

''Certainly it is not wise to erect small plants that are to be operated to recover both the oil and the nitrogen contents, more particularly in a locality where it becomes necessary also to make the acid required in the production of ammonium sulphate.''

Adjectives should follow each other in the order of thought.

(38) ''The orebodies are easily mined and large.''

The 'easy mining' is a consequence of 'largeness', and that is the order in which the adjectives should be given.

(39) ''The ore is subjected to costly and prolonged treatment.''

The idea of costliness follows upon the prolongation of the treatment.

Such inversion of adjectives is tiresome to the reader and detracts from the force of the statement.

Place subordinate words in obscure positions, so as to leave important words where they are clear and disentangled from other words that clog them. Avoid emphasis on words that do not ''deserve distinction.'' Monosyllables usually make a feeble ending for a sentence. Lord Shaftesbury, in his 'Advice to an Author', says: ''If, whilst they [writers] profess only to please, they secretly advise, and give instruction, they may now, perhaps, as well as formerly, be esteemed, with justice, the best and most honorable among authors.''

That is a complex sentence so well arranged as to be perfectly clear.

Adverbs are commonly misplaced. Put the modifying word as near as possible to the word that it modifies. ''The ore should properly be dried'' does not mean that ''the ore should be dried properly.'' The first refers to the need of a particular operation, the other to the need of conducting the operation in a particular way. ''The words and groups of words that are near to one another in thought should be near in expression, and those that are separate in thought should be separate in expression.''[2]

---

[2] A. S. Hill.

(40) "Such errors are frequent in the writings *even* of good authors."

The 'even' should follow 'frequent'.

'Only' and 'always' are commonly misplaced.

(41) "His exordium would have been admirable if *he only* had spoken; but Mr. Asquith's significant reference to future relations aroused speculation instead of stilling it." 'New Republic'.

'Only' should precede 'he'; the writer means that it would have been better for the purpose if Mr. Lloyd George had been the only speaker. As it is, the sentence expresses the wish that he had spoken.

(42) "The internal-combustion engine has been introduced on a large scale in refrigerating plants *only* in the last three years." This is correct, but it would be clearer if the 'only' came after 'years'; the statement might be taken to mean "in refrigerating plants only."

(43) "It is necessary to *always* roast the ore before chlorination" and "It is necessary to roast the ore *always* before chlorination" are both objectionable. In the first, 'always' splits the infinitive; in the second, it qualifies the wrong word. The sentence should read:

"Before chlorination, it is necessary *always* to roast the ore." This introduces 'chlorination' ahead of 'roasting' and is preferable to "It is necessary *always* to roast the ore before chlorination," because the necessity for roasting arises from the use of chlorination; therefore the ideas should be expressed in that order. As a grammarian would say, "Before chlorination" is the antecedent clause, and "it is necessary, etc." is the consequent clause.

Do not bring two verbs, belonging to different sentences, into close contact, as in the following quotation from the 'New Republic'.

(44) "What the more serious evils of that policy are *was* revealed by the election."

It were better to have written:

"The more serious evils of that policy were revealed by the election."

I shall not castigate the split infinitive; the use or non-use of it is a matter of taste. You should try not only to avoid splitting the infinitive but to keep your verbs intact. Thus do not say "The ore has never been so cheaply milled" but "The ore never has been milled so cheaply." In the first the verb 'has been milled' is dismembered into three parts by the intrusion of the adverbs.

The split infinitive, however, is more than a breach of good taste, despite the sanction of usage as cited by an eminent critic.[3] It suspends the sense. A similar error is that of interpolating words between the definite article and the noun, as in "the already deep shaft has been sunk another hundred feet." Those who write thus are also likely to say:

(45) "We today find nothing peculiar in this."

The emphasis is on 'today', which therefore should come first, instead of separating 'we' from 'find'. It is curious that such splittings, of the infinitive and of other verb phrases, are usually employed for emphasis, which can be obtained much better by other locutions. Such suspensions are "ugly in form as they are awkward in sense."[4]

Here is one from the 'New Republic':

(46) "Our men of wealth have accepted *profits and income taxation* with a better grace than those of any European nation, with the exception of England."

The reader wonders why it is necessary to say that rich men have accepted "profits and income", and is jarred by the statement, before he reaches the word 'taxation'. The quotation is an example of sloppy writing. 'Rich men' is better than "men of wealth"; 'except' is better than "with the exception of." The writer wallows in indirect reporter-like phraseology. He might have written:

"Our rich men have accepted the taxation of their profits and incomes with better grace than those in Europe, except England."

Similar suspensions are common in technical writing.

(47) "As between fine and coarse ore crushing, he recommended the Gilpin county type of deep-mortar long-drop stamps."

Here the interposition of 'fine and coarse ore' suspends the sense until 'crushing' is reached; similarly a long adjectival phrase intervenes between 'recommended' and 'stamps'.

"As between crushing fine or coarse, he recommended stamps of the Gilpin county type, that is, a deep mortar and a long drop."

(48) "In the hard ground at Miami it is advisable to use a *wide shrinkage stope and pillar* system."

Here the five words preceding "system" are used as an adjective, suspending the sense too long. It would be better to write "system of wide shrinkage-stopes and pillars."

(49) "In sending *in* orders it was *very* necessary to give *full shipping and marking* directions."

'In' and 'very' are redundant. The four words preceding 'directions' are an adjectival jumble. He might have written:

"In sending an order it was necessary to give full directions for shipping and marking."

Directness of statement is an aid to clearness. As Horn Tooke said: "The first aim of language was to communicate our thoughts; the second, to do so with dispatch."

(50) "So the new order strikes at the root of much of the difficulty that has disturbed the industrial world since the War began *by applying only to the unskilled.*"

The clause italicized should come after 'order', which it explains.

(51) "It might have been appropriate to have *developed* [provided that] these particular resources of manganese and platinum, so forcibly cited as an argument for shoving the Bill through the Senate, [should be developed] under the direct control and management of a Government bureau for the pecuniary benefit of the actual owners in law and equity."

Here the principal word 'developed' has been mis-

Lounsbury.

[4] Allbutt. Op. cit. Page 82.

placed, so as to mar the directness of statement.

(52) "What is regarded as a significant fact is that as yet the President has not yet officially announced the re-establishment of the present price as effective from June 1 to August 15, although the War Industries Board has so recommended."

It was the disregarding of the recommendation by the Board that was the significant fact, therefore the statement should be re-arranged thus:

"That the President, notwithstanding the recommendation of the War Industries Board, has not yet announced the official re-establishment of the present price, effective from June 1 to August 15, is considered significant."

(53) "An applicant had to file a copy of these regulations, to show that they had been complied with."

He means: "to show that he had complied with them."

(54) "Before a hole drilled in the manner described is blasted, the hole is sprung by exploding in the bottom of the hole several charges of dynamite."

The clause "drilled in the manner described" is interjected awkwardly; it is superfluous. The statement can then be corrected thus:

"Before the hole is blasted, it is 'sprung' by exploding several charges of dynamite in the bottom."

'Sprung' is treated as an unfamiliar term and is explained by the last clause; therefore the single quotation-marks are desirable.

(55) "After a hole has been chambered sufficiently, the amount of which depends on the depth of the hole, the hardness and the tenacity and the volume of the rock to be broken, the hole is loaded for the final blast."

This statement contains several unnecessary inversions. The comma after the second 'hole' is not followed by a second comma after 'hardness', so that the continuity of the statement is broken. He might have written:

"The hole is loaded for the blast after it has been chambered sufficiently, this depending upon the depth of the hole, as well as upon the hardness, tenacity, and volume of the rock to be broken."

You will find it advantageous to place sundry adverbs, especially those of time or place, either at the end or at the beginning of a clause, gaining emphasis thereby. Thus:

(56) "Lately the ore has been crushed to 100-mesh" or "The ore has been crushed to 100-mesh lately."

The first is preferable; either is better than

"The ore has lately been crushed to 100-mesh."

(57) "The vein is frequently faulted along the upper level."

Here the idea to be expressed is the repetition of faulting particularly on the upper level, therefore re-arrange thus:

"Along the upper level, the vein is faulted frequently."

So the most significant words are placed in the most prominent positions, at the beginning and at the end of the sentence. 'Along the upper level' and 'frequently' are emphasized. But 'frequently' carries the idea of time; substitute 'at many places'.

Aim at correct emphasis, but do not carry the effort to the extent of cultivating a mannerism. My purpose, in analyzing the foregoing examples, is to suggest the undesirability of separating the parts of a verb by an adverb or an adverbial clause. It has become common to say:

"It certainly is"

"It sure did"

and it is just such vulgarisms that mislead the student into illiteracies from which he finds it difficult to escape.

The habitual use of slang, including a decorative kind of profanity, is detrimental to the acquirement of skill in the correct expression of ideas. Slang beggars the vocabulary; profanity ignores it. The word 'damned' has to stand for a host of adjectives and things 'go to hell' in a thousand ways.

Chemicals Used and Costs at Benguet, Philippine Islands

The following figures were sent by C. M. Eye, superintendent for the Benguet Consolidated Mining Co., whose mill in 1918 treated 23,539 tons of ore assaying $21.35 gold per ton. Of this, 89% was extracted, using the following chemicals and costs:

Chemical	Pounds, per ton	Chemical	Pounds, per ton
Lime	10.00	Flint pebbles	3.77
Sodium cyanide	1.15	Mine rock, substitute for pebbles	6.70
Zinc shaving	0.72		

Cost	Centavos* per ton	Cost	Centavos* per ton
Lime	16	Lead acetate	3
Cyanide	83	Lubricants	4
Zinc	34	Fluxes and crucibles	24
Flint pebbles	27	Oil for melting	11
Mine rock	5	Acids	3
Battery renewals	12	Mine timber	87
Tube-mill liners	25	Lumber	17
Machinery renewals	17	Explosives	18
Piping and packing	10	Candles	16
Belting	13	Cars and track supplies	7
Mill tools	4	Mine tools	9

*100 centavos = 1 peso = 50 cents U. S.

The total cost of mining and milling was ₱11.89 per ton, of which superintendence was 44 centavos, labor ₱5.94, supplies ₱4.88, and general 63 centavos per ton treated. The direct cost of mining was ₱5.62, and of milling, ₱6.27 per ton.

Costs at the Falcon Mine, Rhodesia

Last year, this mine produced 37,701 oz. of gold, 80,528 oz. of silver, and 7,064,000 lb. of copper, from 170,074 tons of ore. Of this, 153,340 tons, assaying $5.10 gold and 2.19% copper, was concentrated by vanners and the Minerals Separation system of flotation, using eucalyptus oil. The ore was mined from a depth of 1000 ft. Departmental costs were as under:

	Per ton		Per ton
Development	$0.54	Sintering, smelting, converting	$3.40
Ore extraction	1.74	Royalty to Government	0.49
Transport, crushing, sorting	0.24	Realization charges	2.47
Stamp-milling	0.27	General	0.89
Tube-milling	0.22		
Concentrating and classifying	0.32	Total	$11.20
Minerals Separation flotation	0.62		

ANTIMONY consumption in the United States is normally 1000 tons per month.

Unloading, Crushing, and Screening at the Arthur Mill of the Utah Copper Company

By F. G. JANNEY

DELIVERY OF ORE. The ore comes from the mine in trains of 40 cars, and at a point 15.3 miles from Bingham, or 2 miles above the Magna plant and 2.6 miles above the Arthur plant, the ore is diverted from the Bingham & Garfield main line to the Arthur high-line tracks. From here the train descends on a 0.4% grade over a 150-ton Strait scale, equipped with a Streeter-Amet automatic weighing and recording device, on which the ore is weighed in the train, while moving at the rate of two miles per hour. From the scale the train descends on an average 0.4% grade to the Arthur load-yard, which has a capacity of 102 cars. From here the loads are delivered by a switching crew to two dumper-load tracks, each having a capacity of 21 cars. These tracks are laid on a 1.5% descending grade, and the loads are fed one at a time by gravity to the car-dumped mule-pit. From the pit they are elevated 21 ft. up an 11.5% grade by means of an electric 'mule', and spotted on the car-dumper platen.

After the car has delivered its load it is bumped off the platen by the following load, and runs by gravity down a trestle track on a 5% grade, up a kick-back, and into either of the three empty-yard tracks, one of which is provided for cutting out all 'bad-order' cars. From the car-dumper empty-yard, the capacity of which is 90 cars, the empties are either switched to the general empty-yard, having a capacity of 136 cars, or picked up by the road-engines in making up their trains.

UNLOADING PLANT. The haulage and dumper mechanisms are electrically operated, and were designed, fabricated, and erected by the Wellman-Seaver-Morgan Co., in conjunction with the Utah Copper company's engineers, to handle the cars of ore delivered by the Bingham & Garfield railroad.

The haulage mechanism consists of one Esselius patented 'mule' car, with necessary haulage and tail ropes for operating it, upper and lower by-pass gates to allow the 'mule' to return to the pit when the car is standing between the mule-pit and the car-dumper. It is operated by a 300-kw. hoist, and the controlling mechanism is automatic. This mechanism is designed to handle cars having a total load of 215,000 pounds up an 11% grade at a rate of not less than 30 cars per hour, which is the rated capacity of the dumper. See Fig. 1, 2, and 3.

The car-dumper consists of a heavy steel framework supporting a rotating cradle upon which is mounted a movable platen, which carries the rails for the ore-cars. The cradle is supported from one side by heavy pivot-pins secured to the framework; the cradle-nose is rounded and provided with heavy wearing-plates. The 300-kw. hoisting mechanism for rotating the cradle is placed in a housing at the top of the framework. At the rear of the structure are the counter-guides and weights, with their cables passing over sheaves at the top of the framework, returning to the cradle and the three car-clamps. After the incoming car has been pushed onto the platen by the 'mule' and properly spotted on the platen by the car-rider, the cradle-hoisting machinery is started and the first motion of rotation releases the platen, which then moves sidewise toward the dumping side of the cradle until the side of the car rests against the cradle-blocking. Continued rotation of the cradle turns the car over so that it is tilted to an angle of 75° from the horizontal, thus discharging the contents of the car onto a grizzley. In winter when frozen ore is being unloaded and when a full load clings to the car, the cradle is not allowed to rotate beyond an angle of 45° from the horizontal. To take care of this extra weight additional counterweights are provided; they are readily attached at the will of the operator. During the motion of rotation the clamps which hold the car securely to the platen are automatically set by means of heavy counterweights which travel in guides at the rear of the main frame, these counterweights being operated by means of ropes so arranged that the pressure of the clamps is equally divided on the two sides of the car. This arrangement of clamps is a distinctive feature of the machine and causes less damage to cars than any other type constructed. The motion is entirely automatic, being controlled by counterweights and not dependent in any way on the operator. After the contents of the car have been discharged, the cradle returns to its original position, and the platen moves out so that its rails come into alignment with the approach and outgoing rails. The machine is now ready for another loaded car, which, on entering the cradle, displaces the empty car.

This entire unloading plant is operated by three car-riders, one car inspector, and one dumper operator, who, from his cab on the car-dumper, hauls the car up the incline and onto the dumper, where it is discharged.

As a reserve in case it becomes necessary to shut-down the car-dumper, the cars may be delivered over an auxiliary track to primary-storage bins of 10,000 tons capacity, where they are dumped from the bottom by hand. On top of these bins are grizzley-bars spaced 12 in. apart. Any pieces too large to pass are broken by sledge-hammers. Below these grizzlies are others, set at an angle of 40°, spaced 2¾ in. apart, the bars being made of special

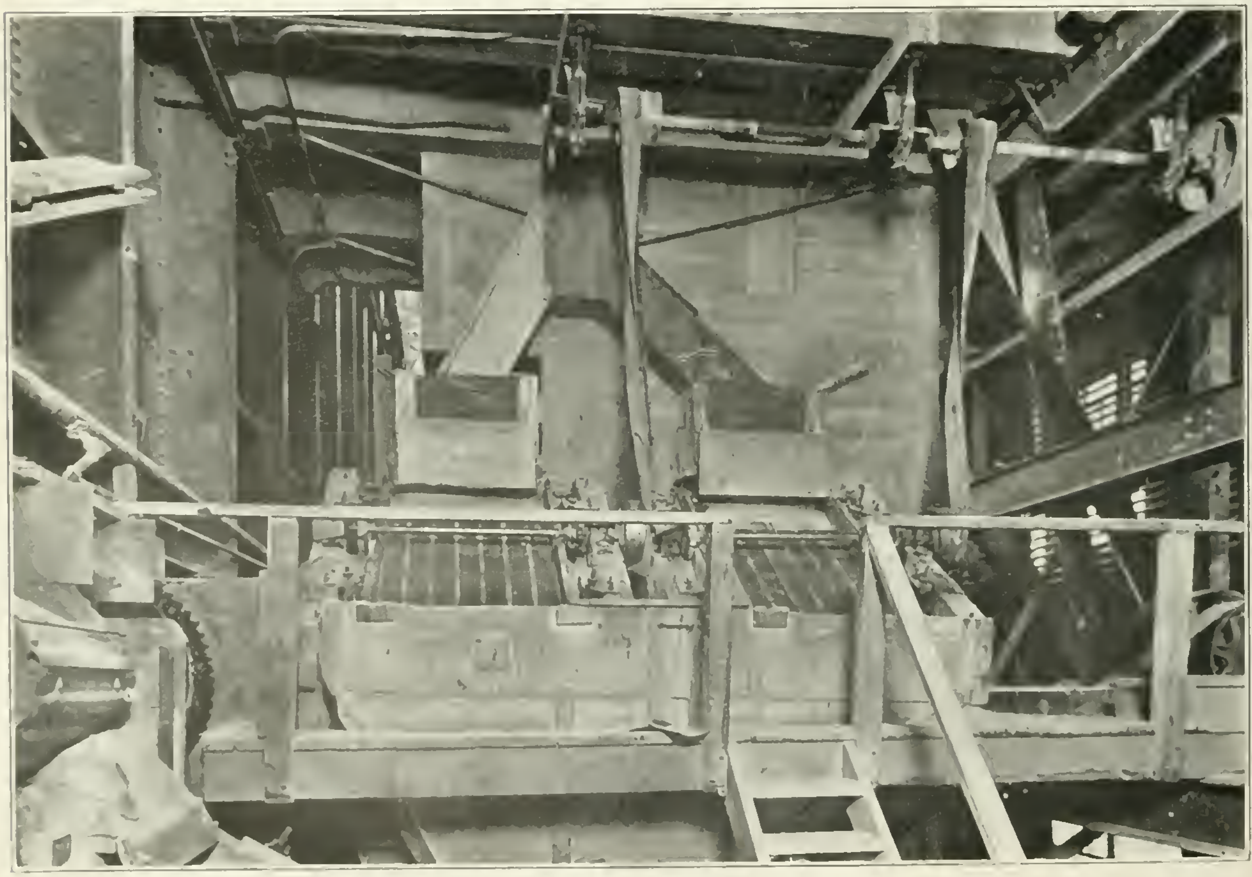

FIG. 8. ARRANGEMENT OF IMPACT-SCREENS WITH FEED-CHUTE

rolled steel. The oversize passes into pockets underneath and is drawn by steel apron-feeders, 48 in. wide, onto a steel pan-conveyor, also 48 in. wide. See Fig. 4. This carries it to two No. 8 McCully gyratory crushers, each of which serves a unit, and is supplemented by a spare crusher of the same kind available for either unit whenever required. The undersize of the lower grizzlies is drawn from pockets by steel apron-feeders 48 in. wide onto a rubber belt of the same width, which in turn delivers it to the first sizing-screen set an an angle of 42°, the apertures of which vary from 1 to 3 in. by changing the screen according to the character and moisture of the ore. From this point on the handling of the ore is the same as that coming from the car-dumper.

This system of unloading is ideal for seven months of the year—from March to November—except for those cars which are loaded with extra large rocks, the size of which prevents them from passing through the bottom of the cars, requiring hand-breaking from the cars and through the 12-in. grizzlies. During the period from December to February the ore freezes in the railroad cars to a depth of from 6 to 12 in. on the top, sides, and bottom of the cars. When the ore is frozen, the hopper-shaped bottom of the cars prevents its free discharge when the bottoms are dropped; an unloading gang of approximately 30 men per shift is required to pick and bar the entire contents of the car through the openings. The ore also freezes in the primary bins, and it appears to break more coarsely at the mine in the winter than in the summer, requiring excessive breaking of ore by hand in order to dump it through the first grizzlies. For these months the loss of capacity is equal to 25%, as well as being costly. These troubles are overcome by the car-tipple and the No. 27 gyratory crusher.

Returning to the car-dumper, the contents of a car, after being tilted, discharges onto grizzlies set at an angle of 35°, made up of 12-in. 28½-lb. Bethlehem I-beams, 7¾ in. by 32 ft. long, capped with a special manganese-steel casting. These built-up grizzley-bars are so spaced that the openings at the top are 5 in. and at the bottom 6 in., the object of this differential spacing being to prevent wedging of the oversize. The oversize passes to a No. 27 Allis-Chalmers gyratory crusher, with a double discharge, which, at the present time, is the largest ever built, designed to handle 54-in. material and reduce it to an average of 4½ inches. See Fig. 5. At the time this photograph was taken the bed of ore had not formed in the crusher-pit. This crusher is driven by a 300-hp. squirrel-cage motor at 600 r.p.m., direct-connected through a set of Wuest cut herringbone gears reducing the speed to 275 r.p.m. To take care of repairs on this crusher, the shaft and mantle of which weigh 55 tons, there is a 60-ton (with 10-ton auxiliary) 4-motor electric traveling crane. This crane also serves the drives on the 60-in. conveyors. The undersize from the grizzlies is collected in storage-pockets designed to hold 1300 tons of free-feeding ore, and is fed with the crusher-product by means of two 72-in. pan-conveyors discharging toward each other, onto a short grizzley with openings of 2½ in., to a 60 in. rubber belt conveyor, the function of the short grizzley being to produce a bed of fine on the belt-conveyor before the larger material, which has passed the crusher and grizzlies, reaches the belt. The 60-in. conveyor is 221-ft. centres, set at an angle of 18°, and is operated by motors the speed of which may be varied at the option of the operator in the secondary crushing plant by means of a push-button control from a minimum speed of 115 ft. to a maximum speed of 350 ft. per minute. The flexibility of this control makes it possible for the secondary plant to be run at its greatest efficiency, owing to its finer grinding and smaller capacity as compared with the primary crushing plant. The 60-in. belt-conveyor discharges onto a second grizzley, the bars of which are specially bulb-shaped, 25 ft. long and inclined at an angle of 45°. The openings of this grizzley are changed to suit the character and moisture of the ore. The oversize from the grizzlies discharges into three No. 8 McCully gyratory crushers, and, as previously mentioned, two of the crushers, each of which serves a unit, are supplemented by a spare crusher of the same kind, available for either unit whenever required. It is at this point that the ore from the reserve crushing plant joins the circuit. The undersize from these grizzlies discharges onto two short rubber belt-conveyors, 36 in. wide, 20 ft. long, operating on an angle of 16°, at a speed of 400 ft. per minute. Serving each of these conveyors is a screen, 40 in. wide, 10 ft. long, and set at an angle of 45°. These screens take out the minus 1-inch material, which passes by means of a chute to rubber belt-conveyors delivering to the fine-crushing department. The oversize from this set of screens by-passes the McCully crushers but unites with their product.

This description is confined to one of the two units into which the car-dumper is divided, as each side of the crusher-discharge is an independent unit.

The crushed product and screen-oversize are now divided into two parts, one going to the new roll installation and the other to the old. That portion going to the new is collected on a 60-in. rubber belt-conveyor, 25 ft. long, with a slope of 19°38′, and operating at a speed of 350 ft. per minute. The ore from this belt discharges to another conveyor running at right angles, also 60 in. wide, 150 ft. long, with a slope of 21°30′, traveling at the rate of 350 ft. per minute. This belt elevates and discharges into two 72 by 20-in. Garfield rolls of the moving pedestal type, operating at a speed of 125 r.p.m. The crushed product from each roll discharges on a separate rubber belt-conveyor, 42 in. wide, 118 ft. long, having a slope of 21°30′, and a belt-speed of 350 ft. per minute. At the terminus of each belt is a screen-tower, where the ore is delivered to four rotary feeders, each tower and set of feeders serving a roll. The feeders are 36 in. diameter, 64 in. long, and revolve at the rate of 2 r.p.m. Receiving the ore from each feeder is a 48 by 72-in. Mitchell vibratory screen. The oversize discharges onto a conveyor which runs horizontal at a speed of 250 ft. per minute. It is 42 in. wide, 25 ft. long, and discharges into a set of 72 by 20-in. Garfield rolls, operating at 125 r.p.m. The roll-product returns to the 60-in. conveyor feeding the first set of rolls. This puts the product in a closed circuit with one 60-in., two 42-in. conveyors, four sets of 72 by 20-in. rolls, and eight Mitchell vibratory screens, where it remains until it is all crushed to pass the screen-aperture. The undersize from the vibrating screens is conveyed by a 36-in. conveyor, 60 ft. long, operating at a speed of 340 ft. per minute, to the two conveyors, each of which are 36 in. wide, 150 ft. long, and traveling at a rate of 250 ft. per minute, which, in turn, discharge to similar conveyors 120 ft. long, which carry the ore to the secondary bins. The last two sets of conveyors serve both the old and the new coarse-crushing plants. That part of the feed passing to the old crushing plant is discharged to the boot of a 36-in. elevator equipped with staggered rows of buckets. This elevator travels at the rate of 350 ft. per minute and has a lift of 72 ft. From the elevator the ore is discharged into a chute having a screen-bottom 24 in. wide, 52 in. long, set at an angle of 45°, the aperture of the screen being one inch. The undersize passes by means of a chute to a 36-in. conveyor, which delivers to the 36-in. conveyors delivering to the secondary bins. The oversize is fed to a set of 72 by 20-in. rolls operated at a speed of 100 r.p.m. From the rolls this material flows down a chute, a portion of which has a screen-bottom 30 in. wide and 120 ft. long, placed at an angle of 40°. The screen has an aperture of one inch, the undersize to the conveyors delivering to the secondary bins. The oversize passes to a 30-in. elevator equipped with staggered buckets, the lift being 60 ft. The elevator discharges into a chute, a portion of the bottom being equipped with a screen 24 in. wide, 52 in. long, having an aperture of one inch and inclined at 40°. The undersize joins the belt-conveyors delivering to the secondary bins. The oversize returns to the last-mentioned elevator, which puts it in a closed circuit with the elevator screens and rolls, where it remains until crushed to pass the aperture of the screen.

THE VIBRATING SCREEN mentioned in the description of the secondary-crushing plant, has been developed by B. A. Mitchell, mechanical engineer to the Utah Copper company, during the last eighteen months and is now being placed in service. The principle is new and unique. The vibration is developed by a fractional horse-power motor which is totally enclosed with the vibration-producing mechanism, and, therefore, is absolutely dust-proof, fool-proof, and water-proof. This mechanism is underneath the screen-cloth (See Fig. 6) and in close contact with it at all times, transmitting its peculiar vibration to the tensioned (See Fig. 7) screen-cloth. This construction gives a free open screening surface for the material to be screened and for observation by the operator; it also permits rapid changing of worn-out screens. This type of screen requires fewer operators, less repairs and power (the power required being $\frac{1}{4}$ horse-power); it gives greater effective screening surface; therefore, greater screening efficiency than any other screening mechanism.

An idea of the character of ore mined and concentrated may be gained from the analysis which represents the ore milled for the month of November 1917:

	%		
Copper	1.27	Gold	0.0075 oz.
Iron	2.55	Silver	0.0675 oz.
Silica	68.80	Loss on ignition	1.85%
Aluminum oxide	14.56		
Sulphur	2.64		
Calcium oxide	0.22		
Potassium oxide	5.94		
Magnesium oxide	1.32		

The following is screen-analysis of the product as it left the crushing plant prior to the installation of the additional crushing machinery, and is therefore coarser than that which will eventually be obtained with the additional crushing arrangements.

Coarse-Crushing Product

	Mesh and opening	Per cent material	Accum % material
Opening	1.050 in.	1.17	1.17
"	0.742 "	8.44	9.61
"	0.525 "	22.27	31.88
	0.371 "	16.30	48.18
Mesh	3	12.11	60.29
"	4	7.24	67.53
"	6	4.07	71.60
"	8	4.27	75.87
"	10	3.61	79.48
"	14	2.82	82.30
"	20	2.31	84.61
"	28	1.92	86.53
"	35	1.74	88.27
"	48	1.55	89.82
"	65	1.53	91.35
"	100	1.27	92.62
"	150	0.82	93.44
"	200	1.07	94.51
Pass	200	5.49	100.00

From the bins the ore is drawn by steel apron-feeders adjustable to three rates of speed by step-pulleys, to which is attached a mechanical counter or tachometer, registering the number of revolutions of the head-pulley of the feeder, so that it is easy to adjust the proportion of tonnage passing into the thirteen sections into which the mill is divided.

The Transvaal in 1918

The Transvaal Chamber of Mines statement for December, just to hand, gives final figures for the past year, and comparing with the previous year, the following is the result:

	1918	1917
Ore hoisted (Rand only), tons	27,031,448	29,549,919
Waste sorted out (Rand only), per cent	7.80	7.73
Stamps dropping (Transvaal)	8,878	9,470
Days	278	301
Tube-mills grinding	338	332
Days	292	311
Ore treated (Transvaal), tons	25,267,302	27,862,851
Fine ounces	8,420,659	9,022,212
Total gold yield	£35,768,688 ($171,690,000)	£38,323,921 ($183,955,000)
Average per ton	28s. 1d. ($6.74)	27s. 3d ($6.54)
Working costs per ton	21s. 8d. ($5.20)	19s. 4d ($4.64)
Dividends paid	£5,273,633 ($25,315,000)	£6,718,604 ($32,251,000)

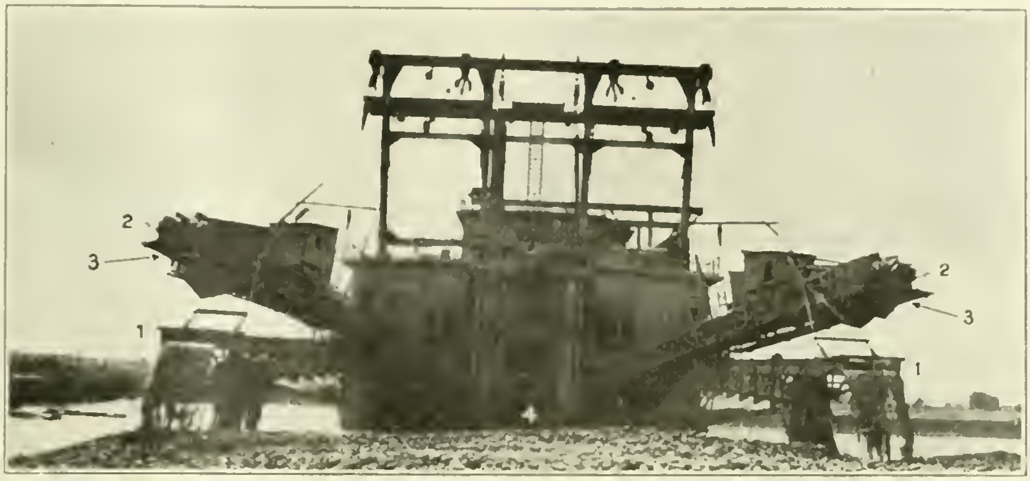
Operations in February were considerably affected by abnormal rain and floods; while September to December, inclusive, were severely affected by shortage of labor resulting from influenza. The outside districts contributed $4,540,000 to the total gold yield.

Prospecting at the Rooiberg tin mine in the Transvaal is done by hydraulicking, somewhat similar to the system at the Nipissing silver mine in Ontario.

Dredging and Re-Soiling

By M. W. von BERNEWITZ

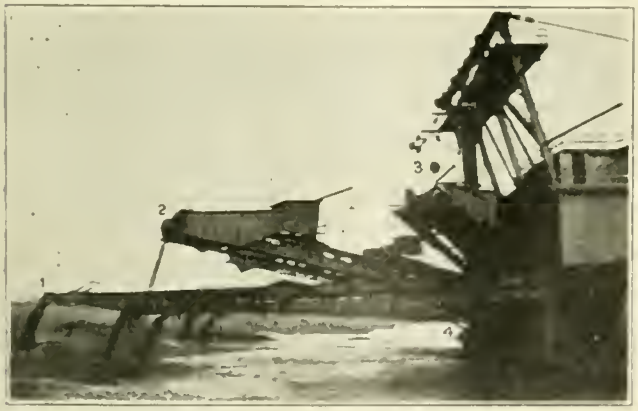
Two of the eight dredges operated by the Natomas Company of California near Natoma, east of Sacramento, are leveling the dredged ground. They, No. 1 and 4, have dug about 250 acres each. The final condition of the ground is almost as level as before starting, especially where No. 4 is working. This area has been partly planted with figs and alfalfa. These two boats have 15-cubic foot buckets, and No. 1—on which I spent a day recently—digging to a depth of 25 feet, handles 400 yards per hour. The gravel is free from clay.



STERN VIEW OF NATOMAS No. 1

1. Discharge-sluices. 2. Pebble-stacker. 3. Cobble-stacker. 4 Cobble-chute.

The principal difference between an ordinary dredge and one that is re-soiling, is that the discharge of the tailing necessitates construction of four stacker-belts and two long double sluices for water (this is clearly shown in the stern view of the boat), in place of one stacker and one sluice. This is why a re-soiling dredge costs a little more to operate than the ordinary type. The stackers require more power, and another man is needed.



SIDE VIEW OF STERN OF NATOMAS No. 1

1. Discharge-sluices. 2. Pebble-stacker. 3. Cobble-stacker. 4. Cobble-chute.

From the revolving-screen the washed gravel moves as follows: the sand and water flow over the riffles, where the gold is caught, and then flow to the ends of the sluices; the pebbles, up to say 4 inches, fall onto two belts that carry them 20 feet behind the sluice discharges; cobbles from 4 to 12 inches fall onto two belts which are, say, 20 feet shorter than the others; and cobbles of this size also fall down two chutes directly behind the stern, near the spuds. Therefore, the big cobbles drop first, the pebbles next, and the sand and slime last—on top of all. By the old system, all stones were dropped on the sand, the tail-sluice being much shorter than the stacker, making the unsightly heaps of tailing.

According to L. D. Hopfield, in charge for the company at Natoma, uneven bedrock makes it difficult at times to level the ground as well as desired; however, it seems as if good work were being done, the land being returned to a cultivable condition.

RE-SOILED GROUND. BANK AT LEFT NOT DUG

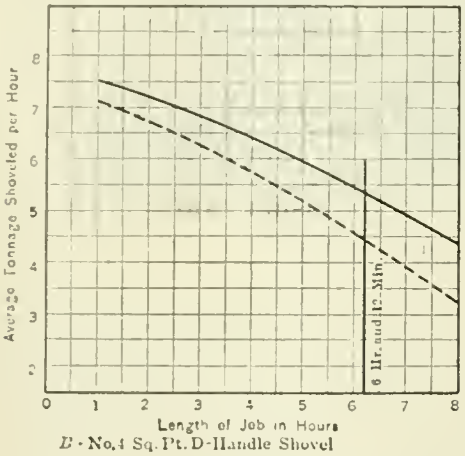
Shoveling

By G. T. HARLEY

*Conclusions from a study of shoveling at the Burro Mountain copper mine at Tyrone, New Mexico, presented the following points:

Shoveling ore cost so much at Tyrone during 1917 that it was deemed advisable to conduct tests to see where the fault lay. The tests were in the nature of time-studies, and extended over a period of nearly a year.

To obtain a basis for comparison, it was necessary to determine the capacity of various types and sizes of shovels, so as to know whether the 21-lb. load was the best load underground as well as on the surface. A list of essential factors influencing shoveling was also made out during the course of a short series of preliminary time-studies, and the motions involved in shoveling were analyzed and subdivided for convenience in studying. The necessary forms and record-sheets were also decided upon at this time. A second short series of tests was then conducted on the surface, so as to be able to estimate the negative effects of underground work on the shovelers, and to minimize, as far as possible, the need for studying obviously poor types and sizes of shovels under the difficult local conditions in the mine.



AVERAGE TONNAGE SHOVELED PER HOUR FOR ANY LENGTH OF JOB

The test work underground consumed most of the time and was divided into three series: shoveling directly into a chute, shoveling into a wheelbarrow and tramming to a chute, and shoveling into a car and tramming to a chute. In each series the following points were determined for various lengths of time worked: number of shovelfuls handled per minute, effect of distance thrown on shoveling speed, amount of rest required, amount of time consumed in tramming and dumping, proportion of working day occupied in shoveling, total tonnage handled during various working periods, effect of distance on tonnage handled during the day.

These tests showed that the design of the shovel has a marked effect on the shoveling efficiency, and that with the proper weight and size of tool the man's efficiency will be increased in spite of himself. It was shown that a man handling a total load of 26 lb. did the greatest day's work, other things being equal, and that this load is divided into a live load of 21 lb. and a shovel weight of 5½ lb. A shovel weighing 5½ lb., made out of the best alloy-steel, gives excellent service, and a lower cost per ton than a shovel having a lower first cost.

Further marked increases in shoveling efficiency are to be gained by instructing the shovelers in the proper methods of using a shovel, a thing that few laborers know, in spite of the fact that they may have been shoveling for years. Wages, the manner of paying the wage, and good-will are factors in efficiency work.

Scientific management systems applied to certain Eastern factories have proved conclusively that the efficiency of the average workman can be increased by from 50 to 250%, and at the same time the men will receive better wages, will remain in better health, and will be happy and contented, while the company will actually produce its products at a lower cost.

DESIGN OF SHOVEL BEST ADAPTED TO MINING WORK

F. W. Taylor, working at the Bethlehem Steel Co. plant several years ago, increased the capacity of the iron-ore shovelers from 16 to 59 tons per day per man, raised the men's wages from $1.15 to $1.88 per day, at the same time decreased the operating cost from 7.2 to 3.3 cents per ton shoveled. The increase in shoveling capacity amounted to 269%. Figures obtained at Tyrone indicate that the tonnage in at least one of the large stopes can be raised from 8.5 per man to 22.9 tons per man, an increase of 169%, the wages can be raised from $3.40 per day to $4, and the cost to the company reduced from 33 to 24 cents per ton, after taking care of all extra supervision needed. In addition to this actual saving in shoveling cost, the overhead and general mining charges will be reduced by mining a greater quantity per man; and the other classes of labor such as machine-miners and timber-men will be able to do more work, as they will not be hampered and delayed by the shovelers to such an extent as at present.

---

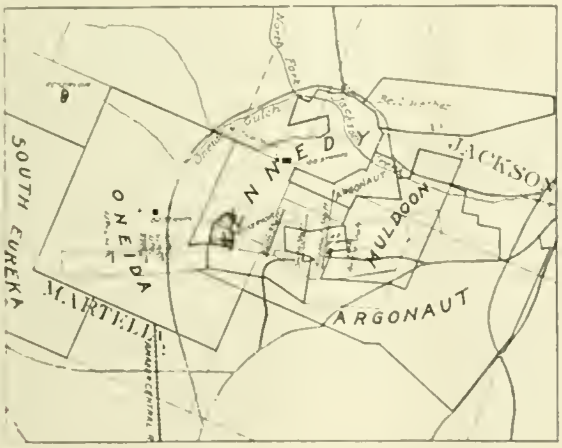
*Abstract from Bulletin 146 of American Institute of Mining Engineers, February 1919.

REVIEW OF MINING

JACKSON, CALIFORNIA

Serious Fire in Argonaut Mine.—Central Eureka Sinks.

Fire broke out on the 4000-ft. level of the Argonaut mine late on the afternoon of March 27. U. S. Bureau of Mines rescue-crews have arrived from Grass Valley and Berkeley. Up to the present, April 1, the fire is by no means under control. The fire-fighters have confined their efforts to bulkheading the shaft near the 3200-ft. level, and sealing the collar of the Muldoon shaft in an attempt to smother the flames. While the fire is believed to have started between 500 and 600 ft. back from the shaft, it is feared that it has burned close to the 3900-ft. station, on which is placed the immense underground hoist and valuable electric machinery; in fact, the woodwork in the station alone is said to be equal to the amount used in the construction of a good-sized dwelling. This station is equipped with a complete hoisting plant, practically a duplicate of the one on the surface, capable of hoisting from a depth of 7000 ft. Although the workings connecting the Argonaut and the Kennedy mine are closed, fumes and smoke have reached the north shaft of the adjoining property, and some fear is expressed as to the safety of men working in the Kennedy mine during the fire, the Kennedy's east or main working shaft being connected with the north shaft. Starting as it did during change of shift, the fire has so far entailed no loss of life. An engineer working at 3900 ft. was rescued after the fire was discovered, and two of the men working on the bulkhead on March 29 were overcome by fumes, but quickly resuscitated after reaching the surface. A gauge at the Muldoon shaft showed a slightly decreased air-pressure late that afternoon, indicating that the bulkheading of the shaft has had some effect. N. S. Kelsey, the company's superintendent, Edwin Higgins, safety and efficiency engineer, and W. F. Pyne, of the Industrial Accident Commission, and other prominent engineers are on the ground, and the neighboring mines are supplying all their trained men. It is hoped that the fire will be smothered before it reaches the shaft, but even if confined to the workings on the 4000-ft. level, the loss would be excessive, as the ground is heavy and the burning of the extensive timbering would cause serious caves. The Argonaut has a depth of over 5000 ft. on an incline of 60°. Including the men at the 60-stamp mill and surface employees, the cessation of work at this property throws over 200 men out of employment.



SKETCH SHOWING POSITION OF ARGONAUT MINE.

Telegraphic advice on April 1 stated that the fire was worse. A bulkhead was being built at 300 ft., as it was impossible to work much deeper in shaft. The Kennedy has been forced to close, as men are being gassed.

Sinking has been resumed at the Central Eureka mine, the intention being to put the shaft down 210 ft. farther, or to a point 280 ft. below the present lowest station—3500 ft. A winze sunk 100 ft. deep from 3500 ft. has opened some good ore, on which sufficient work has been done to warrant belief in its persistence. Contracts have been let for sinking, and two crews are working 8-hour shifts. During sinking, 20 or 25 stamps of the 40-stamp mill are profitably employed on ore from the stopes above the winze-level.

BISBEE, ARIZONA

Status of Employment.—Two New Mines of Promise.

Unemployment in the Warren district and at Douglas, the smelting centre for the ores mined here, while not alarming in its increase, has grown to such proportions as to demand public attention. The first real step toward relief was taken when a meeting of the Cochise County Community Labor Board, attended by the Board of County Supervisors and representatives of the mining companies, was held at the Y. M. C. A. building here on March 20. It was decided to issue a general call for attendance at a meeting of the supervisors to be held on April 8 at Tombstone. At that time, suggestions for relieving the situation will be asked for. The advisability of issuing bonds to cover road work in the country will be discussed. The way was paved by a bill recently signed by Thomas E. Campbell, Governor of Arizona, for county bond issues for road building during the emergency. In addition, the Community Labor Board adopted a resolution requesting that the Forestry Service, for which $9,000,000 was appropriated by the last Congress, expend a portion of the fund in improving roads leading into portions of the Coronado National Forest Reserve. The resolution recited the increase in the number of idle men in the State, but more particularly at Bisbee and vicinity, and the need for better roads. Reports of employment conditions in the district as given by representatives of the Phelps Dodge Corporation, Copper Queen Branch, and Calumet & Arizona company, indicated that both are maintaining their forces at the same level as earlier in March, with no additional curtailment considered at that time. Phelps Dodge has employed 164 soldiers and sailors in its mines here, while Calumet & Arizona has employed ninety.

Two new mines of importance will be added to the Warren district on the south side of the Mule range, at the extreme south-eastern edge of the hitherto recognized area of mineralization of the Bisbee circle. There are the Boras and Night Hawk leases, both of which are on Copper Queen ground, near the White Tail Deer mine of that property. Indications point to large orebodies in both leases, and their operators are hopeful. At the Boras, a shaft has been sunk to a depth of 250 ft., 100 ft. south of the incline shaft, in which ore originally was opened. A station was cut at 210 ft. and driving started to prospect the ground between the new shaft and the old incline. The chief work is being done in a northerly and north-easternly direction. Beneath the old incline, the same formation from which $25,000 worth of ore was shipped last year, was found. The ore was of practically the same width and carried the same average value, but the mineralized area was increased. More than 100 ft. of silicious ore carrying gold and silver was passed through before copper ore was opened. When the west drift had proved that at least two orebodies existed below the old incline, it was determined to sink an additional 100 ft. This work now is in progress. It is expected that the 300-ft. station will have been cut within the next two deeks, and the new drifts then will be started.——At the Night Hawk, the main shaft is more than 400 ft. deep. Some driving has been done, but in a winze 125 ft. deep, the first indications of ore in quantity were found. It has been decided to sink from 600 to 700 ft., and then prospect the ground overhead. The Night Hawk has shipped several carloads of ore to the Copper Queen smelter at Douglas, the returns aiding materially in paying for development.

Work at Sacramento Hill of the Copper Queen, where steam-shovels are removing the overburden from a great body of low-grade copper ore proved by diamond-drilling, is proceeding steadily.

TELLURIDE, COLORADO

What Snowslides are Doing in This Region.

The heavy storms that prevailed during the last days of February and the first week in March resulted in a number of slides, which blocked the Rio Grande Southern at a number of points, entirely stopping movement of ore. At Windy point, near Ophir, where there is a cut 500 ft. deep, the snow slid off the crest of the cut, filling the passage to a depth of 12 ft., and extending for a distance of 300 ft. This slide is the largest obstacle to clearing the road, being filled with trees and other debris, interferring with the operation of a rotary plow. A number of other slides resulted in loss and damage to the mines of the district, tramways being torn out, and boarding and bunk-houses smashed. Numerous narrow escapes are reported, but fortunately there is no loss of life nor severe injuries reported, rather remarkable considering the number and size of the slides. The Big Elephant Slide ran, damaging the electric surface tram that carries ore from the Tomboy mines to the mill, in addition to carrying off a section of the tram, taking out 100 ft. of snowsheds. A building was broken in, and part of the adit tramway carried out on the property of the Little Mary mine, when a slide ran down the gulch. The slide increased in depth and speed as it went down, striking the Humboldt tram of the Smuggler Union Mining Co. carrying away a section. Fortunately the tram has been idle since the closing down of the property a few weeks ago, and no one was injured. The Hanging Rock slide carried out a section of the Smuggler Union tram, and the power-line, interferring with movement of ore.

The Belmont Wagner company has completed the erection of the second Marcy mill, and is now ready to resume milling, and shipping concentrate as soon after April 1 as snow conditions permit. The management estimates that it will be producing an average of 45 cars of lead concentrate weekly.

CANANEA, MEXICO

Curtailment of Copper Operations.

The mine and smelter of the Democrata Mining Co. here were closed on March 15. The property is owned by the Hoffman interests of Cincinnati, Ohio, and is managed by C. E. Hoffman. Notices had been posted early in March announcing the impending suspension, setting March 25 as the date. However, a serious breakage of machinery at the works, that probably would require ten days longer to repair, resulted in decision to close earlier. Only a sufficient force to keep the property in repair and guard its equipment was retained. Several hundred men, mostly Mexicans, were affected.

The Cananea Consolidated Copper Co. has made no decrease in force since the heavy cut of several weeks ago when approximately 1500 men, or about one-third of its total, were discharged, and the output reduced to about half of normal.

Hermosillo.—The Hermosillo Copper Co., of which J. L. Zimmerman of Columbus, Ohio, is president, in its 7000 ft. of workings has a large quantity of copper carbonate developed. As this ore contains considerable lime, and scrap iron for precipitation purposes is difficult to get, the ore cannot be leached. Therefore efforts are being directed to finding sulphides. If these are opened, a flotation plant will be erected, while the sulphidizing of carbonate ore will then be tried. New machinery recently passed through Nogales on its way to the property, where 25 men are employed. Mr. Zimmerman states that the mine has never been molested, and the general feeling of the Mexicans there is friendly toward Americans.

CRIPPLE CREEK, COLORADO

Rich Ore Found in Three Mines.—A Profitable Lease.

"The richest ever handled in the ore-house at No. 2 shaft of the Portland Gold Mining Co.," is being mined at a depth of 2131 ft. from two veins under development from the Roosevelt tunnel, according to G. M. Taylor the general manager. On No. 1 Portland, the ore as broken from 6 ft. width assays from 15 to 25 oz. per ton, while the eastern core of the vein, an 18-in. streak, samples 160 oz. A 4-in. streak on the western side samples 60 oz. The shoot on the Lee No. 5 vein has been proved for 200 ft. south, and has been carrying 5 and 6-oz. ore, but at a point 30 ft. distant from the junction of the Lee and the No. 1 Portland, a sample taken gave 284 oz. It is expected that the shoot at the junction will be the richest opened in the mine. The elevation at the collar of the Portland No. 2 shaft is 10,244 ft., and at the point of discovery 8113 feet.

Rich discoveries have been made on the American Eagles and Longfellow mines of the Stratton estate on Bull hill. At the first-named, Basket & Luce have sunk a winze 125 ft. on ore from the 1500-ft. level, and are mining 8 to 10-oz. ore from an 8-ft. vein, by drift from the bottom of the winze. The second discovery was made by winze from the 500-ft. level of the Llewellyn shaft on the Longfellow. This property is operated by the Excelsior M. L. & E. Co. of Denver, under long lease. The ore shipped is returning 5 oz. per ton.

H. Chapman, lessee of the Elkton Consolidated, operating south of the shaft in the Thompson claim, at a depth of 600 ft., has cut a new and rich shoot in virgin ground. Four cars shipped during the present week from the discovery have been sampled by the Eagle Ore Co. in transit to the Golden Cycle at Colorado Springs, and returned 2.10 to 2.50 oz. No work has been done in the Thompson claim above the Chapman shoot, and it is believed that the ore will extend to the surface.

Carnduff & Duncan, lessees at the Dead Pine mine of the Granite company, surrender their lease this week after operating the mine continuously for seven years. During this time they have mined 30,800 tons of ore, ranging in value from $8 to $112 per ton. The gross production of the lease has been in excess of $500,000, and both of the operators have accumulated a good-size fortune.

THE MINING SUMMARY

Mining companies will be pleased to know that on March 24, prices of explosives were reduced by the du Pont, Giant, and Hercules powder companies. A comparison of prices per 100 lb. for standard strength—40%—and two other grades follows:

	Quantity											
	Car lots				Ton lots				Less than ton lots			
Explosive	Mar. 24	Dec. 13	Nov	Pre-war	Mar. 24	Dec. 13	Nov	Pre-war	Mar. 24	Dec. 13	Nov	Pre-war
Nitro-glycerine, 40%	$18.75	$20.75	$22.75	$11.50	$21.25	$23.25	$25.25	$13.00	$21.75	$23.75	$25.75	$13.50
Nitro-glycerine, low freezing 40%	18.75	20.75	21.25	11.50	21.25	23.25	24.75	13.00	21.75	23.75	25.25	13.50
Gelatin, 40%	18.25	20.25	22.25	11.50	20.75	22.75	24.75	13.00	21.25	23.25	25.25	13.50
Extra low freezing, 40%	16.50	18.00	19.00	14.25	19.00	20.50	21.50	15.75	19.50	21.00	22.00	16.25
Railroad powder, 5%	10.75	10.75	11.75	6.50	13.25	13.25	13.25	8.00	13.75	13.75	13.75	8.50
Quarry powder, 27%	17.15	18.15	19.15	10.00	19.75	20.65	21.65	11.50	20.25	21.15	22.15	12.00

ALASKA

In an instructive lecture recently given at San Francisco, Vilhjalmur Stefansson, the Arctic explorer, gave a good description of the climate and resources of Alaska, particularly concerning the possibilities of the Territory in raising reindeer for meat. His experiences in the North on living on the country instead of carrying all the food required, his methods of hunting and use of clothes, and building of snow huts were practical and should be of value to Alaskans. In hunting, he averaged two tons of bear and seal meat for each pound of ammunition expended.

Anchorage.—Advice from Washington, on March 25, stated that a commission, consisting of three naval officers, a mining engineer, and a geologist, will be sent to Alaska to plan development of the Matanuska coalfield. The commission was expected to sail from the Bremerton navy yard about April 1. The naval members of the commission have not been selected, but Sumner Smith, superintendent of mining in Alaska, and Thedore Chapin, a geologist attached to the Alaskan Engineering Commission, are to be the civilian commissioners.

Juneau.—The February Bulletin of the Alaska Bureau of Publicity states that from present indications, general business activities will begin in this Territory nearly a month earlier than usual. Vance R. McDonald, United States commissioner at Long, on Ruby creek, reports that there are large tracts of low-grade placer ground in this district that could be profitably worked by dredges. This ground may be purchased on favorable terms. Labor for ordinary work costs $5 per day with board. There is also said to be good chances in hydraulicking at Eagle. Quartz mining is reported to be on the increase. The Bureau is also conducting a central labor department, and has a list awaiting employment.

Unalaska.—The Alaska Sulphur Co. is about to commence mining sulphur on Akum island, 45 miles from this place and the first island west of Unimak pass, on the way to Bering strait. On March 23 the steamer 'Horace X. Baxter' sailed from Seattle, loaded with 1750 tons of supplies and men for the enterprise. Udo Hesse is engineer, and the firm of Reitze, Storey & Duffey of Seattle examined the deposits. They estimate 560,000 tons of 50% sulphur ore available. A 2-mile aerial tram will convey ore from the mine to tidewater. The president of the company is W. W. Johnson of Seattle, and T. H. Landewick of Chicago is secretary.

ARIZONA

Bagdad.—The Hillside Development Co., which is operating the Copper King property, is employing two 6-ton trucks for hauling high-grade zinc ore. A large tonnage is claimed to be available.

Jerome.—After four months delay in waiting for a new high-pressure compressor cylinder, operations at the Pittsburgh-Jerome will be resumed. Two headings and a 500-ft. diamond-drill hole are to be started as soon as air is available.

Mayer.—The tailing dump at the Boggs mine of the Commercial Mining Co. at Arizona City has been purchased by E. E. Hill of Mayer. This material has been on the dump for 25 years.

Oatman.—The United Eastern Mining Co. in 1918 extracted $2,138,417 from 92,339 tons of ore. Operations cost $797,760. In January 1919 the output was $210,767 from 8835 tons, yielding a profit of $129,000.

The United Eastern has filed suit against the Tom Reed company, at the same time making application for an injunction to stop the Tom Reed from mining in the disputed area. The injunction has been granted.

Swansea.—The Swansea Consolidated Copper Co. has suspended operations, 300 men being thrown out of work.

Tucson.—A. F. Borrego and J. R. Hibbs of Bisbee have taken a bond and lease on the Matt Perry Mining & Milling Co., a gold property. The mill is to be overhauled.

The Magma Chief Copper Co., which is operating the Sombrero Butte mine, has signed a smelter contract and preparations are being completed to ship the 10 cars of 21% ore ready. This has been sorted from ore extracted during development.

CALIFORNIA

Alleghany.—In the suit of William Flynn versus the Twenty-One Mining Co. to recover $25,000, alleging that the mine he purchased for $250,000, of which the $25,000 was paid down, was salted, Judge T. F. Graham last week at San Francisco decided that it was not salted. Judge Graham gave a decision in favor of Flynn in 1916, but on appeal, the mining company proved the mine had not been 'doctored' for Flynn's benefit before the sale. The Twenty-One company filed an appeal, but began to work the property itself. Within three months, more than $140,000 in gold was taken from the mine by the Twenty-One company. The Sixteen-to-One company, which owned adjoining property, brought suit in the Federal courts to enjoin the Twenty-One from working its claim, holding that the rich vein discovered in the Twenty-One was a continuation of the vein on the Sixteen-to-One. The injunction was issued. Because the $140,000 had been taken from the property after Flynn had given it up. Judge Graham decided the mine was not 'salted', and that Flynn is not entitled to get his money back on the ground he invested through false representation. In the 'Press' of March 22, in the Mining Decisions, we gave the text of the decision in the suit of the Twenty-One versus the Sixteen-to-One.

Castella. The Trinity Asbestos Mining Co., which has done some work on claims 25 miles from this place, has filed a petition in bankruptcy. Liabilities are said to be $230,000. H. H. Schmidt is the principal creditor. H. T. and E. R. Mecum, with O. L. Goodhue of Oakland were the principal owners.

Downieville.—The working tunnel at the Wehe gravel mine, at St. Charles hill, has advanced 800 ft. and is expected to reach a point directly under the channel within six weeks. From this point a raise will be driven to open the main channel.

The Brown Bear gravel property has been cleared of water, and three shifts are driving the main drift toward the channel.

Grass Valley.—At a meeting of the trustees of the city of Grass Valley on March 22, acting upon the advice of city attorney C. A. Armstrong, that body decided to contest the application of the Golden Center Mining Co. to have the Roche quartz claim on Marshall street declared mineral land and subject to a Federal patent as such. This decision was reached at a special meeting of the board, after much local dissension. The view taken by the board was that to allow title to the claims to pass to claimant from the city would be to establish a dangerous precedent, in that any other portion of this townsite might be declared mineral and subject to filings for quartz and go to patent. The Golden Center is asserting ownership to a strip of land 300 ft. wide by 1500 ft. long, occupied by residences generally, with enough land for its surface plant. The company is operating extensively in the heart of the city and has worked for several years without hindrance or molestation from any source until now. The plant consists of a hoist and mill. The claim in question was likewise an early-day mine, but allowed to lapse. There was no contest whatever at the time the United States patent was issued for the townsite in 1869, and nothing done of any consequence on this early day claim until now. M. J. Brock of Grass Valley is interested in the forthcoming action, and gave the board his views and information concerning the past status of the land. The opinion was freely expressed that if the Department should allow a patent to issue there would be nothing to hinder almost any piece being taken, as it all was considered mineral land prior to 1869, and a great deal of placer work was done within the confines of the present city limits. A hearing has been set before the Sacramento Land Office on April 22, and many of the early-day residents will be called as witnesses.

Kennett. The Shasta King mine near here, owned by the Trinity Copper Co., has been closed, the lease to the Mammoth Copper Co. having expired. For two or three years this mine has shipped ore steadily to the smelter at Kennett.

Placerville. The old Church-Union property, which has produced many millions of gold, was recently examined by Albert Burch of San Francisco. — Operations at the Lotus mine are to be enlarged by N. K. Cooper and J. E. Staratt. —The Burger mine is to be equipped with machinery. — The Manzaneta mine is showing a strong vein of rich ore. —The Rising Hope deep-gravel mine is yielding gold regularly.

Sacramento. The Senate Oil Committee voted on March 27 to report favorably Senator Ridgon's bill amending sections of the State Mining Bureau act relating to supervision over the petroleum industry of the State. The bill would add a paragraph to the section of the act authorizing the State Oil and Gas Supervisor to order tests or remedial work necessary to protect petroleum and gas deposits from damage by underground water, which would require the Supervisor or his representatives to deliver within five days to the operator a final written recommendation for the work in order that the owner may appeal to the district board of oil and gas commissioners which is elected by the companies. Another change in the bill would permit the State Mineralogist to appoint as supervisor a competent engineer or geologist experienced in petroleum development or an operator who has had five years experience in Californian oilfields.

COLORADO

Central City.—Mining is active in the Lake and Russell districts, there being 15 properties under development.

Lake City.—The Indiana-Colorado company contemplates erecting a 100-ton mill and aerial tram for its gold-silver property.

Ouray.—A six-mile railway between this place and Ironton will probably be surveyed this summer. This line will permit of the Sunnyside M. & M. Co. shipping concentrate throughout the year, instead of having the present outlet blocked by snow.

IDAHO

Mullan.—The National flotation mill was closed last week pending arrival of roll-shells, but it is not expected that the plant will resume until the copper market improves. On the 800-ft. level of the mine the ore recently cut out, but on raising to the east as good ore as previously mined was found.

The Old Hickory company has opened 2 to 4 ft. of ore for a distance of 300 ft. on the tunnel-level. The present depth is 600 ft. This is a new company, and is meeting with considerable encouragement.

Oakley.—The old Vipont silver mine, idle for 20 years, has recently been examined for Eastern and Utah capital. Phillips and Paddock are in charge at present.

MISSOURI

Joplin.—Production of the Tri-State region last week was as under:

State	Blende, tons	Calamine, tons	Lead, tons	Value
Kansas	1213	...	235	$62,855
Missouri	1701	410	111	86,377
Oklahoma	6122	...	781	292,521
Total	9039	410	1127	$441,753
Average price	$41	$27	$61	

The value was $31,000 less than in the previous week, but 1000 tons less lead and 1000 tons more blende was sold.

MONTANA

Butte.—The East Butte company's mining and smelting operations are now 70% of normal.

Clancy.—From the Free Coinage mine the Amalgamated Silver Mines Co. is shipping ore that settles for 129 oz. of silver per ton.

Troy.—The Liberty Montana Mining Co. has been organized by G. M. McKenna, J. T. Sugars, J. F. Powers, and others to operate 6 lead-silver-copper claims 5 miles south of this place. The main openings are by tunnels. A 50-ton mill, compressor, saw-mill, etc., are to be erected.

Wickes.—The Angelica Mining Co. is shipping 60 tons of $50 to $60 ore daily to Wickes. The tunnel is 4000 ft. long. A new strike is reported west of north-south fault, which threw the vein out of its course 400 ft. south. There is 5 ft. of galena at 900 ft. depth at breast of the 4000-ft. tunnel.

In the Lloyd-Crossley tunnel pay-ore has been opened in a drift west of the 3000-ft. tunnel. The ore is a gray copper, carrying silver.

NEVADA

Rand.—Shipments of highly siliceous silver-gold ore are being made from the Nevada Rand mine in Mineral county to the smelter at Kennett, California. Two cars went forward in March, returns from the first assaying better than $42 per ton. On the 150-ft. level, in ground south of the main drift, a 4-ft. face is worth $39, while below this level in the 200-ft. stope, high-grade streaks are being prospected assaying from $397 to $1766 per ton. This ore is being taken out on canvas and sacked for future shipment. Laterals are being extended south from the main 250-ft. drift to pick up the extension of this rich material. West of this section, from the 250-ft. level, a raise showing 2 ft. of $69 ore is being extended east, and a shipment will shortly be made from this point. Ore is hauled by auto-trucks a distance of 17 miles from the mine to Nolan station on the Tonopah branch of the Southern Pacific, at which point a spacious ore platform has lately been erected by the company. W. H. Bray, superintendent, is in charge of the mine. The company is controlled by W. V. Rudderow of Reno. A complete assay-plant has been built, greatly facilitating work. Further extensive development of the mine is contemplated. The property is 5 miles south from the Jumbo Copper Mountain mine and 1½ miles west of the Golden Pen mine, both of which have produced considerable good ore. Ore tests and mill data are being prepared by local engineers.

Tonopah.—Production of the district last week, including 245 tons from Divide, was 7074 tons valued at $120,258.

In the Belmont, the south vein has been opened on the 1100-ft. level. This is of much importance to the company. Work is to be resumed on the 1200 and 1300-ft. levels in a short time.

In the Extension, the Murray vein at 1680 ft. averages 12 ft. in width, although in places it is up to 30 ft. The mill, in charge of Hugh Burk, is extracting 94% of the silver and gold content.

UTAH

Alta.—The Michigan-Utah company's aerial tram, 4 miles long, severely damaged by snowslides a few weeks ago, is being repaired, the underground force being utilized. This tram carries ore from other mines as well.

Alunite.—The Mineral Products Corporation, mining alunite and extracting potash therefrom, closed its works on March 27.

Bingham.—The apex suit of Utah Consolidated v. Utah Apex is to be heard by Judge T. D. Johnson of the U. S. District Court at Salt Lake City on June 2. A great array of legal and technical talent will appear for both sides.

Eureka.—The Eureka Lilly company's shaft is down 1660 ft., equal to 1400 ft. vertical. Some formation carrying copper and lead was passed through. Gas was troublesome at times. Lateral work is to be started at once. Grant Snyder is manager.

Gold Hill.—The Western Utah Copper Co. has resumed operations at its mines and mill. It has been decided to continue development on the 700-ft. level, which is 300 ft. below the point where shipments were made last year. The 50-ton mill, erected last year at Salt Springs on the Western Pacific line, 27 miles north of the mine, is to be moved to the property.

WASHINGTON

Chewelah.—According to James Allen, of the State Highway Commission at Spokane, there is $360,000 available for improving the road between the Spokane county line near Deer Park, and Chewelah. This will also improve the bad road from Colville to Spokane.

Republic.—Ore production has been resumed from the Quilp mine, closed for several years. The previous output was gold worth $192,843 from 39,653 tons. W. G. C. Lanskail is in charge of 25 men.

CANADA

Ontario

Cobalt.—McKinley-Darragh is to start pumping tailing from Cobalt lake as soon as spring opens. The plant has a capacity of 350 tons daily. This material is to be treated in a flotation plant. On April 1 the company pays a dividend of 3%, equal to to $75,000.

The Nipissing company paid 5%, equal to $300,000, on March 31. The output in February was $243,176 from 125 tons of high and 6900 tons of low-grade ores.

Kirkland Lake.—It is officially announced that the Ontario government will build a branch line of the Temiskaming & Northern Ontario railway into this district.

Quebec

Quebec.—By the passing of a resolution in the Provincial Legislature on March 16, it has been decided to explore the territory of Ungava, or New Quebec.

MEXICO

The directors of the American Smelting & Refining Co are at present making a personal examination of its properties in Mexico. The following table gives the names and positions of the mines:

State	Unit	Mine
Chihuahua	Santa Eulalia	Mina Vieja
		Sin Nombre
		Velardena
		San Antonio
		Santo Domingo
	Magistral	Orizaba, La Union, etc
	Calera	Prieta and Buena Vista
	Dolores	Jibosa
	Cordero	La Luz and Paretonera
	Parral	Guadalupe
	Santa Barbara	Tecolotes and Montezuma
		San Diego and Alfarena
	Veta Grande	Veta Grande, Veta Colorado, etc
Coahuila	Sierra Mojada	San Jose
		Trinidad
		Volcan Dolores
Durango	Velardena	San Lorenzo
		Santa Maria
		Copper Queen
		Santa Juana
Aguascalientes	Asientos	Santa Francisca
Michoacan	Angangueo	San Cristobal, Carmen, etc.
San Luis Potosi	Charcas	Tiro General
	Matehuala	Dolores
Zacatecas	Bonanza	Bonanza

With fully restored economic and political conditions in Mexico, these mines, it is believed, will produce fully 2,500,000 tons of ore per annum. The smelters of the company are at Chihuahua, Monterrey, Aguascalientes, Matehuala, and Velardeña. All of these are now operating except the last, and they are of sufficient capacity to reduce the product of the above mines, except copper ores at Chihuahua, together with large additional tonnages under contract. There are certainly many reasons at the present time for feeling encouraged with respect to political conditions in Mexico, according to the annual report of the A. S. & R. Company.

Mexico

El Oro.—Esperanza in January treated 15,685 tons of ore, yielding a profit of $11,000.

Mexico City.—The New York 'Tribune' gives the following figures showing the financial status of Mexico:

National debt up to 1913	₱427,000,000
Interest past due and pending	75,000,000
Cost of the Civil War	125,000,000
Total public debt in 1919	₱627,000,000
Estimated revenue for current year	₱149,000,000
Budget for fiscal year 1917-'18	187,000,000
Mexican exports to United States in 1918	$140,000,000
Mexican imports from United States in 1918	106,893,653

The Chamber of Commerce Mexican Trade Excursion left San Antonio, Texas, on March 28. There were over 70 who received passports. The convention is thoroughly representative of the principal industries, and returns to San Antonio on April 13, after visiting Nuevo Laredo, Monterrey, Tampico, Linares, Saltillo, San Luis Potosi, the City of Mexico, Queretaro, Celaya, Iripuato, Guadalajara, Aguascalientes, Zacatecas, Torreon, and Piedras Negras.

Instructions have been given for the investigation and revision of all mining claims now in existence in the republic. Since the year 1910 there have been granted 9516 such claims, distributed as follows: State of Aguascalientes, 57; Territory of Lower California, 287; State of Coahuila, 426; Colina, 13; Chiapas, 17; Chihuahua, 1052; Durango, 775; Guanajuato, 548; Guerrero, 386; Hidalgo, 371; Jalisco, 428; Mexico, 310; Michoacan, 320; Nuevo Leon, 596; Oaxaca, 445; Puebla, 122; Queretaro, 240; San Luis Potosi, 444; Sinaloa, 632; Sonora, 1432; Tamaulipas, 69; Tepic, 92; Vera Cruz, 39; and Zacatecas, 539. Altogether, during the administration of ex-President Diaz, there were granted concessions of 56,000 mining claims, of which from 5000 to 6000 only were exploited.

MAP OF MEXICO

According to Manuel Aguirre Berlanga, a member of the Government, there is 700 miles of railroad construction under way in the republic. The Federal and State governments are defraying the cost. All of the materials for building the lines are obtained in Mexico. The cross-ties come from the native lumber mills and the steel rails are manufactured at the plant of the Monterey Iron & Steel Co. at Monterrey. The railroads now under construction by the Government are to run between Cuatro Cienegas, in the State of Coahuila, to Chihuahua, via Sierra Mojada, a distance of about 450 miles; from Durango to the Pacific port of Mazatlan, a distance of about 135 miles, and from Durango to Canitas, a distance of about 130 miles. All of these lines are important. The building of a railroad from Durango to Mazatlan has been under consideration for 30 years or more. Many surveys were made to locate an easy route across the Sierra Madres. This has been finally accomplished, and the road will be finished in due time, thus establishing a new transcontinental line across Mexico. The Cuatro Cienegas-Chihuahua line will be the means of opening to development vast coalfields in northern Mexico, while the Durango-Cienegas road will shorten the rail distance between Durango and the capital about 200 miles and will give a shipping outlet to some rich mining districts.

San Luis Potosi

Matehuala. The antimony mines and smelter of the Cia. Minera y Fundidora Internacional have been closed on account of the low price of the metal. During the War, when antimony rose to 40 cents, it was feared in the United States that the Mexican output would eventually depress prices.

PERSONAL

Note. The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

F. L. Sizer is at Tonopah.

L. D. Ricketts and **John C. Greenway** are at Santa Barbara.

Howland Bancroft, of Denver, was in San Francisco, on his way to Mexico.

Percy E. Barbour is now assistant-secretary of the American Institute of Mining Engineers.

H. R. Wagner has gone from San Francisco to New York, where he will remain for several months.

Victor Ziegler has resigned from the Colorado School of Mines and will open an office as consulting geologist in the Empire building, Denver.

J. P. Montague has resigned his position with the Ray Con., at Hayden, Arizona, to take charge of the mining interests of C. F. Wittenberg at Manhattan, Nevada.

Roy H. Allen has received his discharge as Captain in the Air Service and will be connected with the Research Department of the National Aniline & Chemical Co., at Buffalo.

Dwight E. Woodbridge recently addressed the Tax Committee of the House of Representatives of Minnesota on the pending bills for tonnage tax on mining companies of that State.

F. A. Fahrenwald has returned from western Canada where he has been engaged for some months in the examination of industrial resources, especially mining, metallurgical, and chemical possibilities, in districts west from Winnipeg, along the route of the Grand Trunk Pacific railway to Prince Rupert.

G. Lavignino, so active formerly in the mining industry in Utah and at Cripple Creek, Colorado, died at Pasadena, California, on March 27, in his 70th year. He possessed various mining properties at the time of his death. He was a man of broad culture, a linguist, and a student. He leaves a wife, a daughter, and three sons, the older at West Point, the second just honorably discharged from the U. S. Army.

Obituary

W. H. Steinman, blast-furnace superintendent for the New Jersey Zinc Co., died recently at the age of 61.

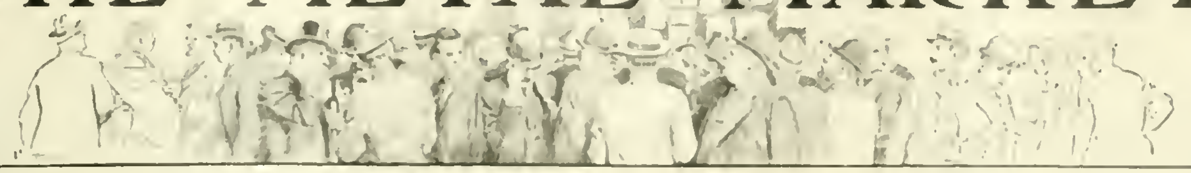
G. McGregor, deputy supervisor of the Department of Petroleum and Gas of the State Mining Bureau for the First District (Los Angeles), died at San Francisco on March 21.

George W. Myers, for 18 years the Pacific Coast representative of the Chrome Steel Works, Chrome, N. J., died of heart failure on March 28. He was a native of New York; 56 years old. He leaves wife and family. His son was connected with him in business.

H. R. Hancock, inventor of the jig and rock-drill that bear his name, and for 22 years in charge of the Wallaroo and Moonta copper mines in South Australia, died on January 15, at the age of 83. He was born in Devon, England, going to Australia in 1859. His eldest son, H. Lipson Hancock, now manages the Wallaroo and Moonta mines.

Edward F. Freudenthal, mine operator and promoter of Pioche, Nevada, died on March 24 at the age of 55 years. He was a native of Pioche and had always made his home there, although spending much time in Salt Lake City and in the East. He is survived by his widow, two sons, and a brother.

THE METAL MARKET



METAL PRICES

San Francisco, April 1

Aluminum-dust, cents per lb	60.00
Antimony, cents per pound	8.00
Copper, electrolytic, cents per pound, in carload lots	15.50
Lead, pig, cents per pound	5.50— 6.50
Platinum, per ounce	$100
Quicksilver, per flask of 75 lb	$68
Spelter, cents per pound	8.00
Zinc-dust, cents per pound	12.50

EASTERN METAL MARKET

(By wire from New York)

April 1.—Copper is quiet though strong. Lead is inactive but firm. Spelter is dull and easy.

SILVER

Below are given official (not Government) quotations, in cents per ounce, of silver 999 fine. In order to make prompt settlements with smelters and brokers, producers allow a discount from the maximum fixed price of $1.01½, hence the lower price. The Government has not fixed the general market price at $1, but will pay this price(as from April 23, 1918) for all silver purchased by it. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the current rate of exchange. On August 15, 1918, the Treasury announced that the maximum price was fixed at $1.01½ per ounce. The British government fixed its maximum at 40½ pence, on September 2, but on November 12 this was changed to 48¾, on December 13 to 48 7/10, and in February to 47¾ pence. On March 25, on account of the low rate of exchange, the London price was adjusted accordingly, resulting in fluctuations to 50 pence.

Copper stocks in this country are growing, and are now estimated at 1,300,000,000 lb., a gain of 300,000,000 lb. when compared with three months ago.

The members of the Copper Export Association are returning from Europe. They are reported to have no important orders for copper, but have a first-hand knowledge of conditions on the Continent.

TIN

Prices in New York, in cents per pound. The monthly averages in 1918 are nominal. On December 3 the War Industries Board fixed the price to consumers and jobbers at 72½c. f.o.b. Chicago and Eastern points, and 71¼c. on the Pacific Coast. This will continue until the U. S. Steel Products Co.'s stock is consumed.

PRICES OF OLD METALS

Business in New York is quiet, with the following prices in cents per pound:

Copper, heavy and crucible	13.00
Copper, heavy and wire	12.00
Copper, light and bottoms	10.50
Brass, heavy	7.50
Brass, light	6.00
Heavy, machine composition	12.50
No. 1 yellow rod brass turnings	7.00
No. 1 red brass or composition turnings	10.00
Lead, heavy	4.25
Lead, tea	3.50
Zinc	4.75

Eastern Metal Market

New York, March 26.

There is a better tone in most of the markets, and in some of them prices have stiffened; but buying has not been of large proportions, when judged by normal standards.

Antimony has declined and is quiet.

Copper is much more active at advancing prices.

Lead is easier and slightly lower, with buying almost negligible.

Tin it yet at a standstill.

Zinc is quoted a little higher, but there has been little demand.

ANTIMONY

The market is lower with demand light. Spot delivery of Asiatic brands is quoted at 6.25 to 6.37½c., New York, duty paid, for wholesale lots.

COPPER

In the last few days the market has assumed an entirely different tone, and taken on a spurt of activity greater than has been witnessed since the signing of the armistice. Since last Friday, estimates place total sales at not less than 35,000,000 lb., which would be more than in either January or February. It is also figured that in the last 10 days about 175,000,000 lb. has been sold. Neither of these reports has been confirmed. As a result of these facts the market has advanced gradually until today, March 26, yesterday being a holiday in honor of the parade of the 27th Division, electrolytic copper is quoted at 15.25c., New York, with Lake copper nominal at 15.50. Most of the sales referred to as having been made in the last three or four days probably went at 14.87 to 15.12½c. There has been no pronounced demand from foreign consumers, and little is expected for a month or more. The return in a few days of the representatives of the Copper Export Association from Europe will throw interesting light on this. Some say that the imminence of this information is back of the present buying of copper, while others think that the activity is to be short lived. On March 31 next the New York Metal Exchange will commence trading in copper. To meet new conditions and to measure up to the demand of an active market, the rules have been revised by the authorities so as to make them virtually satisfactory to all interests. Announcement has been made of the details of the selling of the Government stocks of copper. The United Metal Selling Co., acting for the producers, will sell 5,000,000 lb. per month for 10 months, and then 10,000,000 lb. per month for 5 months at market prices.

IRON AND STEEL

The price reductions agreed upon last week at Washington range from $4.25 per ton on pig-iron and $5 on billets to $10 on standard rails, and amount to $7 per net ton on plates, shapes, bars, wrought pipe, sheets and tin-plate, and $5 on wire, wire nails, hoops, and light rails. Eastern bar-makers have met the reduction on steel-bars by dropping their price from 2.90c. to 2.35c., Pittsburgh. The opinion is general in the steel trade, says 'The Iron Age', that the reduced prices will bring out in the near future a moderate amount of new business, most of which buyers have held up since the stabilizing movement loomed up six weeks ago.

LEAD

The lack of interest and demand has continued during the entire week, and the market is dull with the outside market at slightly lower levels The American Smelting & Refining Co. has not changed its quotation of 5.25c., New York, or 5c., St. Louis, but the outside sellers have shaded these proces to $5.20c., and 4.95c., respectively. Certain independents apparently have become restless, and attempted to attract consumers, but these have refused to be tempted. It is not believed that levels will fall much lower, not at least below 5c., New York, for the fundamental conditions of the market are sound. When buying in other raw materials commences, it is believed that there will be an active demand for lead. Stocks are low, and production has diminished to under 50% of capacity.

TIN

Another attempt has been made to force more quickly the allocated tin into consumer's hands by the rather drastic ruling that a leading American smelter of tin shall no longer sell 5-ton lots unrestrictedly, as has been possible up to now. This is regarded of course as a move to remove even this competition with the allocated metal which is fixed at 72.50c., the American tin having sold at a lower level right along to the detriment of the Government metal. It is said that if buyers will take the allocated metal, they will likely secure it at less than the fixed price when final adjustments are made. Spot Straits tin continues unchanged at the Government price of 72.50c., New York, with American 99% metal available at 68c., New York. No one seems able to fix a date as to when the allocated metal will be absorbed, and it is this on which the whole future of the market depends. According to the last estimates only 6000 tons of the original allocation of 10,000 tons has been booked. Arrivals so far in March have been 1425 tons of tin, all at Pacific ports—no more than a week ago. The London quotation for spot Straits tin is unchanged at $239 per ton.

ZINC

Producers generally have revised their ideas of market conditions and have slightly advanced their quotations to 6.17½ to 6.20c., St. Louis, or 6.52½ to 6.55c., New York, for prime Western for early delivery. To this extent the market may be regarded as firmer, but still quiet. The main reason back of this firmer tone is the expectation that galvanizers will purchase steel sheet-bars, now that a lower minimum price has been set, and hence will need more spelter.

ORES

Tungsten: There is little change, with still no testing of prices; therefore quotations are impossible. The buying of steel, expected to follow the fixing of prices, is expected to stimulate the tungsten market ultimately. The public auction of tungsten, scheduled for last Thursday, has been postponed until April 4. There are also no quotations for ferro.

Molybdenum: Outside of a possible demand from Great Britain, the market is without interest. Quotations are nominally unchanged at 80 to 85c., per lb. of MoS_2 in high-grade concentrate.

Manganese Alloys: Domestic producers of ferro have reduced their quotations of 80% alloy from $200 to $150, delivered, but there is no business. Consumers are well stocked apparently, and are buying only what they need as they need it, and mostly re-sale material at less than $150. Large quantities of British alloy are now coming in for delivery on old contracts, which call for some rather low prices ranging from under $50 to about $164 per ton, seaboard, but most of it is the higher-price material. It is stated that some of the lower-cost alloy is being re-sold at a profit.

Company Reports

BINGHAM MINES CO.

Property: the Dalton & Lark and Yosemite mines in the Bingham district, and the Eagle & Blue Bell and Victoria in the Tintic district, Utah.

Operating Official: Imer Pett, general manager.

Financial Statement: net receipts from all sources in 1918, including dividends from other companies, totaled $331,731. The surplus at the end of the year was $365,877.

Dividends: five of 50 cents each absorbed $375,000, making $562,500 to date.

Development: little development was done in the main workings of the Dalton & Lark, but new openings amounted to 2755 ft. A large tonnage should be developed on the Brooklyn, Lead Mine, and Lark veins below the Moscotte tunnel. Several lessees were at work.

Results on the Lead Mine vein in the Yosemite property were not satisfactory, but the ground is so favorably situated as to encourage further exploration.

In the Victoria there was performed 2313 ft. of work. The 1050-ft. level failed to reveal a downward continuation of the ore, but more success followed exploration of a probable upward extension to the main orebody. Recent favorable developments in the Eagle & Blue Bell at and below 1700 ft. emphasize the importance of the Victoria.

Prospecting and development—5519 ft.—in the Eagle & Blue Bell cost $52,589. Early in the year a considerable quantity of lead-silver ore was opened above 1550 ft., but later on this was more or less 'bunchy', requiring greater care and cost. In December, ore was found in a cross-cut driven east from the 1875 south drift, on a strong fissure. Nearly all levels above had been productive from orebodies found near this fissure, so the discovery is of importance. Much success and confidence has been obtained by carefully exploiting small showings:

Production:

	Dalton & Lark*	Yosemite	Victoria	Eagle & Blue Bell†
Ore, tons	31,670	2,010	6,791	40,370
Gold, ounces	1,666	80	1,048	2,605
Silver, ounces	172,564	10,189	139,304	579,075
Lead, pounds	1,326,636	314,258	176,019	9,389,376
Copper, pounds	875,006	21,034	165,508	16,012
Operating profit	$140,604	......	$44,319	$288,730

*Including lessees. †$267,914 paid in dividends, making $1,161,090 to end of 1918.

FALCON MINES, LIMITED

Property: extensive property and plant 60 miles west of Gwelo, Blinkwater district, Rhodesia.

Operating Official: C. E. Parsons, consulting engineer.

Financial Statement: sales of copper, gold and silver realized £485,406 ($2,320,000) during the year ended June 30, 1918. Operations cost £397,888 ($1,900,000). The profit was £88,449 ($420,000) plus £186,894 ($892,000) brought forward. After paying a dividend and allowing for taxes there remained a balance of £75,310 ($360,000).

Dividends: No. 1 of 20%, equal to £80,000 ($380,000) was paid.

Development: the main shaft was sunk 127 ft. to a depth of 1109 ft. All development covered 3808 ft., making over 5 miles of workings. A re-estimate of reserves shows 800,000 tons, averaging $5.40 gold and 2.32% copper, a decrease due to not including the recovery of certain broken and unbroken ore. On No. 10 level the orebody is 180 ft. long, 70 ft. less than on No. 9, but the width and value are similar.

Production: the mill concentrated 153,340 tons of $5.10 gold and 2.19% copper ore, producing 24,192 tons of vanner concentrate assaying $20.40 gold and 5.19% copper. This was smelted direct. The tailing from vanners, etc., was re-treated by flotation, which saved 18,010 tons of concentrate carrying $5.80 gold and 9.87% copper. This product was smelted. The total extraction was 81.9% gold and 87% copper. The smelter reduced direct 15,350 tons of $8.10 gold and 4.45% copper ore. The sintering-plant (16 pots) made 39,406 tons of product. The blast-furnace treated 80,559 tons of metal-bearing charge. The past four years yields are as under:

Year	Copper tons	Gold oz	Silver oz
1918	3,542	37,701	80,428
1917	3,414	35,248	70,876
1916	3,108	36,577	65,737
1915	2,574	31,401	53,403

This was extracted from 722,482 tons of ore. All costs were 46s. 9d. ($11.24) per ton in 1918.

SHATTUCK ARIZONA COPPER CO.

Property: mine and mill at Bisbee, Arizona.

Operating Officials: L. C. Shattuck, general manager; Arthur Houle, superintendent.

Financial Statement: the gross income in 1918 was $2,668,083. Operations cost $1,883,424, reserve for depletion $504,717, and depreciation $36,475, leaving a net profit of $243,467. The balance from 1917 was $1,003,129, and that carried to 1919 was $809,096, after deducting dividends and adding the profit for 1918. Current assets total $2,505,213, and liabilities $411,996.

Dividends: four absorbed $437,500, making $7,262,500 since 1910.

Development: to the 900-ft. level new work amounted to 15,125 ft., making 27 miles in all. Results were not favorable for copper ore, although between 800 and 900 ft. a large body of primary sulphides was exposed, carrying from 2 to 4% Cu. In the lead section good tonnages of 6% Pb, 8 oz. Ag, and $1.20 Au ore were developed.

Production: the lead mill, on which $294,902 has been spent, started in July, but electric power was short until November. This flotation plant dressed 27,851 tons of ore assaying 6.6% Pb, 8.1 oz. Ag, and 0.07 oz. Au. Results have not equaled experiments, and the loss of silver was excessive. The complete yields were:

Copper ore smelted, tons	91,092
Lead ore treated and smelted, tons	28,550
Copper, pounds	9,081,959
Lead, pounds	2,420,890
Gold, ounces	2,061
Silver, ounces	1,083,925
Operating cost per ton of ore	$14.125
Operating cost per pound of copper, cents	14.635
Price received for copper, cents	25.660

MOUNT ELLIOTT, LIMITED

Property: mines and smelter in the Cloncurry district, Queensland, Australia.

Operating Officials: A. E. Strick, mine superintendent; W. H. Corbould, consulting engineer.

Financial Statement: during the year ended June 30, 1918, a loss of £56,890 ($273,000) was made, after allowing for depreciation, etc., mainly due to the strike at mid-year.

Development: reserves in the seven mines total 1,861,000 tons. In Mt. Elliott is 600,000 tons of 3% and 10,000 tons of 10% ore, in Hampden Consols 450,000 tons of 4%, in Mt. Oxide 300,000 tons of 10%, in Argylla 200,000 tons of 4%, and in the limestone and jasper lodes of the Great Australia 203,000 tons of 2½ to 4% ore.

Production: 51,952 tons of ore smelted yielded 5,201,280 lb. of blister copper. Alterations to the plant were completed early in January 1918, since when it has worked well. The refinery produced 5,134,080 lb. of 'fire' refined metal.

Book Reviews

The Zinc Industry. By E. A. Smith. Pp. 223, ill., index. Longmans, Green & Co., London and New York, 1918. For sale by 'Mining and Scientific Press.' Price, $3.50.

It is several years since any new work has been written on zinc, during which time many new mines have been developed and advances made in the metallurgy, so this volume should fill the gap. From a preliminary perusal we find the book contains the latest information, although statistics are only up to 1914, showing normal pre-war production. A map and a graph show clearly the principal zinc centres and the production of spelter in the world since 1845. In the chapter on rise and progress of production of the metal, the establishment of smelters in Europe, America, and especially in Great Britain, are traced. Europe reduced large quantities of Australian concentrates, while England depended mostly on imported ores to keep its industry going. Certain phases of the War resulted in the question of the Australian product being reduced in England, and the erection of more smelters for that purpose. The last chapter discusses the future of zinc in that country. The Belgian and German works are covered, also those in America, too well known by readers to need extended reference. The world's ores and sources of supply, including Japan and Siberia, find complete notice. Concentration and marketing of ores and the metal are considered; but 45 pages are devoted to roasting and distillation, including the production of zinc-dust and such by-products as sulphuric acid, blue powder, lead, silver, and cadmium. The notes on costs are instructive. Electric smelting and electrolytic exrtaction of zinc are fully discussed. Producers in America have been alive to the extended use of spelter, so the properties and industrial applications of the metal will be found of value herein; also the alloys and pigments. Our complete study of the book finds it to be up to date. The binding is poor, and advertisements before the title-page are out of place.

Compressed Air Plant. The production, transmission, and use of compressed air, with special reference to mine service. Third edition, largely re-written. By Robert Peele. Pp. 485, ill., index. John Wiley & Son, New York, 1919. For sale by 'Mining and Scientific Press'. Price, $4.25.

The author of this important work, who is professor of mining in Columbia School of Mines, is well known from the previous editions of this book and as being editor-in-chief of the valuable 'Mining Engineers' Handbook', published in 1918. This new edition should be on the shelves of every mechanical engineer, especially at mines. While compressed air, as a prime mover, is an expensive power, yet it cannot be dispensed with, and its use grows. The design of compressors and machines using air improves continually, likewise the efficiency of compressed air. Compressed air is now almost indispensible in expeditious development of mines, in hoisting, in underground haulage, in metallurgical plants, in machine-shops, in tamping railroad tracks, in sand-blasting, in shipbuilding, and in forcing concrete mix into forms. Mr. Peele has restricted his discussions to deal only with the production of air and its uses in mining and tunneling. The loss of compressed air in pipes is relatively small; there is no problem of disposal of the exhaust, as when steam is used; and the exhausted air is of some assistance in ventilating underground workings. Air is far more preferable than steam for machine-drills and hoists; while no electric drill can compete with an air drill. In an early issue of the 'Press' we are publishing a paper on compressing air efficiently, in which is discussed the design of compressors, their lay-out, piping, inter-coolers, etc., and in Peele we find these topics much elaborated, and illustrated by modern machines—steam, water, and electric driven. The factors entering into the compression of air are somewhat intricate, but here are shown by formulas and diagrams. Air inlet and discharge-valves and mechanically controlled valves are the subject of much study by designing engineers, so 38 pages are devoted to it. As so many mines are at high altitudes, compressors have to be designed accordingly, their effective capacity being much reduced. For instance, the volume of compressed air delivered at 60-lb. pressure, at 10,000-ft. elevation, is only 72.7% of the volume delivered at the same pressure by the same compressor at sea-level. Or, a machine that will drive 10 drills at sea-level will only furnish air for 7 drills at the height mentioned. So mining engineers must not forget this important factor. Explosions occur fairly frequently in compressors and receivers, and while generally credited to oil vapors, the reasons are rather obscure. This subject is fully discussed. Air may be compressed by the direct action of falling water, some notable examples being given. The second part of Peele is devoted to the conveyance of compressed air in pipes and its use in rock-drills, hoists, pumps, coal-cutting machinery, channeling machines, and locomotives in mines. Every modern type of machine under these heads is described and illustrated. Air-lifts—mine and mill—are also discussed. Frequent references are made to the technical press, and manufacturers of apparatus pertaining to compressed air; and the costs cited are recent and instructive. Anybody having problems involving compressed air will surely find the solution in this excellent volume.

Handbook of Mechanical and Electrical Cost Data. By Halbert P. Gillette and Richard T. Dana. Pp. 1716, ill., index. For sale by 'Mining and Scientific Press'. Price, $6.

As the preface states, this book is intended as a companion volume to Mr. Gillette's 'Handbook of Cost Data', and Mr. Dana's 'Handbook of Construction Plant'. The arrangement is similar to the former book, but there is little overlapping. In these days of abnormal prices, and of discussion as to whether or not large reductions will be made in the near future, some engineers and estimators may feel that a book of cost data, since its costs manifestly cannot be brought up to the minute, is of slight value. That this viewpoint is erroneous, provided the cost analysis is accurate and complete, is shown by the authors in the introductory chapter. The completeness of the book may be judged from the chapter-headings, which are as follows: General Economic Principles; Depreciation, Repairs, and Renewals; Buildings; Chimneys; Moving and Installing; Fuel and Coal Handling; Steam Power; Internal-Combustion Engines and Gas-Producers; Hydro-Electric Plants; First Cost and Operating Expenses of Electric Plants; Overhead and Underground Electric Transmission; Wiring; Drives; Compressed Air; Gas Plants; Pumps; Conveyors, Hoists, etc.; Heating, Cooking, Ventilating, Refrigerating; Electric Railways. The book is an excellent reference.

Western Canada Mining Directory. Edited by J. H. Hamilton. Pp. 110, index. Progress Publishing Co., Vancouver, B. C., 1919. For sale by 'Mining and Scientific Press'. Price, $3.

This useful reference comprises a complete directory of metalliferous and coal mines in British Columbia, Alberta, Saskatchewan, Manitoba, and the Yukon, including the names of owners, position, status of development, product, capital, and other data. In condensed form will be found the mining laws of the western provinces and those of the Dominion affecting those regions.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

GASOLINE MINE LOCOMOTIVES

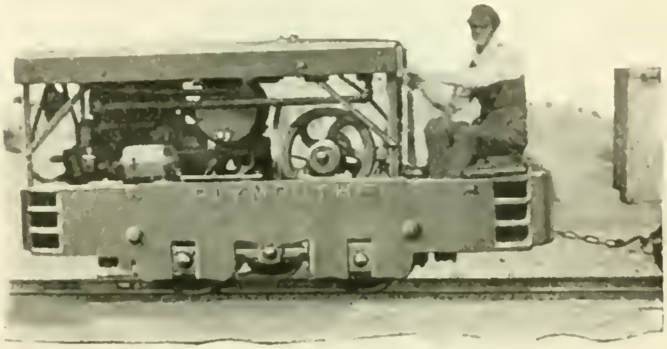
Within the last few years, gasoline locomotives have made considerable headway in mining operations for both surface and underground work.

The J. D. Fate Co., of Plymouth, Ohio, has devoted special attention to the development of a locomotive that is particularly well adapted to the requirements of mines—for both surface and underground use. Every detail has been perfected to make for the maximum of efficiency in construction and operation, as demonstrated by numerous mining companies who have been using Plymouth locomotives under all kinds of conditions for a number of years.

The Plymouth locomotive frame is of one solid casting, affording the best possible foundation for all the working parts, eliminating excessive vibration, and holding the bearings and shafting in correct alignment. Plenty of reinforcing webs have been provided to absorb the shocks and strain. It is built for any gauge of track from 18 to 56½ in. The regular height above the rail is 72 in., but locomotives can be supplied with a minimum height of 52 inches.

The three-ton locomotive is provided with a specially designed 'Continental' motor. A Bosch high-tension magneto is used, and a Stromberg carburetor. Combustion is so complete that no difficulty is experienced from fume in underground work where Plymouth locomotives are employed. A friction drive eliminates the clutch and differential, and the transmission is connected with the engine through an improved type of flexible coupling. Powerful brakes, with a leverage of 6000 lb. and sand-boxes for all four wheels, are provided. The machine is built throughout in a manner to assure a maximum of efficiency with a minimum of trouble. The material and workmanship is of the best. A 3-ton Plymouth gasoline locomotive exerts a 1200-lb. draw-bar pull at five miles per hour, and will haul from 30 to 50-ton load on the level, and an 8 to 10-ton load on a 4% grade. The 6-ton locomotive will handle from 60 to 100-ton load on the level, and 16 to 20-ton load on 5% grades.

The Eighty-Five Mining Co. of Lordsburg, New Mexico, is an example where Plymouth locomotives are used for both surface and underground work. This company has used two of the 3-ton locomotives in connection with its mining operations. The locomotive is operated on an 18-in. gauge track, and is equipped with a self-starter, electric lights, and electric horn. It is handling six 2½-ton cars on the track equipped with 36-lb. rails, and the manager reports that it would easily handle twice as many cars if necessary. The up-keep and cost of operations is reported to be extremely low, in fact, lower than any other locomotive with which the company had any experience. It is used in a 500-ft tunnel, and the manager reports that there has never been any trouble due to gases. The following performance data has been supplied by E. J. Inderrieden, general manager for the Eighty-Five company.



General View of Gasoline Locomotive

"From February 1, 1917, to February 1, 1918, one locomotive hauled 118,859 tons—20-cu. ft. cars—a distance of 1320 ft. and return, or two round trips per mile, or 59,429 car-miles.

Costs

Operating:		
Labor, 990 shifts at $3.50	$3,465	
Material gasoline 3240 gal at 30c	972	
Lubricating oil, 60 gal at 72c	43	
		$4,480
Maintenance:		
Labor, 20 shifts at $5	$100	
20 3	60	
Material	296	
		456
Total cost for 59,429 car-miles		$4,936
Cost per car-mile	$0.083	

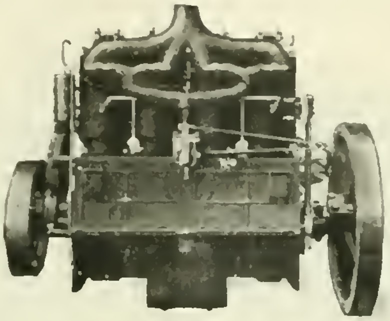
Conversation with drivers, also observation, indicate that

Gasoline Locomotive and Mine-Cars at Eighty-Five Mine, New Mexico the locomotive could easily have handled double the tonnage in the same time, as trips only averaged 7 cars. The locomotive has been an unusually satisfactory and reliable machine and has been operated by inexperienced men. The machine operates in a tunnel without sufficient clearance at switches, which accounts for knocking-off of grease-cups, and, in one case, caps of main roller-bearings. The fibre in the friction-wheel is replaced regularly, but only requires an hour's time."

Details as to construction and operation together with performance data and catalogues (No. 4-Bulletins A, B, G, and H) will be sent upon application by the J. D. Fate Co., Plymouth, Ohio.

CATERPILLAR MOTORS NOW AVAILABLE FOR ANY SERVICE

The Holt Manufacturing Co. of Stockton, California, announces that caterpillar tractor motors are now offered in two sizes—45 and 75 hp.—for stationary work. A number of these motors have been in use for pumping, hoisting, and general stationary work at mines, contracting, and engineering work, but there has been no effort in the past to secure this business—the sales having been entirely unsolicited. These motors have given such splendid service in this sort of work that the Holt company is making a special effort in the stationary field. Tractor service is generally recognized as putting the gasoline motor under the most severe strain, the work always being under heavy load, dust, strain, and heat.



A Caterpillar Motor. These are made in three sizes—45, 55, and 75 hp.—for stationary work. The features are overhead-valve and a four-cylinder distillate-burning engine. They have had four years' war service and many years of agricultural service prior to that.

SEVERE TEST FOR A MOTOR-TRUCK

A remarkable test of a White heavy-duty motor-truck, equipped with double-reduction gear, the latest device of the White Company of Cleveland, Ohio, was reported in San Francisco last week. This machine made the grade (25%) from Union street to Broadway on Fillmore street with a five-ton load. The Fillmore-street hills make one of the steepest grades in the city, and are paved with rough basalt blocks, which makes the traction the poorest possible, according to Leon J. Pinkson. Another feat was the stopping of the truck on the grade and then starting again. This means that the motor and other parts were called upon to start a deadweight of 18,950 lb. on a 25% grade, a thing that will seldom happen in actual service. The gross weight of the loaded truck was 18,950 lb., the weight of the truck 9130 lb. There was also a demonstration of the braking power of the truck. This 10-ton weight was held on the hill, brought to a complete standstill on the slippery grass-covered slope without trouble. Bob Spiegel, factory expert of the White Company, drove the truck. He had tried the machine under all conditions at the factory at Cleveland, but had never tackled anything like this hill before. In order to prove that the gear ratio was standard 13.33 to 1, Spiegel marked a spot on the rear wheel and on the body, then moved the truck with the crank until the wheel made one complete revolution. The wheel turned in 13 revolutions of the crank. Standard Oil 'Red Crown' gasoline was used during this performance.

COMMERCIAL PARAGRAPHS

In Catalogue H-19, the **United Iron Works Co.** of Kansas City, Missouri, describes and illustrates its belt, steam, electric, horse, and hand-operated hoists for mines and works.

The Hydro-Electric Power Commission of Ontario has placed an order with the **Westinghouse Electric & Mfg. Co.** for two 45,000-kva. vertical water-wheel generators of 12,000 volts, 3 phase, 25 cycles, for its Queenstown development. These will be the largest water-wheel generators ever constructed, and indicate that the Commission thinks the present is a good period for construction work.

Mining machinery exported during January was valued at $956,874, plus $106,478 of oil-well appliances. South Africa took $157,788 of the former, followed by Canada with $142,639, Mexico with $112,224, Norway with $67,250, Chile with $64,852, and Australia with 58,181. Of oil-well machinery, Trinidad and Tobago took $28,741, Cuba $17,135, Dominica $15,605, Dutch East Indies $13,299, and Mexico $11,064.

Pumps and pumping machinery exported from the United States during January 1919 were valued at $572,445, according to the Division of Statistics of the U. S. Department of Commerce. Canada took $99,255 of the total, followed by Cuba with $86,088, Argentina with $59,744, Dutch East Indies with $43,993, England with $40,902, Mexico with $33,603, South Africa with $29,067, Japan with $20,811, Brazil with $19,650, and Australia with $14,662.

In its latest 144-page catalogue, the **Hercules Powder Co.** lists, describes, and illustrates the use of its high explosives, blasting and sporting powders, blasting supplies, and chemicals. Throughout the United States, including the large plant at Hercules, California, the works occupy 14,000 acres. Mining men and others will find in this publication a great deal of useful information. The photographs themselves are instructive in depicting the correct way in which to use explosives.

The Sullivan Machinery Co. desires to announce the establishment of a branch sales-office and warehouse for the convenience of its customers and friends in Mexico, at Edificio Oliver No. 3, Mexico City. Joseph F. Bennett, for a number of years sales engineer in Mexico, associated with the El Paso branch of this company, has been placed in charge of the Mexico City office. That office will serve customers and clients in central and southern Mexico, and in that part of the States of Sinaloa, Durango, Coahuila, and Tamaulipas, lying south of the 26th parallel.

The Chicago Pneumatic Tool Co. makes the following announcements: The Detroit office has been moved to 502 Farwell building.——An office and warehouse have been opened at Richards building, Tulsa, Oklahoma, and at El Dorado, Kansas.——The Boston office is now at 182 High street, with F. S. Eggleston in charge.——J. J. Edwards is now manager of the rock-drill sales division, succeeding E Eklund, who has been appointed special representative, and who will leave shortly for Europe.——Fred H. Waldron, formerly Minneapolis representative, has been appointed manager of the pneumatic tool sales division, succeeding J. G. Osgood, resigned. Mr. Waldron's offices are now in the Fisher building, Chicago.——Nelson B. Gatch was recently appointed district manager of sales at Minneapolis, with offices at 301 Metropolitan Bank building.——J. K. Haigh has recently been appointed assistant district manager of sales in San Francisco, at 175 First street.

EDITORIAL

ON another page we publish a portion of a speech on current mining affairs in Mexico and elsewhere, delivered in London by Mr. R. T. Bayliss, who has many friends in this country, particularly in Montana, where he lived for several years as resident manager of the Drumlummon mine, owned by the Montana Mining Company, Ltd., at Marysville. As chairman of the old Exploration Company he occupies a position of importance in London and he uses his influence always on the side of good sense and high ideals of conduct in mining affairs.

COPPER dividends have been generally curtailed, without causing any collapse in the market-value of the shares of the companies producing the metal. This does credit to the good sense of everybody concerned. Even the dispirited return, from Europe, of the representatives of the Copper Export Association does not seem to have taken the heart out of the leaders of the industry; indeed, the sales of copper during March were encouraging rather than otherwise. In the light of subsequent events, if not in that of the facts as known at the time, the request—or command—of the War Industries Board for the continued full-scale production of copper after the signing of the Armistice and until the end of 1918, in order to maintain rates of wages, was a blunder.

SECRETARY LANE, of the Department of the Interior, has been attacked virulently by Mr. James Wickersham, the delegate to Congress from Alaska, in a letter that has been published in the daily press. Judge Wickersham demands the withdrawal of Mr. Lane from the official management of the Government railroad in Alaska, declaring that his administration is a failure caused by "incompetent and petty political partisanship." To any unprejudiced person, it is clear that the attack itself is written for political purposes; it is supported by wild conjectures and unsupported charges so reckless as to merit severe condemnation. The management of the Alaskan railroad may have defects, as is usual in any Government administration of any railroad, but in this case it is evident that Judge Wickersham has exceeded the limits of fair play.

CONVERSATION in the smoking-compartment of the train or steamer today occupies itself chiefly with the penance of prohibition. Wherever men congregate the incidence of prohibition is discussed. Means of evasion supplies a fruitful topic of conversation. What can be done with a raisin or a bit of yeast to elevate the alcoholism of feeble beverages; what home-made distillations will circumvent restrictive legislation; and whether the effort to discipline the citizen will be pushed so far as to prohibit smoking also; these are the topics of an idle hour. Are we to become a nation of law-breakers merely because the prohibitionists have succeeded in 'putting one over us'? We trust not; we believe not. This talk will pass, and the average citizen will accept the edict of constituted authority with as good a grace as he can, realizing that compliance with any particular law is of small importance as compared with obedience to the law, under which alone a democracy can be sustained in peaceful order.

ROMANCE still clings to mining, as is suggested by the story of the Bush mine in the Salmon River district of British Columbia. This prospect was under option, not long ago, to the Consolidated Mining & Smelting Company of Canada, whose engineer condemned it. Last year Mr. R. K. Neill, an experienced miner, happened to be inspecting some other claims in the district on a grubstake from some friends at Fernie, B. C. He found a tunnel showing no particular evidence of rich ore, but on cross-cutting a few feet he cut into a rich lode—no less than 25 feet of ore assaying 100 ounces of silver per ton. This lay alongside the drift, which therefore was practically in the casing of the lode and had just missed striking it! With barely a few hundred feet of development work he opened up ore to the value—it is said—of $11,000,000! This reminds us of the late Captain De Lamar's experience in the Terrible mine, near Silver Cliff, Colorado; he also had only to drive a few short cross-cuts into the wall of the relatively barren vein that the former owners had followed in their drift. Mr. Neill deserves his good luck; he was the man that exposed the placer hoax near Lander, in Wyoming, in which the late Thomas Greenough lost a quarter of a million dollars. Mr. Neill used to be millman for Finch & Campbell, of Spokane, and he found the Kendall mine for them. More power to his pick!

THE letter on 'The Engineer and Public Welfare', appearing in this issue, will be read sympathetically by many of our readers, even if they have not the added interest arising from a personal acquaintance with the writer, Mr. W. F. Staunton. We agree with him that the awakening interest in the welfare of the workers in the mining and metallurgical industries is one of the signs of the times, and the part played by members of our profession in steering that interest into beneficent activity is most gratifying, yet not without a realization of the comparative smallness of the effort and the relative paucity of the results. There is need, as Mr. Staunton insists, for a widespread teaching of the elementary principles of economics, lacking which idealists and visionaries are heard today when they propose schemes just as impossible as that of causing water to flow up-hill without mechanical aid or of making 2 and 2 into 5. We agree with our correspondent that individual freedom in a community is incompatible with lawlessness. For ourselves we would say that an honest policeman is the noblest work of man; to us he symbolizes the one thing that stands between us and the jungle; to us he, as the embodiment of law and order, is more deserving of respect than any king, potentate, and most presidents. The spectacle of the four representatives of the railroad brotherhoods sitting, watch in hand, to threaten the American Congress in a matter of legislation was intolerable; it was just as abominable as a British king sending grenadiers to overawe parliament or a French monarch placing his imperial guard at the doors of the legislative chamber. It was a hold-up, worthy of early days at Bodie or Tombstone. Yes, unionism and collective bargaining have come to stay, just as the collective enterprise of the corporation has become an established means of organizing capital for the purpose of business; but the trade-union should include all the men on the payroll, except the staff, of course; it should not exclude the quiet and more thoughtful men, the very ones most needed to give the right impulse to a legitimate effort at class betterment. In all this work the engineer should play his part; he stands between the predatory elements at both ends of society, the plutocracy and the proletariat; he has the mental training, and, let us hope, the character, fitting him to deal justly with the conflicting elements in a highly industrialized community. We thank Mr. Staunton for his thoughtful letter.

OUR State Legislature has been considering the enactment of a law that will restrict the tipping system by preventing the passing of the tip to a contractor or other employer. The idea is that the gratuity shall be personal and that the system shall not be exploited by employers. We approve of this as a step toward checking a miserable practice. When you redeem your hat for 10 cents at the restaurant your little fee does not go to the receiver, but to somebody back of him or her; somebody who has bought the privilege of preying upon you and the like of you. Under these conditions, the act of tipping, undemocratic as it is, is not justified by being a courtesy or kindness between two persons, it is merely a bit of graft—an imposition to which you succumb because you value your digestion too much to make a protest, either silent or noisy. Indeed the whole tipping system is objectionable, unnecessary, and undemocratic. It is objectionable because it has become a bribe, implicit or understood, paid for service that should be included in the payment made by the purchaser. If you dine at a restaurant, you pay enough to cover good service; if you pay more, the proprietor deducts that much from the waiter's wages. The payer does not even get the benefit of a bribe, for, whether the service be good or bad, the force of custom impels him to leave a tip on the table. It is unnecessary because it has ceased to function as a means of obtaining good service; the victim is committed to the tip as soon as he sits down, and he will not withhold it even if he is badly served. On the Pullman dining-car the colored waiter will not say 'Thank you' unless you give him a tip equal to half the cost of your meal; the tip is merely a part of his regular pay, and, knowing it, you tip him however poor the attention he may have given you. Any traveler will have noted—as we have noted many times—the negro waiter's attitude to ladies giving a small order and likely to give a small tip; the present writer has seen a negro reject a 15-cent tip on a Boston-New York express train when offered by a gentlewoman of the school-teacher type. The system is undemocratic because it is based upon the idea of one man obtaining better service than another; it encourages the gross power of money. In clubs, tipping is prohibited, because it is inconsistent with the social spirit, that is, the desire to consider the rights of others. It is undemocratic because no democrat should ask another to do that which would demean him in his own eyes. If you bribe a man you demean him in your estimation; the fact that the bribe involves the payment of an insignificant amount does not alter the character of the transaction. In Europe tipping may have its place because there people are willing to demean themselves before those socially their superiors; the true democrat knows no superior, and no inferior.

Misinformation

Of late many of us have become keenly aware of difficulty in obtaining the correct information requisite for intelligent opinions. A great crisis in human history is evident; we want to know what is being done to meet it and to guide it for the benefit of our own country first and for that of the world in general; but we have not the data on which to proceed to an intelligent understanding of events, particularly those happening at Paris, where the leaders of the nations are now assembled in solemn conclave. For instance, we had concluded that Mr. Frank H. Simonds, of the New York 'Tribune', was a trustworthy informant; his articles during the War had been, in the main, both accurate and interesting; we read everything of his that we could, believing him to be one of the few writers whose hand was not only directed by talent but disciplined by conscience. Our confidence is now shattered. On April 4 we read in his dispatch dated April 2: "The League of Nations is dead. All chance of a real settlement of European problems is at an end." He proceeded to say that all the smaller nationalities are to be sacrificed to the placation of Germany; France is to be compelled to forego compensation, reparation, and defence against her old enemy "We are sacrificing France on the west to the Germans We are abandoning the small peoples of eastern Europe to the Bolshevists now, and to the Germans hereafter." This was calamitous news, if true; it would have meant eternal dishonor to England and to the United States; it would have stultified President Wilson. There was the clue to Mr. Simonds' aberration: political prejudice so bitter as to prevent him from seeing straight. A man's prejudices are his own, but he has no right to pose as a faithful chronicler and reviewer of current events if he is to surrender his good judgment to narrow partisanship. On April 6 the daily press published another dispatch also dated April 2 from Mr. Simonds, in which he discussed the fate of Poland, Czecho-Slovakia, Jugo-Slavia, and Rumania as if the Peace Conference were able and willing to protect each and all of them from German aggression. "It is seeking," he says, "to combine security with a recognition of the rights of the smaller races." How is the average citizen to reconcile these vagaries of a skilful reporter? Possibly he wrote the dispatch published on April 6 before he wrote the one published on April 4, in which case the public can complain against the stupidity of the editors of the papers in which the dispatches were printed without any explanation. Apart from the contradiction, it is clear that his announcement of the total failure of the Paris Conference was, like that of Mark Twain's death, "greatly exaggerated." At about the same time we learn that the article by Mr. Harold Begbie in the London 'Daily Chronicle' describing an interview with the Kaiser at Amerongen was fiction. On April 3 Mr. William Allen White, in the Hearst papers, asserted that "Lenine has displaced Wilson as director of the conference" at Paris; he suggested that Lenine "may sit actually at the peace table in the flesh, a stronger force than Wilson," and he coupled the name of Senator Lodge with that of the pirate of Petrograd as "the two unwelcome guests at the feast" of Versailles. This is sophomoric rot, yet it will have been read seriously by millions. On the same day the San Francisco 'Chronicle' printed a telegram from a special correspondent whose name we forget—it may have been fictitious—John Henry Tomkins or Charles Thomas Fernitny—saying that the royalist party is showing its head in Germany and there is talk of placing "the Kaiser's brother, Prince Henry of Battenburg" on the throne. This reminds us of a note, in the 'Bulletin', explaining that the Pyramids is a range of mountains between France and Spain, and one in the 'Call' saying that the British had landed a force on the Isle of Lemons. What is our friend the average citizen to do under these circumstances? The anonymous blunders of the daily press are bad enough, but when writers of reputation, men we have learned to respect as trustworthy, like Messrs. Simonds, Begbie, and White, send signed articles exhibiting the crudest partisanship and a plain lack of moral principle, have we not a right to protest? Journalism is a poor thing when it is without conscience and without honor; it is also a highly dangerous instrument in a democracy, in which it plays so large a part as a means of information and education. Why endow universities richly and lavishly by the score and then allow, for example, one non-moral citizen to distribute misinformation and miseducation by means of a dozen newspapers and magazines? Three or four years are spent at the university, thirty or forty years are spent under the teaching of the daily newspaper.

The World's Gold Production

The principal gold producing countries have now published the statistics of last year's production, so that a comparison with 1917 is possible. As our readers are aware, the annual statistics of the world's yield of gold are always incomplete, because most of the minor contributors either publish no figures or announce them two or three years late. Fortunately much the larger part of the world's output comes from the English-speaking countries, which furnish prompt and trustworthy data on the subject. We give a statement compiled from various sources, those that are estimated being marked with an asterisk. For 1916 and 1917 we quote the statistics published by the United States Mint. After making allowance for errors, especially in the figures for Russia and South America, the fact remains that the world's production of gold in 1918 decreased $51,000,000, equivalent to 12%, as compared with 1917, which, in turn, showed a decrease of $31,000,000, equivalent to 7%, as compared with 1916. In two years, therefore, the decline is measured by $82,000,000, or 18%. Revolution, war, and pestilence have played havoc with a basic industry. The full effects of the Mexican revolution are not evident in the figures for the last three years, because that factor came

Africa	1918	1917	1916
*Congo, Madagascar, etc...	$3,200,000	$3,420,000	$3,673,700
Rhodesia	12,862,000	17,245,000	19,232,200
Transvaal	173,479,000	186,503,400	192,182,900
West Africa	6,467,900	7,445,600	7,860,100
Total	$196,008,900	$211,614,000	$222,918,900
Asia:			
*China, etc	4,500,000	5,035,400	4,495,400
*East Indies	2,500,000	2,818,000	3,000,000
India	10,029,000	10,756,800	11,206,500
Japan and Korea	8,500,000	9,006,200	9,308,000
Total	$25,529,000	$27,606,400	$28,009,900
Australasia, total	29,800,000	35,945,400	40,175,800
*Central America, total	3,000,000	3,122,000	3,517,600
Europe:			
*France, etc	1,000,000	1,717,000	2,019,900
*Russia and Siberia	10,000,000	18,000,000	22,500,000
Total	$11,000,000	$19,717,000	$24,519,900
North America:			
Canada	$14,687,000	$15,200,000	$19,235,000
*Mexico	10,000,000	9,000,000	7,690,700
United States	68,493,500	83,750,700	92,590,300
Total	$93,180,500	$107,950,700	$119,516,000
*South America, total	$14,000,000	$14,634,000	$15,188,400
Grand total	$372,518,400	$423,590,200	$454,176,500

into play after 1911, when gold to the value of $31,000,000 was produced. The El Oro district used to contribute a quarter of this handsome total, but in recent years the gold-mining industry of Mexico has been stagnant, with flickering signs of revival during 1918. The revolution in Russia is accountable for the big decrease since 1916, the figures for last year being a guess. The Lenskoie, Orsk, and other important mines were not much affected by the Bolshevist outbreak. A great deal of gold is stolen from the Siberian mines and is taken into China, but whether minted there or in Russia, it becomes part of the world's stock of the standard metal. In Australasia the decline has been almost continuous during the last ten years; in 1903 the output was worth $89,206,000, and in that year Western Australia alone yielded $41,296,000. In the United States the peak of production was reached in 1915, when the output was worth $101,037,700. That was also the year of the world's maximum output, thanks largely to the Transvaal. The final figures for the United States are likely to be less than the latest estimate. The European production is small but interesting, because it comes from the oldest mining districts in the world, from Gaul, Dacia, and the Ural, chiefly the last. The War, of course, checked operations in these parts; it affected the production of gold everywhere, by decreasing the supply of labor, by increasing the cost of supplies, and by hindering the erection of plant. In the last quarter of 1918 the epidemic of influenza, decimated the labor supply, on the Rand especially, but in other districts as well. Besides these abnormal interruptions to gold mining we must reckon with the gradual impoverishment of mines, particularly in Alaska, Colorado, and Western Australia, but also in the Yukon, Victoria, West Africa, and, more especially, the Rand, which is still much the most productive of the world's goldfields, yielding 46% of the grand total. In truth, it is surprising, considering all the adverse conditions, that the world's output of gold has not suffered more, and this is due to the continued vitality of the industry, although no great discoveries have been made in the last two or three years, nothing comparable with those of Cripple Creek in 1893, of Kalgoorlie in 1896, of the Yukon in 1898, or of Goldfield in 1906. Nevertheless, single orebodies, enriching individual mines, have been discovered in many localities, and important finds and developments have been made, for example, in the East Rand, British Columbia, Ontario, Nevada, Arizona, Mexico, and Korea. The world produced less gold in 1918 than in any year since 1904, but we believe that the signs are propitious for an improvement. Of the total output in 1918, 18.4% came from the United States and 66% from the British dominions, so that over 84% came from the English-speaking countries. Another method of segregation may be based upon the alignment of the nations in the Great War. Mr. Hennen Jennings showed that in 1913 the Allies produced 91.3%, the Neutrals 8.1%, and the Central Powers only 0.6%. The comparison is complicated now by Russia's dubious standing, but it is noteworthy that the Germanic countries now depend almost entirely on Transylvania for their domestic gold, and that amounts to barely 0.5% of the world's production.

The War Minerals Relief Act

Rumor says that the Department of the Interior is likely to interpret the War Minerals Relief law to mean that claimants for compensation must demonstrate personal solicitation by Government agencies as a condition precedent to establishing a valid claim. It is a fact that an amendment to the Bill was offered in Congress providing for just that limitation, but it was insisted by the sponsors of the relief measure that the result would be to exclude a large number of honest claims, because the requests of the Government for the intensive production of war minerals were general, and did not constitute personal appeals. The limitation was removed, and the debates in Congress, as reported in the Congressional Record, will show that this restriction was duly considered and rejected. Therefore such an interpretation of the law is not in accord with the terms of the Act and suggests a breach of good faith such as calls for strong reprobation. It is said, by one not without authority, that these war demands for production were no different in principle from notices calling attention to opportunities for production to meet a market demand at any time, even before the War; but to this we demur unhesitatingly. The Department will incur just criticism unless it construes the Act liberally and in accord with its intent. If such a narrow interpretation is given to it, the question will certainly come before the courts and provoke bitter litigation. Although the Act affirms that the decision of the Secretary shall be conclusive and final, that proviso relates to his adjudication of "adjustments and payments in each case"; it has nothing to do with the interpretation of the Act, which is open to review in the courts, since such a right is secured to the people by the Constitution; it is not inhibited in this Act and cannot be inhibited by any act of Congress. The Act itself places a limitation upon the finality of the Secretary's decision in the matter, since the Government is specifically not barred from a review of any case arising under this law by any agency of the Government or by a Congressional committee. The rights of claimants are safeguarded in this measure and it will be most unfortunate if litigation is invited by a wrong interpretation of the Act. The one sharp limitation is that any claim to have standing before the Department must be filed within three months, that is, before June 2. On page 407 of our issue of March 22 we published the regulations and on page 445 of our issue of April 5 we stated that the requisite questionnaires can be obtained by writing to the War Minerals Relief Commission, whose address is Suite 2131, Department of the Interior building, Washington, D. C. The commission appointed to take charge of the payments due under the Act are Senator J. F. Shafroth of Colorado, Mr. Philip N. Moore of St. Louis, and Dr. M. D. Foster, formerly Representative from Illinois.

DISCUSSION

Flotation Patents

The Editor:

Sir—Sunday and waiting for a train is my excuse for making you my victim. I have just finished reading your interesting article in regard to the Wolf patent in your issue of the 22nd instant. Twenty five years of experience as a lawyer before the Federal Courts have taught me not to assume that the Court is wholly devoid of intelligence, and that same experience leads me to the conclusion that little is to be expected from the Butte & Superior case. The courts are bound by the law, which includes the rules of practice. Such law, and it is the only one that can be safely admitted, requires the Court to act solely "upon the record before it"—and therefore the Court is not to be blamed for a decision based upon partial or erroneous information, if that is the record before it.

In the famous Hyde case, the "three errors" which constitute the support of the throne now graced by our Minerals Separation friends, namely, "agitation greater than," "froth so different from," and the "critical" quantity of oil were the points in controversy. The Butte & Superior was operating, or at least trying the case, on the theory that this 'trinity' was essential. Had the Court been shown that the 'agitation' and 'permanent froth' were non-essentials, and then had been invited to focus its attention on the alleged 'critical' quantity of oil, and had been advised that Wolf, Elmore, and others had patents covering froth produced by the 'critical' quantity of oil, the decision rendered might have been less obscure.

Coming back to the present appeal by the Minerals Separation v. Butte & Superior: as I recall the facts published by your magazine at the time, the appellee is bound by the 'law' as announced in the Hyde case—the parties being the same—and it admits that it used the sacred 'trinity', *plus*—that "plus" being oil above the 'critical' point, by reason of which (this plus) they asked to be held not to be violators of the rights of the Minerals Separation company.

Said record shows that two pounds of the 'emulsifying' and 'gathering' oils would do the work, and no good reason or excuse was given for the addition of 18 pounds more—and it can reasonably be said that such additional oil was less valuable than so much water, and that its presence was mere camouflage to get away from the 'critical' point in the Hyde case—however erroneous—the law as between parties. Now—giving the Court credit for having some intelligence and reasoning ability—what is it going to say? Taking the Butte & Superior position: The soused gentleman might say, "Yes, I get drunk on two drinks, but in this instance I took twenty; I, therefore, am not drunk."

Let a case be brought where the mining company does not use agitation, does not make a 'different' froth, and follows the methods within the claims of Wolf and Elmore, when the parties are not bound by 'the law of the case,' but are new-comers before the Court—not bound by the Hyde case—and give the Court a chance to hear and decide the matter on its merits, and you may get something understandable at least.

A. L. BEARDSLEY.

En Route, March 23.

The Engineer and Public Welfare

The Editor:

Sir—One of the striking lessons of the War has been a realization of the increasing dependence of civilization upon the engineer. Engineering genius, already appreciated as the mainspring of material progress, is seen also to have been absolutely necessary to the preservation of our ideals of democracy in the world. It has become apparent that the training in clear exact thought coming from technical education, constant contact and familiarity with the fundamental laws of Nature, and the diverse nature of engineering activities in all parts of the world, have given to the engineer a broad outlook upon the problems of society that makes his judgment particularly valuabe in questions of social organization. In the vital new problems everywhere pressing for solution, not alone in a physical sense but in the broad, economic, and humanitarian principles also involved, it is a welcome fact that the engineer is becoming increasingly active. The drift of thought toward social problems and the helpful spirit shown by giving such thought publicity in recent public utterances is reassuring; and engineers who, like J. Parke Channing in 'Man Power'; J. F. Kemp in 'The Human Side of Mining Engineering'; and T. A. Rickard in numerous editorials, have done a service of the greatest value. To these, we could all add the titles of many more articles brimming with uplifting thoughts on the great problems now before the world, showing that engineers as well as others must take an increasingly active part, and quickly, in the reconstruction and operation of the social machine if our country is to maintain its influential place in the world; perhaps one could go further and say, if it is to avoid disaster from trying working-scale experiments which an elementary knowledge of history and economics should prevent. But we listen, or read and agree, just as we do when we go to church, without doing anything practical, and it is feared that many of us slide back into our habitual grooves, leaving 'George' to do the rest; and yet we have before us problems compared with which going to war may prove to have been easy. There will be no flags, bands, and uniforms, as stimuli, nor the exuberant appropriation of billions to accomplish results regardless of cost. Economic laws, so lately suspended, will again be in full operation. Efficiency of labor, which, owing to the prodigious market that has existed, and the necessity of getting things quickly regardless of cost, has declined alarmingly here, but has, on the other hand, increased abroad; a production per man of ten times the pre-war rate having been reached in some lines according to eminent authority. A severe jolt to our complacent boast of superiority seems unavoidable when normal competition returns.

What, in a practical way, are we going to do about it? What is the solution of the problem? It is education; but not that sort that comes to the mind of the school-trained man when the word is used; not a vision of books and apparatus, but rather a knowledge of those simple, homely, historic, economic, ethic truths that man in his painful upward progress has again and again verified by the ghastly failure of experiments which this generation seems now about to repeat. Education is the key-note of Secretary Lane's 'Americanization'; but even in that masterly appeal one can wish for more emphasis on the elemental principles. The English language should be first, of course, for those ignorant of it, but after that, as between imparting the power given by the 'three R's', to be exercised in absorbing poisonous misinformation from the yellow press and reckless propaganda in general, and a knowledge of how to think clearly on the problems of everyday life, the latter is preferable; but there is no good reason for not having both.

It is a common experience that not many, even of the fairly enlightened people one meets, can give a clear and logical explanation of capital; what it really is, its origin, its benefit to all, laborers included; and why it is necessary for any material progress whether under individualism, socialism, or any other ism. So, in regard to what is possible in the long run in the payment of wages; that the market value of the things produced sets an absolute limit to them; that no legislation or strikes can change this condition, notwithstanding that an occasional professor arises to testify that the basis of minimum wages should be made by law the cost of a comfortable living, a condition we would surely all welcome, if true. But the place man is making for himself in the universe is an artificial one, and is maintained only by his successful struggle to re-direct forces tending otherwise, and it is success in this struggle, and consciousness of ability to succeed, that gives man's intelligence its god-like potentiality, that develops his strength, and supports the hope of progress. So the elementary idea should be taught that the things worth having, even those altruistic in character, are only the rewards of effort of muscle and of brain, and not within the power of legislatures or unions to bestow.

The conception of freedom, too, needs clarifying. The more we hear of it lately the less there seems to be. There is none when the laws guaranteeing a man protection from violence in the pursuit of his ordinary vocations are a dead letter, and when his head may be broken with impunity or approval if he fails to join a particular organization, which he does not want to join, for possibly very good reasons of his own. What unjust strike could succeed if unlawful violence were made impossible? The spectacle of four men forcing the American Congress to pass a law under direct threat of starvation to innocent millions by paralyzing the railroads, is not an indication of freedom regardless of the merits of the law. The unions and collective bargaining have come to stay; their justification is their undoubted improvement in the workers' economic status. As their potentiality for good is tremendous, so it may be also for harm, to the workers themselves and to society in general. The result of their unrestrained development needs no prediction. Fighting the abuse of their advancing arbitrary power and its inevitable train of needlessly repeated experimentation by the exercise of another arbitrary power is unintelligent, and enlightenment by education in the fundamentals of economics and ethics is the only way in which these agencies can be dealt with effectively; that is, by preserving the good and eliminating the evil. It is not too much to hope that some day membership in good standing in a trade union will be a guaranty of ability and integrity instead of a danger signal.

The practical wisdom (aside from any other cause) of a system of ethics should be made plain, and the fact that theists of all kinds, agnostics, atheists, even pagans, and probably Germans now, appreciate, and, in their hearts and minds, really believe in the essential truth of the broad principles of morality taught by Christ, and that the most rapid development of the human race, not alone in material things but also in the average of individual well-being and happiness, is coincident with the Christian era. A part at least of the unrest at the bottom of much of the present turmoil is doubtless due to the fading away of old religious beliefs without the substitution of other guides. With the disappearance of the blind acceptance of constituted authority, physical and moral, which we have seen everywhere, has come the dawn of an attempt to analyze the situation without the guide of historical or economic knowledge. We can imagine a new Russian thinking: "I find myself here on this planet wholly without my consent. I see others around me with far more of the things that might make life pleasant; indeed the sole occupation of many seems to be to devise new means of enjoyment, while I slave on a pittance. To be sure, they say that rules have been made permitting this condition, but I did not agree to these rules, and it even appears that they were made by people most of whom are now dead, and that they are perpetuated and revised by a small minority of those now here, the others not bothering to express themselves one way or another. I decline to recognize these rules, and I am going to get what I want in any way I can. The game has evidently been 'rigged' by a lot of people who happened to be here first, and I don't propose to stand for it." Perhaps not many have formulated the proposition in a manner so raw as this, but there is little doubt of the growth of some such feeling, and nothing but education can combat it. Fortunately, the kind of education needed is elementary in the extreme and not of a kind requiring much time or study. We can all be teachers in such a school; but in this as in other things in this world, the same old competitive system on which everything is planned is still in operation; and we have formidable competitors. Since the growth of conscious power from organization, which has come largely within the life-time of many of us, we have been forcibly reminded that great mental ability is quite compatible with moral obliquity, and that such mental ability can be hired for unworthy purposes. Many of the organizations we shall have to deal with are possessed of abundant financial means, and with their great numerical memberships can, and do, accumulate formidable sums from trifling individual payments, which sums constitute an irresistible temptation to brilliant but unscrupulous minds. Also, we have the venal yellow press, where control by one vicious mind permits feeding mental poison to millions. These are the worms at the root. Many people have acquired their whole education among the branches and twigs of the tree of knowledge, and know nothing about the roots and the trunk at which a busy little worm may be conducting operations, the effects of which they see among the leaves and try to combat with futile local treatment. J. R. Finlay has the happy faculty of going to the foundation of things and building thereon structures in which one cannot help feeling confidence. His 'Reorganization not Reconstruction' is a delight to one who believes in beginning at the beginning, in setting up as he does a row of axioms and building his argument firmly thereon. It is something like that which the enlightened people of the world must do to steady the structure of civilization. We must get down to the foundations and make them secure; patching the cracks afterward. Fixing foundations is pre-eminently an engineering job. It must be done by enlightening propaganda, elementary education, pounded into every crack and crevice that can be found, and, judging by the startling manifestations daily witnessed here, there, and everywhere throughout the world, there is no time to lose.

In olden times, ideas traveled slowly but today they are flashed to every corner of the world. That good ones can be spread quickly and that they will take effect with marvelous results, is shown by looking back at Mr. Hoover's work in food conservation, where a few simple, vital facts, spread like wildfire, found ready acceptance, accomplished the apparently impossible, and prevented the loss of the War, already privately conceded by Lord Rhondda on account of the supposed inevitable failure of the food supply. Something like that can be done in back firing against this social conflagration. This country is full of organizations. There are clubs and societies by the thousand, for this, that, and the other thing, but most of them in eager search for a really interesting object, notwithstanding their titles. They overlap and their members touch elbows constantly. They are mostly composed of rather enlightened people, employers of others in large and small degree, in the aggregate very numerous, their members move about so as to increase the points of contact to a degree that would make the spreading of propaganda well nigh perfect. They constitute a possible means of combating social heresies that could be of great value. At a recent meeting of one of the national engineering societies a letter from one of the members was read covering suggestions as to what subjects of discussion might assist in the necessary readjustments, and among his suggestions is "educating the workmen in economics." He said he believed that the society "should devote a large part of its discussions to the ascertainment of the best means of educating men along these and similar lines." This suggestion should be acted upon by all of us, but without waiting for discussion we should begin forthwith to preach the doctrines of social sanity as taught by history and common sense wherever an audience is found, with an eye particularly to getting similar missionary work done by the membership of such clubs and societies as we belong to, so that a beginning may be made, somewhat in chain-letter fashion, in furthering this important work, the most important by far before the world today. Let discussion follow by all means, and it is to be hoped that it will result in formulating something like a set of Mr. Finlay's axioms, with a superstructure of simple but definite conclusions on the vital economic questions, which can be used as propaganda in the way suggested or in some better way that may develop.

W. F. STAUNTON.

Los Angeles, California, February 12.

Cost of Mining Silver

The La Rose mine at Cobalt, Ontario, yielded 4,092,667 oz. of silver in 1911, but only 276,131 oz. in 1918, making a total of 24,484,053 oz. since 1907. Last year the mill treated 36,612 tons of ore, averaging 7.71 oz. per ton. The average price received was 99.83 cents per ounce, and the cost was 87.17 cents, details of which follow:

	Cents per oz.
Mine operation	47.61
Milling	32.49
Marketing	10.44
Depreciation	2.19
General	2.13
Total	94.86
Less sundry income	7.69
Net cost	87.17

The Prevention of Misfires

By GRANT H. TOD

From time to time articles appear in various technical journals concerning the causes of misfires, and many writers offer novel cure-alls for this old and annoying feature of blasting. The bulk of the blame is usually attributed to defective material, without serious thought being given to the careful selection, preparation, and use of explosives and accessories, and other important contributing factors. The cost of mining being a matter of the highest importance it appears well to investigate this subject from a practical standpoint, attempting to show the underlying causes and offering for approval some remedies that have already proved their value.

Unsuitable material is likely to be selected. Powders are used whose composition is entirely unsuited for the work. Caps too low in strength are chosen, and fuse is purchased for its price, without regard to its construction. A simple remedy for such conditions would be a letter to your powder company, giving an accurate description of the work to be performed. This would elicit reliable information, and, if circumstances warranted, a visit from one of their competent engineers.

All explosives demand dry storage. This means that, with few exceptions, underground storage is undesirable. It has been proved that powder, caps, or fuse sent into a mine a short time before use give the best results. The inconvenience and slight loss of time occasioned by using the haulage-motor or cage for this purpose is more than compensated in the decreased number of missed holes.

Probably the most fruitful source of misfires is the careless preparation of cap and fuse. The base of this trouble is at the mine or quarry, not at the factory. The remedy is as follows: Avoid any chance for wet fuse ends by cutting off a quarter of an inch from all fuse that has been exposed to air for any length of time. Cut the fuse squarely across, with a clean sharp instrument, insert it into the barrel of the cap until it comes in light contact with the fulminate, and, holding it firmly in this position, crimp with a broad-jawed crimper. It is well to remember that an unfilled air-space in a cap-barrel, after the fuse has been inserted, is an invitation for trouble. Of all operations where results justify a little extra care, none exceeds in importance the correct preparation of cap and fuse when forming them into a primer.

With electric exploders the most common cause of misfires is the practice of putting the exploder into the side of a cartridge and securing it by a half-hitch. This practice has a tendency to chafe the wire insulation and leave the wires in short circuit, or allowing water to get in and complete the short circuit. The rough handling of the tamping-bar will, at times, crush the sulphur plug and let water get to the cap.

The use of the following unsuitable materials to exclude water from a capped fuse should be avoided: axle-grease, engine-compound, oils of any kind, cable-dressing, electrical varnishes and paints containing solvents of the fuse-varnish. In place of these use P. & B. roofing paint, tar, paraffin-wax, or one of the preparations specially put on the market, by fuse manufacturers for this purpose.

Atmospheric conditions and systems of ventilation have a decided bearing on the subject. Where humidity is great and mine currents are sluggish there is a marked increase in missed holes where powder, caps, or fuse are stored in underground magazines or where these materials are allowed to remain in open containers, in the mine, for any length of time. A remedy is to cut and cap all the fuse at a central station, on the surface, and to send underground only sufficient quantities of capped fuse to last 72 hours, and likewise to limit the powder supply to practically immediate needs.

Exposed fuse-ends protruding from bore-holes must be protected from flying rock when blasting. This can be accomplished by coiling the fuse-end in the collar of the hole in such a manner that only enough remains in sight to ensure an easy 'spit'.

Where mine-pumps have to be lined with bronze to resist acid water the mine superintendent should realize that all fuse is not resistant to acid. It is suggested that a good tape-covered fuse will prevent many missed holes.

Failure to supply the miners with proper appliances to 'spit' the fuse is another cause of missed holes. Carbide lamps, now in common use, hot irons, and a newly marketed device, named the 'lead-spitter' are efficient. The lead-spitter is by a long way the best for the reason that water in any quantity cannot quench it.

The improper spacing of holes drilled in close proximity causes many a missed hole. Investigation underground disclosed that in wet ground the holes most frequently missing were 'lifters' in drifts and cross-cuts and in corner holes in shafts and winzes. It has been demonstrated that the reason for this was the small amount of ground left. As such holes are wet in nearly every instance it was found that the bursting of the hole immediately next them drove the water laterally through the fuse or delay-exploder in the hole that mis-fired, saturating them to a point that they could not perform their function of carrying fire to the cap. The remedy for this kind of misfires is closer attention to the spacing of the holes. The introduction of drills using water, in mines where the ground would be considered dry, necessitates precautions considered sensible in wet ground.

A cause of misfires not generally recognized is the sweep of air returning during blasting operations. This causes portions of the powder-charge in untamped holes to be thrown from the hole, including the primers. In wet holes the force of the returning air has, on occasion, been found great enough to displace the sulphur plug in an exploder and to saturate the powder and fuse with water, thereby destroying their usefulness.

Rough sharp rock when used for tamping may lead to misfires, and in instances where a steel-drill or a bar is used as a tamping-rod the hazard is likewise increased.

The League of Nations and the Covenant

By C. IRVING WRIGHT

The 'covenant' of the Paris Conference is not a treaty; if executed, it will constitute a new government of the world. Neither the President nor the Senate, nor both combined, have been given authority to represent the States, or the people of the United States, in the formation of a new government.

The attempt is made to persuade us that there is no real difference between the covenant and a treaty; it is said that many treaties impair, to a certain extent, the national independence of action, the sovereignty, of the high contracting parties. The analogy is specious; it captures the imagination even of intelligent men; but it is not true. Treaties, far from impairing sovereignty, involve the exercise of the highest right and power of a sovereign, the right and power to deal freely and on terms of equality with other sovereigns. Treaties are gentlemen's agreements, and derive their obligation, according to the universal understanding, solely from interest and good faith; in them is to be found no other compulsion, and they have no further sanction. Their terms are mutually interpreted by the parties and are performed only in accordance with the mutual interpretation; even when they are put to arbitration the award that may be made is enforceable only through free will and consent. No independent nation, it may be surely asserted, has ever seen in any treaty, executed by it, an obligation to submit its neck to the yoke. The very essence of sovereignty is unaccountability to a superior and immunity from control.

It is easy to determine whether the covenant is a treaty, or whether it constitutes a government to which the nations signing it will subject themselves. No nation in history has ever been troubled by difficulties of logic in distinguishing between the freedom that accompanies treaties and the control that follows subjection. With regard to this real and vital distinction, the common sense of the country, despite the propagandists, the gynagogues, and the special pleaders, is beginning to assert itself. Patriots like Mr. Taft, even though at first they may have misapprehended the nature of the document, are now calling for amendment. There is firm ground for faith that the truth can be made to appear before it is too late.

To reconcile the covenant with the Constitution, Mr. Taft is compelled to argue that future Congresses would still have authority to give it an American interpretation and to disregard any conflicting construction put upon it by the League. He says, however, that the exercise of this authority would be gravely dishonorable, and cases can easily be conceived of American interpretation and action that, under Art. XVI, would "*ipso facto* be deemed * * * an act of war against all the other members of the League." The foundations of our dishonor are being deeply laid, for in a war arising out of insistence upon our own views, we would be ostracized, outlawed, and treated, like the Hun, as having shocked the moral sense of mankind.

Already the differences of interpretation are bitter and momentous. Mr. Taft will not be the official interpreter of the instrument; nor will eminent Senators; nor the Senate; nor Congress; nor, indeed, the whole People. The document, once executed, creates irresponsible and uncontrollable super-national tribunals, which alone will have authority to determine its scope and meaning, and which are provided with well-nigh universal power to enforce decisions.

To attempt to forecast the decisions that will be made is futile, for the human mind is quite incapable of foreseeing the cases that will arise during even the next decade. We know, however, that the covenant, like other political instruments, will be construed more broadly year by year. This law, that power grows by exercise, is recognized by the official organ of the American Federation of Labor, which says that the League will inevitably grow in power, and will tend to treat every question from the international aspect, and that in this process national forces, such as labor and individual lives, are bound to be affected by its decisions. Indeed, as Mr. Wilson accurately says, "There is no subject that may touch the peace of the world that is exempt from inquiry and discussion."

"Inquiry and discussion?" Yes, and effectual action, too. By Art. XI, "the high contracting parties reserve the right to take *any* action that may be deemed wise and effectual to safeguard the peace of nations." "Any action," means action legislative, judicial, and executive; action without restraint or limit. Who would attempt to enumerate the categories of subjects which "any" action may rationally be deemed to include?

So, too, examine Art. XX by which the nations covenant "to endeavor to secure and maintain fair and humane conditions of labor for men, women, and children both in their own countries and in all countries to which their commercial and industrial relations extend." Equal wages throughout the world may be the League's interpretation of "fair" conditions of labor. Already the Commission on International Labor Legislation has issued a report, which, as the 'Christian Science Monitor' says (March 5), "is of a far-reaching nature and, if adopted by the Conference, will change, as is already being remarked, the whole aspect not only of the labor problem in the countries of the world, but will also relieve the export trade difficulties, which are dangerously and continually enhanced by higher wage and shorter bour demands." A code of labor legislation is proposed, with punishable offenses. Mr. Taft's argument that America has the right, under the covenant, to prohibit or to regulate Chinese or Japanese immigration, to discriminate against one nation and in favor of others, to insult the dignity and self-respect of a powerful race, is punctured, bubble that it is, by the provision in that code that no nation shall prohibit immigration or emigration except temporarily in periods of economic depression or for the protection of public health. It matters not what the Council may now do; the power to consider and decide now is the power to consider and decide otherwise in the future. Immigration is not, therefore, a "domestic" affair as Mr. Taft supposes; and the League is proving its power by acting.

What, then, is "domestic"? The tariff?

The super-national tribunal may decide, and there are many respectable thinkers in Europe now propagating the conviction that a chief cause of war is to be found in economic barriers. In Mr. Wilson's view, therefore, the import duties of the respective nations are open to "inquiry and discussion," and under Art. XI they are a proper subject of "effectual action." Free trade throughout the world may be decreed and enforced; and, since it is universally established that the power to accomplish a result carries with it all incidental powers deemed necessary or expedient as means to the end, the League may order destroyed all books that preach the peace-disturbing doctrine of protection; moreover, the arrest and imprisonment of men who speak or write in opposition to the edict may be commanded. This is only an example. Let there be no mistake, the powers that the League determines to exercise, it can, and will, in its own good time, exercise to the full; no restraints, verbal or of principle, are provided.

Eminent students of political science, and of the American Constitution, construe the covenant and hold that to ratify it, as it is now framed, would be to violate the most fundamental provisions of our institutions and organic law. Thus, it would not bind the United States (Geofroy v. Riggs, 133 U. S., 258). On the other hand, many of those who favor a league regardless of all things except their passionate hope that war will thereupon vanish from the earth, reply by themselves putting a contrary construction upon the instrument, or by saying that they do not think the fear is well-founded. With all respect to the eminence of the controversialists, it is submitted that the question of the constitutionality of the covenant probes much deeper than guesses as to what the document may ultimately be determined to mean. If its constitutionality depends upon the interpretation that may be given it by the League, then the President and the Senate cannot know whether they are exceeding their powers until after it has been ratified and has been interpreted in practice.

The very reason why the covenant is unconstitutional beyond the possibility of rational controversy is that it attempts to bind all succeeding Presidents, Senates, and Congresses, in a word, the United States, to accept whatever interpretation may be put upon it by a super-national tribunal constituted with power to enforce its decrees.

The League may not do one or another of a multitude of things, or the League may now, for strategic reasons, decide to do precisely what it will tomorrow undo. What will be done lies in the womb of fate, and, in any event, is quite beside the question. The loss of sovereignty of the United States, if this covenant be ratified, consists in our having parted with the effective right and power ourselves to resolve for ourselves from time to time, the vital problems that will present themselves for consideration throughout the future. The involved and subtle arguments of special pleaders are not needed to decide this simple question, which can easily be answered by any man who has the natural faculty of reason and who has learned to distinguish fact from fancy. For him there can be no doubt that by the covenant the United States would be parted from its sovereignty, and would henceforth, until a greater war, be bound a satellite of Europe, governed by every pull and push of her interests, and without rightful power to pursue an independent orbit.

Neither the American people, nor the States of the Union, have constituted any body, or delegated any authority, to barter or to give away the national independence. The President has no power to initiate, nor the Senate to ratify, any negotiations of such character. Insofar as the covenant conflicts with specific provisions thereof, the Constitution, if it be deemed expedient, may be amended by the processes provided to that end, but insofar as it is attempted to institute a new government, to create a new sovereign, there is no lawful power in three-quarters of the States, nor in nine-tenths of the States, to deprive an objecting State of its right to be represented in all matters concerning foreign relations or within the jurisdiction of the Senate under the present system. A revolution by force, a *coup d'etat*, may, of course, be effected, if at this juncture, and with the example of Europe before us, it is thought wise to unloose the now orderly forces of American society. But if regard be had to the organic development, and the continuity in history of our institutions, the League of Nations, as it is now framed, or if framed in anything like its present form, can be constituted only by the consent of every State of the Union. (See Geofroy v. Riggs, 133 U. S. 258; Fort Leavenworth R. R. Co. v. Lowe, 114 U. S. 525.) Is it proposed that coercion be employed and that our compact of union be disregarded?

Why, indeed, should New York State not have representation equal to that of Canada; or California equal to that of New Zealand? Unlike the British Dominions and Colonies, which are not now represented in foreign relations, our States, through their Senators, participate directly in foreign affairs; for our Government is federal. Not only in a legal and an historic, but also in a present, and a very real and practical sense, the States retain the right and power to make known and protect their interests, and they cannot be drawn into a new government against their will: neither can the Federal government abdicate its functions or secede.

The United States is of great territorial extent, and its various divisions have important differences of interest. Is Pennsylvania not specially interested in tariffs? Is California not vitally affected by immigration? On what theory can they be denied a hearing, while Canada, New Zealand, New South Wales, Australia, and South Africa gain important rights of representation not theirs before? Mr. Wilson says it is a wonderful thing, the trust that Europe has in America. Why, then, deny us the representation that is commensurate with our population, our wealth, and our extent of territory, and that is required by the structure of the institutions which we have developed in history?

To make "the supreme sacrifice" of our liberties, neither President nor Senate have mandate or authority; they were not elected with that in mind, nor were their offices created with such power. Already it is being propagated by chancelleries of Europe that the treaty of peace would have contained quite different terms had it not been thought that America would ratify the covenant. To this the answer is plain: Let the nations that deal with delegates look to their credentials, and let the words and acts of constituted authorities be compared with the Constitution that created them.

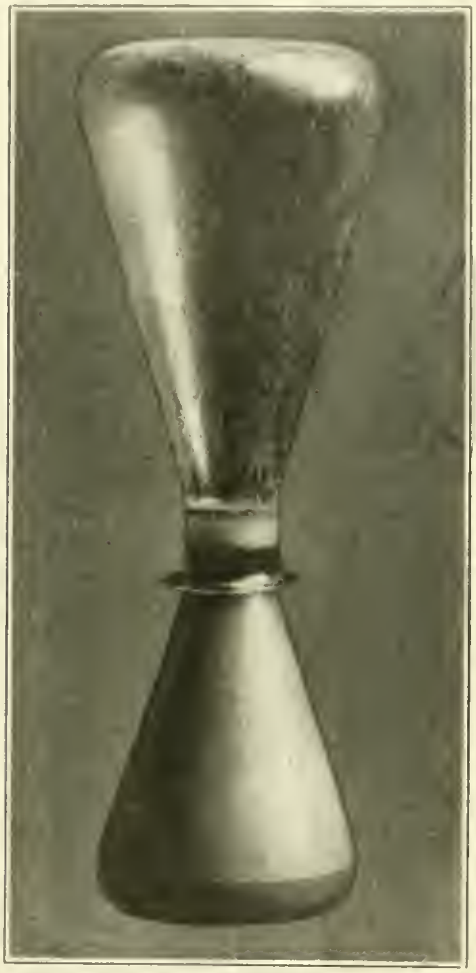
No country will be more prompt to fulfill obligations and to make sacrifices under the covenant than the United States, provided it shall freely and through orderly processes pledge its fealty. But our Sovereign does not reveal himself by intuition to those who feel inspired. He does not express himself by 'voices in the air' that cry out the changing emotions of the shifting mass. Only by diligent searching can his will be ascertained. We are hysterical—he is calm. We are deceived by propaganda—he sees reality. We love our friends and hate our enemies—he knows principles without respect of person. In a word, he is essentially wise and we are essentially foolish. This Sovereign is no other than our common and permanent right mind. Certainly, we cannot, at a given moment of history, completely discover him, but we can make the best humanly possible attempt. We can call into a Constitutional Assembly, to deal with the supreme problems that confront us, the best persons our common action can find, not merely in the Nation, but, as well, by States; for thus the regional divergences of interest will be reconciled, and the law of the structure of our institutions be fulfilled.

MANGANESE DEPOSITS are being worked near the town of San Antonio, Province of Pichincha, Ecuador. The principal orebody is a blanket deposit 3 to 9 ft. thick. The ore resembles gravel in appearance, and assays 46.36% Mn, with a little copper and phosphorus. Silica is only 6.4%. The altitude of the property is 7874 ft., and the district is wholly volcanic, partly covered by sand. Native laborers receive from 20 to 50 cents per 10-hour day. Quito is 28 miles distant. Mule carriage to rail at that place is 68 cents per 220 pounds.

A Device for Flotation Experiments

By WILL H COGHILL

[*]In flotation experiments it is desirable to have a small hand-operated device correlating with the larger experimental and commercial machines. This phase of flotation has not been sufficiently developed. It is my purpose to describe a device which is intended to fill this gap.



FLASKS USED FOR FLOTATION EXPERIMENTS

Success in designing a machine depends upon the principles selected to govern its detail. The selection of this device was based upon the two factors of pulp-density and ratio of solid to frothing surface. The importance of these factors can best be emphasized by quoting from Del Mar.[‡]

"Under manipulation may be included the shape or form of the collecting-chamber of the flotation machine, for the cells in any flotation system are used for two purposes, either to float a dirty concentrate, which must be cleaned before marketing, or to float a finished concentrate, which is ready for shipment. In the former case the collecting chamber of the machine should favor a quick discharge, that is, there should be a narrower chamber, but when we require a finished product the box must be sufficiently wide to allow the settlement of occluded waste or gangue. Manufacturers of flotation machines miss this point and therefore the same machine is often used for roughing and for cleaning, while the two operations require entirely different manipulation. This important structural feature in the flotation-chamber may make the difference between success and failure, for not only must a concentrate be produced, but it must attain a certain grade of metallic content to be fit for shipment."

---

[*] Published by permission of the Director of the U. S. Bureau of Mines.

[†] Algernon Del Mar, 'Differential Flotation of Lead and Zinc Sulphides', M. & S. P., Nov. 23, 1918.

On observing successful laboratory flotation machines of the mechanical-agitation type we find that when the pulp-density is 3:1, there is from 30 to 60 grammes of ore for every square inch of frothing surface. Let us see now if the test-tube, which was recommended a long while ago, has proportions that are consistent.

Take a test-tube of such a diameter that it gives a frothing area of 0.6 sq. in. The quantity of ore required is then, say, 30 grammes; and for a 3:1 pulp, 90 cc. of water must be added. But the ordinary test-tube of this diameter will hold only 85 cc. of water. It is eight inches long. We see that after making allowances for the volume of ore and air, the test-tube would have to be about a foot long. It is obvious that the adoption of these proportions in such a device would not be consistent. A loaded bubble that chanced to be at the bottom of the tube at the end of the agitation period would have to travel upward a distance of nearly 12 inches against a falling column of froth. Needless to say, it would be wrecked at the outset and buried beneath the column of ore.

Moreover, the test-tube has no facilities for discharging the froth.[†]

The device recommended here has been used at the North-West station of the U. S. Bureau of Mines at Seattle. It consists of two pyrex flasks, one of 250 cc. and the other of 500 cc. capacity. A rubber nipple is placed on the neck of the smaller one, so that when the flaring portion is ground off it will fit snugly into the larger, as shown in the photograph. To prepare a test, the smaller flask is filled with a mixture of ore and water of the desired consistence and emptied into the larger one, after which about three cubic centimetres of water is added. After the desired flotation reagents have been added, a stopper is placed in the flasks and we are ready to proceed with the test.

The procedure of testing is by means of hand agitation for, say, five minutes. The stopper is removed, the flasks are united, and, after a brief agitation, they are placed in the position as shown. The extra three cubic centimetres of water elevates the lower level of the froth so that it will overflow into a collecting-pan when the larger flask is removed. The agitation may be repeated as often as desired by adding a little extra water each time.

The efficiency, of course, is low as compared with the mechanical devices, but the relative floatability of minerals and the relative effects of flotation reagents may be determined quickly. There are two reasons why the efficiency is low: first, there is no opportunity for the froth to build up during the agitation period; second, a small quantity of gangue lodges on the bench formed by the union of the inner and outer tubes, and by joining the overflow reduces the grade of the concentrate.

The quantity of modifying reagents must be determined by calibrated devices; otherwise impressions may be misleading. This is demonstrated by the following example. When four drops of oil was added from a medicine-dropper the pyrite floated so freely that the results were adverse. The dropper was then calibrated, and it was found that four pounds of oil per ton of ore had been used. The test was then repeated with one drop of oil and the results were encouraging.

This device then has three points of advantage over the test-tube: It has convenient discharging facilities; it provides for desirable pulp-densities and a consistent area of frothing surface.

Quebec in 1918

Mineral production of Quebec during 1918, according to Theo. C. Denis, superintendent of mines, was valued at $18,572,595, an increase of 14.72%. There was increased activity in the extraction of the war minerals, and the gain in these over 1913, a pre-war year, was 13.25%. The principal substances were as under:

Product	Quantity	Value
Asbestos, tons	142,375	$9,019,899
Chromite, tons	35,749	770,955
Graphite, pounds	200,583	17,760
Magnesite, tons	28,564	1,016,764
Mica, pounds	882,121	201,055
Molybdenite, pounds	342,296	383,252
Pyrite (including copper ore), tons	125,446	1,319,690

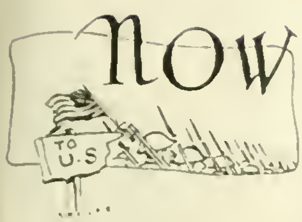
Chromite mining, it is feared, will decline considerably now that the urgency for it is past. An objection to the use of molybdenum is considered to be the irregular supply, but now that the industry is well established this should disappear. The graphite industry was unfortunate, and works were closed a great part of 1918. Good results are reported from flotation of this ore. There are 6125 men employed in the mining industry of Quebec.

TIN production of the Mount Bischoff company in Tasmania cost 7s.4d. ($1.76) per ton of ore mined during the last half of 1918. Mining is from open workings; the ore is carried by aerial trams and electric haulage; crushing is by stamps; concentration is by tables and jigs; and the black tin (oxide) is reduced to 99.87% metal in the company's own smelter. The output in the six months was 310,587 lb. Operations are highly profitable.

[†] The separatory funnel recommended by 'A Special Correspondent,' M. & S. P., July 24, 1915, and by O. C. Ralston and Glenn L. Allen, M. & S. P., Jan. 8, 1916, is faulty because the proportions are not good and the froth has to stand until the tailing is removed.

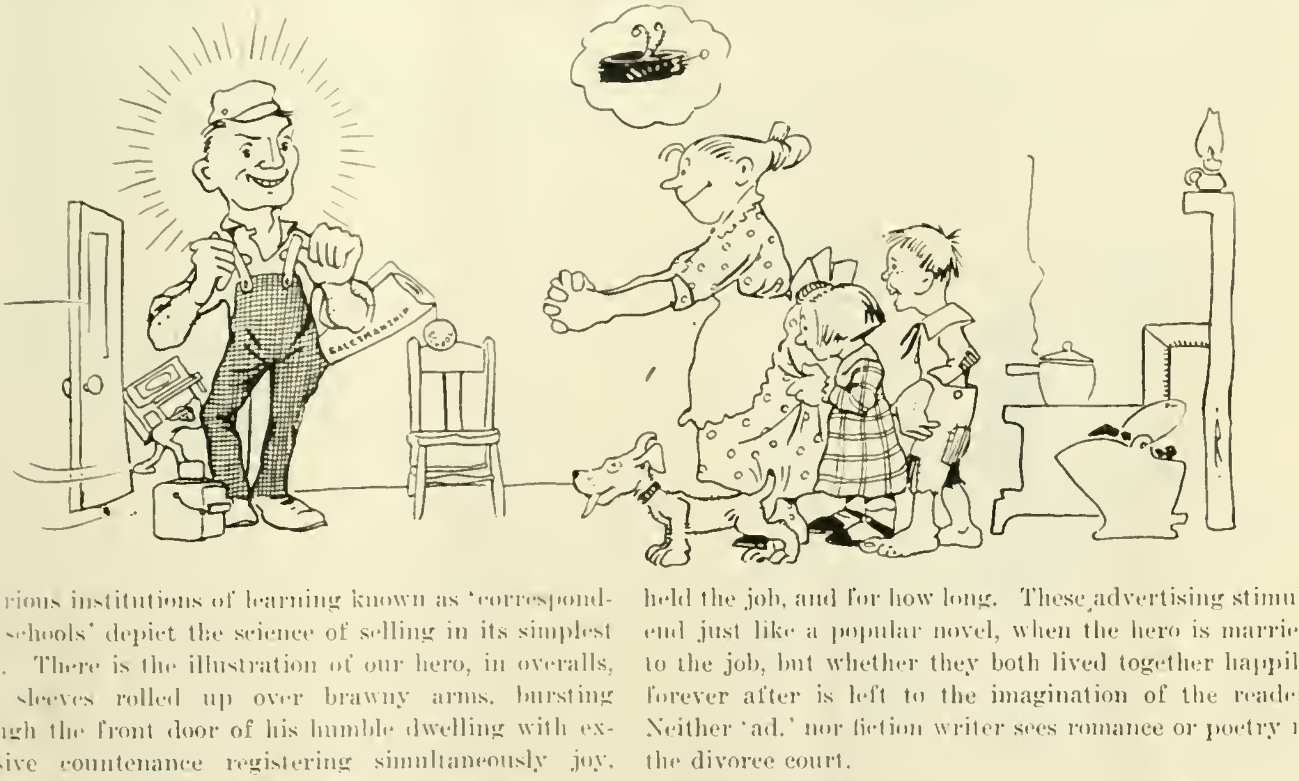
Selling: An Art

By CHARLES T. HUTCHINSON



Now that the War is over, all there is to do is to go out and sell everything we make. How simple it all sounds! What could be easier? Of course, it is generally deemed advisable to sell things at a price that will carry a profit to the seller, but even then, it is still simple. Just add whatever profit you would like to the cost, hire some salesmen, publish some catalogues, advertise, and, in the course of a short time, declare some dividends.

This is the idea that exists, in a more or less nebulous form, in the minds of a lot of people. The advertisements of various institutions of learning known as 'correspondence schools' depict the science of selling in its simplest form. There is the illustration of our hero, in overalls, with sleeves rolled up over brawny arms, bursting through the front door of his humble dwelling with expressive countenance registering simultaneously joy, pride, and exultation. He is greeted by friend wife with outstretched arms, her expression a reflex of the ditto joy, pride, and exultation. She is clad in apron and the customary other details. She has been preparing the 'pork and', against the homecoming of her liege lord. Two or more, as the case might be, of their offspring are clinging to their mother's apron, gazing with rapt visage upon their dad. It is easy to learn by the illustration that dad has done something big. Then comes the dialogue.



He. Oh, Abigail, what do you suppose has done gone and happened. The Boss called me into his office today, and said "Hector, my boy, entirely without your knowledge, I have had my eye on you these past forty years, and when I saw the lessons from the R. S. V. P. Correspondence Schools sticking out of your trousers pocket, I said to myself, 'Ecce homo', which means that from now on you are no longer a boiler-makers helper, but General Manager of Sales at a salary of umpty-steen bright golden ducats per annum."

She. Hector, my king, my prince! Now I can have a new hat that will make that odious Mrs. Smith green with envy!

Joy, wassail, finis!

Finis, that is where the trouble comes in. It is not disclosed, now that Hector has got the job, whether or not he held the job, and for how long. These advertising stimuli end just like a popular novel, when the hero is married to the job, but whether they both lived together happily forever after is left to the imagination of the reader. Neither 'ad.' nor fiction writer sees romance or poetry in the divorce court.

Without being unduly cynical, we prophesy trouble ahead for Hector, unless his training has been much more varied and comprehensive than that offered by any correspondence school, excellent as many of them undoubtedly are. A correspondence course in selling, or any other course of study through books, is as the ABC's to a Doctor's degree in literature.

Selling involves not merely a mastery of the science of organization, but a profound knowledge of the Book of Life itself, a knowledge that can only be acquired by omnivorous reading, acute observation, and an analytical mind, by which apparently insignificant facts and tendencies of the human race may be dissected, ticketed, labeled, and made to reveal the ideas, desires, and longings of that impossible creature known as the average man, or woman.

Take all of the gainful occupations, compile a mass of statistics out of which may be determined the average compensation per individual for each, and it will be found that the profession of selling—or business of selling, if you like—is the most highly paid of all. Thus is proved by the reductio ad dollar method that selling is the most difficult of them all.

It is not the purpose of this article to enter into a discussion of the minutiae of selling, the methods of organization, the canvassing of the field, the compilation of statistics, the preparation of an advertising campaign, the territorial maps, or the hiring and firing of salesmen. These things constitute the machinery, the plant equipment, the inanimate forces of selling. What are much more interesting are the more delicate shades and factors that influence and often control sales: these are about to be brought under the microscope, so that those who read will understand and sympathize with the problems of the salesman, the difficulty in his making good, and his large and toothsome pay-check if he does.

Jones, the star salesman for the Alpha Beta Manufacturing Company, has just returned from New York. His entry into the office takes upon itself the nature of a triumphal procession. Everybody grins, the proletariat in the outer office with envy, the Boss himself with congratulation tinged with relief. The strain has been a severe one, even those not in the confidence of the management knew that work in the shop was slack, and that a whole season's output hinged upon the success of Jones' mission, and, Jones landed the contract. Now he is home, the contract itself, all signed up by Presidents and Secretaries and things, together with what was most important, a nice fat check for the first payment, are about to be extracted from the well-worn leather brief-case and spread on the mahogany table before the admiring gaze of the Boss.

Let us sneak into the private office before the door is closed and listen to Jones as he reports the intimate details of just how it all happened.

"Now Jonesy, old boy, have a cigar, and sit down and rest yourself for a while," said the Boss with a happy smile. The cigar was produced, from a special box covered with revenue stamps. That was some eigar. "Have a light, Jones. You will find that other chair more comfortable." Jones puffs away for a minute. It is his minute, and he is enjoying it hugely.

"Well, sir," replies our hero, after gazing ruminatively at the accumulating ash, "the real history of that interesting typed document which you see before you dates back a good long while. You remember the old yarn about the pig that started the war, and the cow that kicked over the lamp that set fire to Chicago? This particular job is very much the same sort of thing.

"When that Scotchman came in with the design for the particular piece of apparatus which is now the backbone of the business, you may remember that the office-boy, like most office-boys, happened to have a grouch, and was just going to tell him that you were not in, or something, when you came out of the office-door and stopped long enough to look at what the Scotchman had, became interested, and the result was that he was given a job in the shop and is now our general superintendent. That little appliance was so good that it is now our best feature. So, you see, that is where this particular contract really started. In other words, if our stuff wasn't right, all the salesmen in the world wouldn't have done one bit of good in this case, or any other.

"Then another thing. You remember that habit of yours, pinning the envelopes on letters after they are opened instead of chucking them in the basket? That is another factor in getting this job. You will see why as the story unfolds.

"A third factor is a bit of elementary psychology, based upon the tendency of the human mind to want something immediately if told that it can't have it.

"The fourth factor is the efficiency of the modern telephone; the fifth lies in the fact that you made me fighting mad with those confounded telegrams of yours; and the sixth, and perhaps the most important one of all, lies in the element of luck, without which we might have been thoroughly licked in spite of ourselves.

"I landed in the big city on time, for a wonder, and, as soon as I had been wafted to my hall-bedroom at the Splitmore, after running the gauntlet of piratical taxi-drivers, door-men in general's uniforms, bell-hops, and other automatic coin-collectors, I sat me down to the writing-desk and wrote a line to the president of the company with whom we had been corresponding to let him know that I was in town and wanted to see him."

"Why didn't you go to see him, or call him on the phone?" asked the Boss.

"Because the only address I had was a post-office box number," replied Jones. "You remember that the property where the stuff is to be used is in Montana, and I hoped that they would have a regular office in the city. A diligent search through the telephone books, and also some sixteen directories didn't help me a bit, so there was only one thing to do, and that was to drop him a line: so I did.

"The next two days slipped by like nothing. I tried to round up some other prospects, but there was nothing doing. The weather was infernally hot, so all the natives who had the price were at the seashore, and those who hadn't didn't interest me at all.

"Then you started those confounded telegrams. How would you like to be sweltering away in a big city, thousands of miles away from home, and doing your darnedest, and then get something like this. 'If you don't land that job, this place will be shut down when you come back', or 'Make a noise like an order or stay in the East permanently'? Maybe you think I wasn't mad. I was determined to land that job or bust, and then wire you to go chase yourself forever, as far as I was concerned. I suppose all you really wanted was to arouse the fighting spirit; anyway, you certainly did."

"You will have to forgive me for the rough stuff, Jones," grinned the Boss. "Anyway, it was good medicine. It worked."

"All right," laughed Jones. "I am so darned good-natured now, that I don't care. But to resume. Two days, three days, and then four days passed, and I didn't hear a single word from him. I kept getting more and more nervous, until finally, one evening I was sitting in my room scratching my head in a vain effort to start an idea of some kind, when I went to my grip and absent-mindedly took out all the correspondence dealing with the case. Turning it over, I noticed a letter with an envelope pinned on. By Jingo: what do you think? The postmark was New Brunswick, New Jersey. That fellow must have been in New Jersey, in fact, must be staying there, perhaps with relatives.

"I grabbed the telephone, and soon was communing with the operator in my most honeyed tones, somewhat in this strain. 'Please, oh please, call New Brunswick, New Jersey. Then, ask the telephone operator if, by any happy chance she knows of a Montana mining man, who has planted his whereabouts in that beautiful suburb, and further, if said mining man perhaps is so situated as to be accessible to the telephone.' Then followed many objurgations as to the great and vital importance of this matter. After that down I sat, to possess my soul in patience, and wait, and fume.

"Half an hour passed to the great beyond. Then another half-hour. Then tinkle-tinkle went the bell. I jumped for the phone. Here is the way I got it.

"TH' PARTY YOU WANT IS ATTA FARM 'BOUT FI' MILES OUT D'YOUWANTUM ?"

" 'Th' party you want is atta farm 'bout fi' miles out. D' you wantum?"

"Did I want him? I wonder. By the great horn spoon, he was on the wire in less than five minutes—so fast that, at first, I was almost tongue-tied. However, I soon got going, and told him what I wanted in good vigorous English too. He was most indifferent, in fact, he practically said he didn't care a hang whether he saw me or not, and wasn't ready to talk business anyway. Then he hung up the phone.

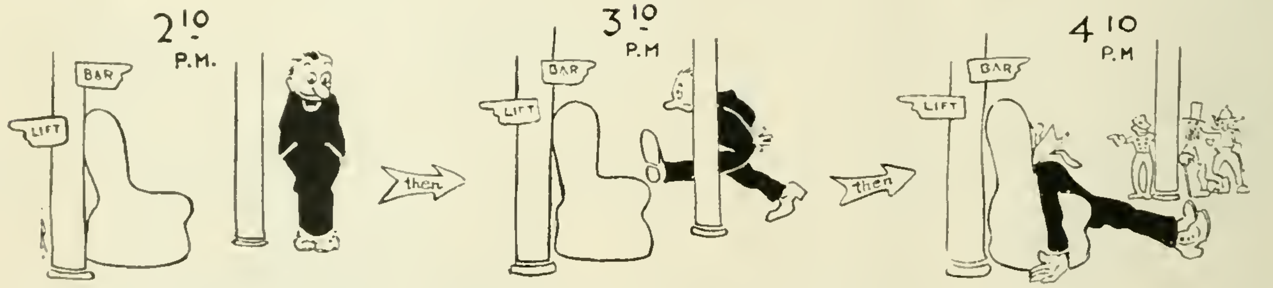
"I was sick, just sick over it. And the worst part of it was, that there didn't seem to be anything to do about it. Anyway, I turned in, and tried to get some sleep in the hope that some new hunch would appear in the morning.

"That was tough," remarked the Boss.

"You know it," returned Jones, with emphasis. "Well, next morning about seven, while I was dressing, my 'phone rang, and there he was again. To my surprise, and delight, he said that he didn't just get who I was over the 'phone the night before, and he had just received my note, and would try to get into town before I left. He explained further that his partner was in England trying to float bonds to raise the money needed, and that, until he came home, there would be nothing doing. We chatted pleasantly enough, and I hung up the 'phone with a heavy heart, and prepared to start for home in two days.

"I cleaned up the few odds and ends remaining, and, on the morning of the day I was to leave, I called him again, just for a spec. By jingo! he had received a wireless from his partner that day. The money was raised and the ship his partner was on would dock that day at noon. Well, you know about the drowning man and the straw. I stood up on my hind legs, and simply burned up that telephone wire. Told him that he must, MUST, MUST, meet me that afternoon, and finally I simply talked him into consenting. He was to show up at two o'clock, and bring his partner.

"At two, I was pacing the lobby. At three I was running around the lobby. At four, I was gasping for breath, my glazed eyes indicating that all was lost. At four fifteen, in they came. Do you know, I bet they don't know yet what happened to them. I had a head of steam on way above the safety mark, and, as soon as they got into my room I went after them. You see, I had to get this job signed up before they had a chance to see any of the other fellows, and I didn't let any grass grow under my feet.



"They bucked, and bucked. The book of a thousand excuses was completely used up, and the final clincher, was simply this: that the prices I had quoted were based upon that bargain-sale lot of brass you picked up, and if they didn't take advantage of the offer within an hour, all prices would be immediately withdrawn, and they would lose thousands of dollars by their procrastination.

"That was a clincher. Finally, he turned to his partner and said: 'Waal, Jimmy, what do you say? Shall we buy?' 'Might as well, Hank,' drawled the partner; and buy they did. The fountain pen was produced, everything was signed, sealed, and delivered, check and all; and, to cap the climax, when I suggested that it had been dry work for all of us, the partner looked at me sadly, and said: 'Me and Hank don't never touch a drop, and, young man, you would be a sight better off if you didn't nuther.' They blew, and I collapsed in a chair."

Large organizations, international in their scope, go to great lengths in the compilation of individual statistical data on prospective buyers. Such matter is prepared carefully and painstakingly from a great many sources of information, and is elaborately card-indexed for ready reference in case of emergency. The methods are, in some cases, strikingly similar to those observed by criminal identification bureaus. Everything about the man, save his thumb-prints, photograph, and Bertillion measurements are available.

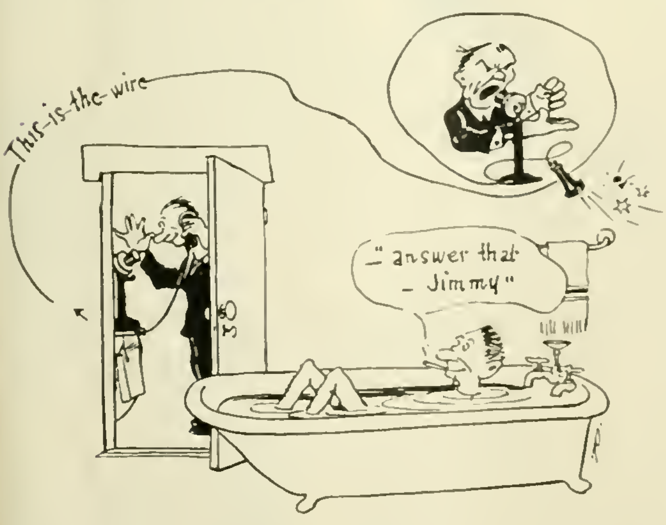
Here is the way it operates. Suppose the word is passed along that one Snodgrass, chief engineer for a great corporation, is about to collect data dealing with the proposed installation of a great plant-addition involving the purchase of vast quantities of apparatus and supplies. The scouts for the supply-houses and manufacturers know this long before any inkling appears in the daily press. Instantly the great general staff of the manufacturer clears decks for action. Interest centres on Snodgrass as the man who will in all probability be a big factor, if not perhaps the final factor, who will say yes or no as to who shall get the business.

Resort is first had to his dossier. There are disclosed all sorts of interesting facts. He is dissected, analyzed, and laid on the table under the microscope of the general staff, which is about to plan the campaign that will ultimately result in victory for their forces. Let us look over their shoulders and learn a thing or two about Snodgrass.

We find that Snodgrass is 49 years old, where he was born, full particulars as to his scholastic training, the name of his alma mater, the courses he took, and whether he went in for athletics or other forms of activity engaged in by the student body, whether he was a 'barb', or perhaps a member of the exclusive Alfalfa Delts, Eta Bita Pi's, or Moo Moo Cows. Then comes his professional record, the names of his former employers in chronological order, his engineering society affiliations, and his clubs. His professional fads are disclosed by his contributions to the engineering society proceedings or the technical journals, his social affiliations by his clubs. Then comes data as to his family, and hardly less important, the social activities, fads, and fancies of his wife. Under the heading of remarks, we learn that Snodgrass has a marked aversion to salesmen, likes to drive a high-powered car, suffers from indigestion, is a teetotaler, quick-tempered, plays golf for exercise, and hates like thunder to lose, is amenable to flattery if tactfully applied, in short is what is known in selling parlance as an all around hard case, but, to use another salesman's axiom, the higher they are, the harder they fall.

Pursuing the work of the general staff a little farther, Snodgrass' assistants are also smoked out with the same infinite care. Their influence and power of suggestion are not overlooked. Then various dignitaries are set to work on the job, each with a definite assignment, and the entire strength of the business Wilhelmstrasse is turned loose on the most interesting big-game hunt known to the commercial world. Of course, there are many of such campaigns under way continuously, but this, in brief, is the modus operandi. From the time of its inception to its consummation, one way or the other, the iron is kept hot at all times. Frequently the period of negotiation may represent years. Sometimes, there will be several flare-ups and die-downs before the deal is consummated, but it is a case of eternal vigilance, and Heaven help the salesman who is caught napping. His reputation and his job hang in the balance.

Competition is keen, and rivalries are intense. Out of it come many amusing contretemps, of which the following is an example: A salesman, who had been following up a prospect on a big contract for some time, succeeded in establishing himself on such a firm personal footing with the buyer, that, when the buyer went to New York, the salesman met him at the station by prearranged plan, and accompanied him to his hotel. The buyer adjourned to the bath-room to remove the stains of travel, leaving the salesman to amuse himself in the bedroom meanwhile. The buyer safely in the tub, the telephone rang. "Answer that, Jimmy," came the orders from the tub. Jimmy did. It was the chief salesman of Jimmy's bitterest rival, and, then and there, over the phone that salesman, thinking that he was addressing the buyer, proceeded to rip Jimmy up the back, his concern up the back, and his goods up the same place. Then forthwith, when the salesman paused for breath, Jimmy took a hand, and, impersonating the buyer, proceeded to read the salesman a lecture on the fallacy of knocking one's competitor, decency in sales tactics, and other things in such plain, vigorous United States, that said salesman disappeared from human ken when the story got out, as such stories always do, and Jimmy got the job hands-down.



In the use to which such personal data on individuals is put, is involved the necessity of consummate skill and an infinite amount of tact. Many a good sale is lost, and a permanent prejudice established through a lack of appreciation of these facts. The amour propre of the buyer must be carefully observed, that it be not bruised or ruffled by overzealousness.

A buyer, who had the placing of a large amount of business every year, had occasion to go East at one time, and, of course, the scouts of a certain business concern duly apprised their principals of the fact, together with the usual data as to the time of his arrival in the big city, his favorite hotel, and the kind of hospitality which, they thought, would appeal to him. As this particular concern had fared rather ill at the hands of this buyer, they thought to grab this golden opportunity with both hands, and unfortunately overdid it badly.

When the buyer arrived, he was met by the genial type of spellbinder, who, willy-nilly whisked the buyer and his grips into a limousine de luxe and shunted him into his hotel, had a whole procession of bell-hops and things rush out to meet him and conduct him into a Louis Kansas suite which looked like $50 per day, filled his key-box with cards to clubs, kept the telephone tinkling constantly with theatre invitations while the poor buyer was trying to take a bath, and generally made an infernal nuisance of himself. As a result, the buyer, as soon as his entertainer vouchsafed to leave him for a minute, quietly sneaked out of the hotel and went to a friends' home and took with him a contempt and disgust for that particular concern which has lasted to this day.

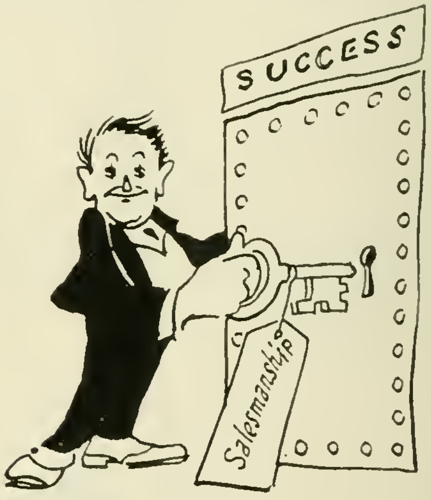
Contrast this with the adventure of a certain well-know master salesman for a steel manufacturer. There was a big deal on for certain steel products with a foreign country. Millions were involved. After much scurrying around, the master salesman met the visiting foreign delegation at Sandy Hook, with the assistance of a sea-going tug, and, before the vessel docked, he was in possession of the whole circus. He had spent much time studying up the characteristics of the people with whom he was to deal, and, in consequence, his conduct to them was a model of suavity, diplomacy, and finesse. The visitors were charmed to find, in one supposed to belong to an uncouth race, the model of a gentleman of their own standards.

That night, the inevitable dinner was arranged in a private dining-room of a great hotel. The hostelry, given carte blanche in every particular, outdid itself. Rare exotics adorned the festal board. The silver and table appointments would have graced the table of the Czar himself, while spotless napery added the final touch to what was to be a gastronomic masterpiece.

Enter the visiting foreign delegation, resplendent in uniforms such as were only possible in the old world under the ancient regime. Gold lace, orders, decorations, medals, and monocles; fiercely waxed upturned mustaches and clanking sabres, there was the very breath of romance, the real Prisoner of Zenda atmosphere. Of course, there were toasts, drunk in hollow-stemmed glasses filled with rare vintages. The senior officer among those present proposed "His Imperial Majesty, the Czar." In a flash, all were on their feet. Heels clicked, sabres flashed aloft. "The Czar." Crash! Every glass went smash against the wall.

Then comes the master salesman. "Gentlemen," he said, "I long have admired the delightful custom of your country, that prevents the profanation of any glass after dedicating it to the sacred health of his Imperial Majesty. Now, I will show you how it is done in these United States. Gentlemen, his Excellency the President of the United States." All rose. Again the click of heels, the flash of sabres, and glasses aloft. No sooner drunk, than the master salesman seized the table-cloth, and with one sweep of his arm, one mighty crash, threw everything on the table to the floor.

Then pandemonium broke loose. Floor clerks, house detectives, bell-hops, and sundry other fauna that infest the halls and corridors of great hostelries, galvanized into action, rushed frantically about. Cheer upon cheer rose through the smoke-laden air and impinged upon the ceiling, searing the life out of the old ladies on the next floor. Such magnificence, such lofty contempt for expense! Thousands of dollars worth of gorgeous cut-glass smashed to bits in honor of the President of the United States! This great man, this superb American, with his dramatic appeal to the imagination of the most temperamental people in the world, held the situation in the hollow of his hand. What chance did the poor plodder, the spectacled master of blueprints, specifications, and tests stand? Where, oh where, were the efficiency engineer, the advertising manager, and the correspondence school-graduates? Who got the order? How can you ask?



Mineral Production of Canada in 1918

Preliminary figures for the past year, prepared by John McLeish, have just been published. The total value of all products was $210,204,970, an increase of 10.8% when compared with 1917, and 44.3% with 1913.

Metallic—	Quantity	Value
Cobalt metal and oxide at $2.50, pounds	1,347,544	$3,368,860
Copper at 24.628c., pounds	118,415,829	29,163,450
Gold, ounces	710,526	14,687,875
Iron pig from Canadian ore, tons	47,444	1,204,703
Iron ore sold for export, tons	112,886	469,352
Lead, at 9.25c., pounds	43,846,260	4,055,779
Molybdenite (MoS$_2$ content at $1.15), pounds	377,850	434,528
Nickel at 40c., pounds	92,076,034	36,830,414
Platinum, ounces	39	2,560
Silver at 96.772c., ounces	21,284,607	20,597,540
Zinc at 8.159c., pounds	33,663,690	2,746,620
Total metallics		113,563,111
Non-metallic—	Tons	
Asbestos	141,462	$8,930,805
Chromite	21,904	807,122
Coal	14,979,213	55,752,671
Feldspar	20,232	117,379
Fluorspar	7,362	135,712
Graphite	3,051	270,054
Gypsum	152,287	823,006
Magnesite	39,365	1,016,765
Mica	... ...	268,375
Pyrite	413,698	1,688,991
Talc	18,190	112,727
Total non-metallics		78,230,195
Structural materials and clay products		18,411,064

Increases in quantities were: cobalt, 24.8%; copper, 8.4%; lead, 34.6%; molybdenite, 31.6%; nickel, 11.8%; zinc, 13.8%; and asbestos, 2.9%. Gold decreased 3.8%, and silver 4.2%.

Production of all minerals by Provinces was:

	1917	1918	Increase or decrease, %	
Nova Scotia	$21,104,542	$22,754,780	+$1,650,238	7.82
New Brunswick	1,435,024	2,111,816	+ 676,792	47.16
Quebec	17,400,077	19,534,409	+ 2,134,332	12.26
Ontario	89,066,600	94,084,420	+ 5,017,820	5.63
Manitoba	2,628,264	3,197,697	+ 560,433	21.67
Saskatchewan	860,561	894,501	+ 33,940	3.94
Alberta	16,527,535	23,298,118	+ 6,770,583	40.97
British Columbia	36,141,926	42,080,741	+ 5,938,815	16.43
Yukon	4,482,202	2,248,398	— 2,233,804	49.83
Dominion	$189,646,821	$210,204,970	+$20,558,149	10.80

Ball-Mill Operation

By E. W. DAVIS

*From an elaborate series of tests, the following conclusions were deduced:

In the discussion, only the force of gravity and centrifugal force have been considered. In a mill containing water and ore, as well as balls, the force of adhesion ought to be considered. This force not only tends to hold the balls and ore together, but also tends to hold them against the lining of the mill. Just how important this force may be under ordinary operating conditions is difficult to say. It was shown, however, in a model mill, that adhesion tended to hold the particles together in their parabolic paths, and almost entirely eliminated the accidental particles that fall near the centre of the mass. It is impossible to apply the results secured in a small mill to a large mill in this respect, however, as adhesion varies inversely with the size of the particles considered. Adhesion also varies with the moisture, so the mill operator has a convenient means of controlling this force so as to produce the best results.

It is important to prevent slipping between the charge and the lining of the mill; the tendency to slip is much smaller with large charges than with small ones. If the friction between the charge and the lining of the mill is not great enough to carry the particles up high enough, the efficiency of the mill will be greatly reduced and the lining of the mill will be worn away rapidly. Flat sides will also appear on the balls, and the cycle of the charge will be slow and irregular. In an open trunnion-discharge mill, the pulp will not flow from the mill regularly, but will come in pulsations. Lifters or roughened liners are therefore desirable, as they ensure a greater coefficient of friction.

The following conclusions may be stated:

1. By use of formulas

$$K = -0.024 + 0.39\sqrt{7 - 10P} \text{ and}$$

$$N = \frac{48.948}{\sqrt{D}\sqrt[4]{1 + K^2}} \text{ in rev. per min.}$$

proper theoretical speed for operation may be computed.

2. This speed is correct only when there is no slipping between the charge and the lining of the mill, and when the pulp is not so thick as to produce strong adhesion between the particles.

3. In actual practice it may be found that more effective crushing can be done at some other speed, but it would appear that the variations above or below this theoretical speed should be small.

4. When operating at the speed shown by the second formula the crushing is done largely by impact.

5. At speeds lower than N (second equation) the proportion of the crushing done by attrition is increased.

6. At speeds higher than N (second equation) the proportion of the crushing done by impact is increased.

7. The amount of crushing done depends upon the number of blows struck and the work done at each blow.

8. The number of blows can be increased by adding to the number and decreasing the size of the balls.

9. The work done at each blow can be increased by adding to the weight of the ball and by increasing the diameter of the mill.

10. From this it follows that mills of larger diameter should be charged with smaller balls and mills of smaller diameter with larger balls, when working on the same feed.

11. The proper operating speed of a ball mill varies inversely as the square root of the diameter.

12. The proper operating speed of a ball mill increases as the size of the ball load increases.

13. Due to interference between the balls, the volume of the charge should not be over 60% of the volume of the mill.

14. Unless great care is exercised to prevent slippage, the volume of the ball charge should not be less than 20% of the volume of the mill.

15. It would then seem that a ball charge that occupies between 25 and 50% of the volume of the mill will give most satisfactory results.

16. In an 8-ft. mill, running at 22 r.p.m., with a 28,000-lb. charge of 2-in. balls, there will be an average of about 1,000,000 blows per minute; each of these blows will be equivalent to dropping a 2-in. ball 5 feet.

Conclusions as to ball wear were as follows:

1. In any mill, the rate at which the weight of any ball decreases is directly proportional to its weight.

2. In any mill, the rate at which the diameter of a ball decreases is directly proportional to its diameter.

3. In any mill, the rate at which the surface of any ball decreases is proportional to its surface.

4. Since the rate at which a ball loses weight varies as the work done upon it in the mill, it follows that the work done in wearing (or crushing) the ball, varies as the weight of the ball. This is seen to be Kick's law.

5. It then appears that Kick's law holds true for the ball wear in a rotating mill.

6. The natural tendency is for the small balls to accumulate in the mill charge.

7. Since these small balls do very little crushing, and exclude ore and larger balls from the mill, if allowed to accumulate too long, a marked decrease in crushing efficiency will result.

8. Since the large ball is just as likely to strike the small pieces of ore and the small ball is just as likely to strike the large pieces of ore as the reverse, it would seem that all the balls should be of a size to crush any of the particles of ore.

9. This means that the balls should be as nearly as possible of a uniform size.

10. Since spheres of uniform size provide the greatest amount of interstitial space, a mill charge composed of balls of uniform size will allow freer migration of the ore particles than a charge containing balls of different sizes.

*Abstract from Bull. 140, A. I. M. E., February 1919.

The Fourth Dimension

By JOHN ROGER

This is a fertile source of discussion among those interested in puzzles. No one has ever seen the fourth dimension or can tell us just what it is, but it is said that it must exist because we can write an equation for it.

The first question to consider in this connection is what is meant by dimensions; assuming these to be in an elementary way linear, superficial, and volumetric, that is, first, second, and third dimensions. Length, breadth, and thickness are not three dimensions, but are three measures of the first or linear dimension.

It seems to be customary to assume that the square of 12 inches (linear) is a square foot and that the cube of 12 inches (linear) is a cubic foot. It would be hard to conceive of any proposition more nonsensical than this. The definition of a line is something which has neither breadth nor thickness but only length. Length without breadth or thickness does not exist, except in theory, as it occupies no space. It, therefore, follows that it can make no difference how many times the length is squared or cubed, it can represent neither surface nor volume. Length without breadth or thickness materially is nothing, therefore the square of 12 linear inches is 144 linear inches and the cube of 12 linear inches is 1728 linear inches; it represents neither surface nor volume. The four 12-inch lines enclosing a square foot are no part of the enclosed area.

The same holds good as between superficial and volumetric dimensions. A surface without thickness represents no matter or displacement and does not represent quantity unless the third dimension is given, and these dimensions are not measurable one by the other. The square of 12 superficial inches is 144 superficial inches and the cube of 12 cubic inches is 1728 cubic inches. But to say that the cube of 12 linear inches is 1728 cubic inches is nonsense, as a linear inch has no volume and the cube of nothing is nothing. When we say 12 inches cube, it is only a simplified way of saying the cube of 12 cubic inches.

It must, therefore, be evident that there is only one measure of space and that is volumetric. Measures of length and surface are measures in space and not of space. No amount of surface can make a cubic inch and no amount of length can make a square inch. Volumes are, therefore, measured by units of volume, we may make the unit what we please and the multiples of it may be given as fourth, fifth, or sixth powers of any stated number of units, and these are measurable by such volumetric units—not by any linear measure. When we measure a rectangle 2 inches by 3 inches by 6 inches, we unconsciously assume through usage that 2 cubic inches by 3 cubic inches by 6 cubic inches equals 36 cubic inches. Three linear inches plus 3 linear inches plus 6 linear inches is necessarily 12 linear inches. In other words, we must determine beforehand whether we are calculating in the first, second, or third dimension; and in dealing with space there is only one dimension, namely, the third or volumetric. With lines we enclose surfaces and with surfaces we enclose volumes, but neither the lines nor the surfaces are any part of the volume. The so-called fourth dimension is, therefore, simply a multiple of the selected unit of volume and has no mathematical significance.

The Sweeney Mill at Kellogg, Idaho

By R. S. HANDY

*This plant was turned over to the Bunker Hill & Sullivan company by the Federal Mining & Smelting Co. on July 9, 1918. The work of sampling and estimating the contents of the tailing dump was started immediately, and 1000 tons of the material placed in the mill-bins for a working-test, in order to determine the possibilities of profitable treatment.

The fine jigs, which had been handling material below three millimetre in size, were taken out of the main building. Their feed was sent to two 20-mesh trommels. The oversize from these passed to the coarse jigs. The undersize was spouted to the old slime-house, where it was classified and treated on tables and vanners.

The 1000-ton test indicated that treatment of the tailing was commercially practicable, so the plant was remodeled for convenient handling of the tailing as well as ore from lessees' operations in the old Last Chance mine workings. The changes consisted in the installation of 11 Wilfley tables on the floor that used to contain the fine jigs; a drag under the 3-mm. trommels to carry the undersize to the 20-mesh trommels; Calumet classifiers to classify the undersize of the 20-mesh trommels for table-feed; and a flotation plant on the west side of the coarse-jig floor. The flotation plant consists of three Bunker Hill and two Callow cells, it takes its feed from a 30 by 8-ft. Dorr thickener, which is on the ground west of the mill. The feed to the Dorr thickener is the overflow of the Calumet classifiers. Some of the rolls and the methods of feeding them have been somewhat changed. The coarse jigs, elevators, and Huntington mills were not materially altered.

The remodeled mill dresses 400 tons of tailing from the old dump in 16 hours, or it can concentrate 200 tons of lessees' ore in the same period. The old dump-tailing assays 1¾% lead. While operating on this tailing two valuable products are made. First, a middling that is taken off the jigs and tables assaying 10% lead, 4 oz. silver, and more than 20% excess of iron over silica, for which reason it is especially desired by the smelter for fluxing. The second product is the flotation concentrate, which assays 25% lead and 18 oz. of silver per ton.

A great deal of trouble has been faced in getting railroad transportation of the dump-tailing and lessees' ore to the mill, but the plant itself is working satisfactorily. Flotation, as was expected, presents a difficulty, on account of the high content of flocculent oxidized matter in the feed, and will require further study.

The Use and Abuse of Crucibles

By A. C. BOWLES

A few days ago, a local foundryman called me up and complained, in language more forceful than elegant, that the last batch of crucibles he had received 'was rotten' and that they fell to pieces before he was able to get even one heat out of them. He asked indignantly what we were going to do about it. Of course, I told him that I was sorry he had trouble and that we would make good any crucibles proved defective, but that I would like to see the crucibles to determine, if possible, the cause of their failure. To make a long story short, he had attempted to dry them in the moist atmosphere of the core-oven, with the inevitable result that they had scalped upon coming into contact with the fire.

Crucibles respond so readily to proper treatment, that it is worth while emphasizing again the few points that have to be observed if the maximum of service is to be obtained from graphite pots. There is nothing new about the right procedure. Most crucible users have known it, but probably on account of the stress of business during the past few years, have neglected to make use of their knowledge.

The manufacturer is not infallible and occasionally a bad batch of pots slips through, but the complete system under which he works, and the long years of practice in repeating the same operation, reduce the chances of mistakes on the part of the factory to the minimum. It is safe to say that 90% of the failures of crucibles are traceable directly to poor treatment on the part of the user.

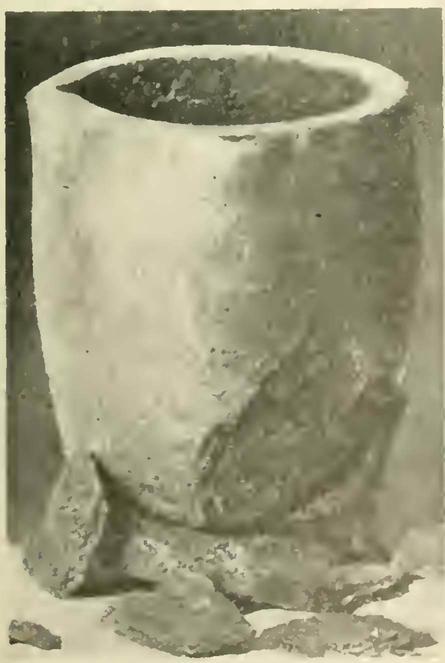
The principal cause of the failure of crucibles is the lack of proper annealing. When the crucible comes from the kiln it contains but ½% of combined moisture and in this condition it is impossible to scalp it. However, during transportation from manufacturer to user, it, like salt, absorbs moisture from the atmosphere, and once absorbed a temperature of not less than 250° F. is required to dispel this moisture.

Most crucible troubles occur in small shops. The large consumers have found it well worth while to equip their plants with drying-ovens especially to dry and anneal their crucibles before they are put into the furnaces. Whether annealing in a special oven or on top of the crucible furnace, there are four points that must be observed.

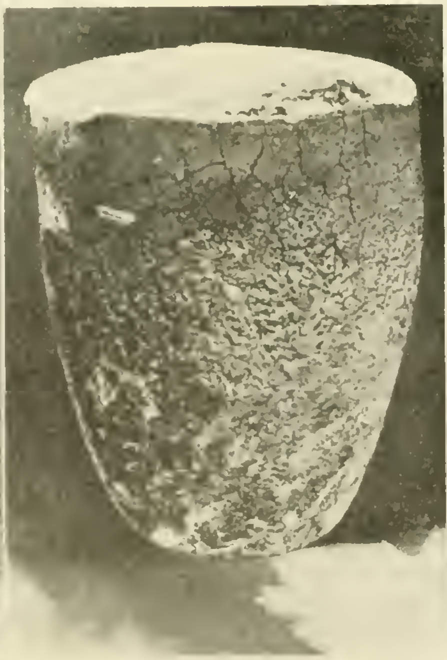
1. The temperature must go above 250° F.
2. This temperature should be reached gradually.
3. This temperature must be held a sufficient time to allow the moisture to thoroughly disappear.
4. The crucible must go into the fire with a temperature above 250° F.

It is a mistake to think that after the first three rules have been followed, the crucible has had its annealing and is impervious to moisture, for, if allowed to cool below 250° F. it will again take up moisture just as readily as the first time.

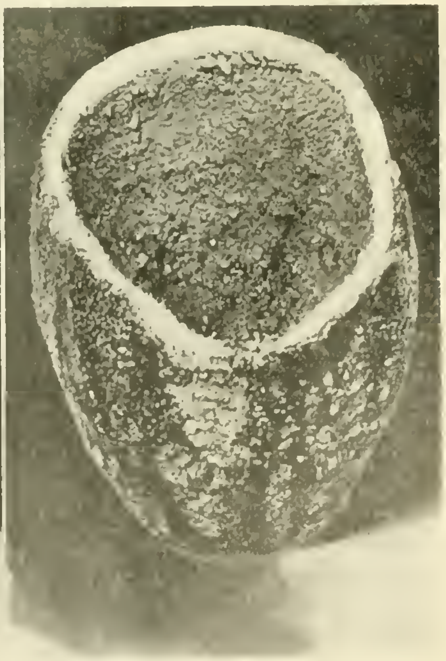
Another enemy of the crucible is mis-shapen tongs. When the crucible is hot, it is in a somewhat plastic condition and is easily squeezed out of shape or ruptured. The best tongs are the basket variety which grab the crucible both below and above the bilge and hold it firmly without squeezing. It has been found good practice to have an iron crucible cast, over which the tongs can be straightened and shaped at frequent intervals. This method is not only much quicker and simpler, but gives



CRUCIBLE BURST IN FIRE ON ACCOUNT OF MOISTURE



RESULT OF ALLOWING FLAME FROM OIL-BLAST TO TOUCH CRUCIBLE



CRUCIBLE SQUEEZED AND RUPTURED BY BADLY-SHAPED TONGS a better result than sending to a blacksmith. Some shops find it advisable to have tongs of two sizes: one for the new crucible and one for the old pot, which is considerably smaller.

In using an oil-furnace, the flames should never be allowed to play directly on the crucible, as scoring will follow, and the crucible will soon wear through on that side. In addition, one side will heat faster than the other, which is also bad practice. Oil-furnaces giving a rotary flame, seem to be the most satisfactory and to give the most even heat on all sides of the crucible.

The use of wet coke is also bad practice because steam comes in contact with the crucible and forms checks known as alligator-cracks. These will likewise form when a crucible is exposed to the moist gases on top of the furnace, while it is being annealed. Therefore care should be taken when annealing a crucible on top of the furnace, to see that it is kept away from direct contact with the flame.

The activities of the furnace-tender with his iron poker often shorten the life of the crucible. Many shops make a practice of keeping account of the number of melts each tender gets from a crucible so that the careless tender can be checked, and the average number of heats increased.

The number of heats obtainable from a crucible depends largely on the metal to be melted, and on the temperature required for the melt. A crucible that will last only three or four heats with nickel will last 25 heats with copper, or 40 or more with composition metal. If a flux is used, it lowers the life of the crucible by attacking the clay that holds the graphite together.

In general poor results are caused to a large extent by poor treatment. More attention to the details of storing and annealing the pots and to their treatment while in the furnace will pay large dividends in the increased service obtained.

Filter Litigation in Australia

In the Supreme Court of Western Australia on December 23, Justice Burnside delivered his reserved judgment in the action brought by the Moore Filter Co. of Portland, Maine, against the Great Boulder Proprietary Gold Mines, Ltd., for alleged infringement of patent.

The hearing was started on September 2, and lasted for several weeks. Plaintiff alleged a breach by defendant of certain letters patent assigned to it by George Moore, the original grantee, in 1907, for an invention for improvements in filter processes for the extraction of gold from unleachable slimes, dated August 21, 1903. Plaintiff claimed an account of profits derived by the defendant from its alleged breach, or, at its discretion, an inquiry as to damages arising from the use of the processes between 1907 and the date of the issue of the writ. Defendant denied infringement of the patent, which it claimed did not possess the number of necessary elements of validity. It alleged that the patent was the amalgamation of four inventions patented in the United States. Plaintiff, it further contended, had brought the action without having complied with the provisions of part 8 of the Companies Act, 1893.

In the course of judgment, the delivery of which occupied an hour and a half, the Judge traced the history of the extraction of gold from slime, and exhaustively reviewed the various phases of the patent in question, touching upon the objections raised by the defense under the Companies Act. He held that while plaintiff had not complied with the provisions of the Act, its non-compliance, though rendering it liable to penalties, did not preclude it from bringing an action. Dealing with plaintiff's claims in the patent, he said that he found them far from clear and precise, but it was impossible to say that they were so bad as to leave a doubt in the mind of the worker skilled in the art of gold extraction as to the invention, which the patentee claimed as his monopoly. The question of novelty raised by the defense was determined by ascertaining whether the combinations claimed were novel for the most part. They were, in fact, novel. All the elements of which they were composed were old, but nobody had previously brought them together in the exact manner of the patentee. It was the novelty of the combination that made the claim. As to the issue whether the combination was useful, he had come to the conclusion that at the date of the grant the plaintiff had not invented what he now said he had. There were difficulties to be overcome that the plaintiff could not foresee, against which he had made no provision. Some of the combinations claimed might work, but all, the Judge was satisfied, would not. As to the element of invention, the evidence went to show that the problem still remained, though further improvements might have followed and that the ordinary worker skilled in the art, who was called in to operate the machine, with nothing more than the Western Australian patent and specifications, would not, without much experiment, arrive at a successful result. It was contended that the patent was a pioneer and a master patent. The patent was for the principle. In his view the claims disclosed no principle such as was or might be the subject matter of the patent. There was nothing to indicate the claim to the principle. The patent was for a mechanical combination, and it was not alleged that this had been infringed. In his opinion, the patent was not valued, and judgment should be entered for the defendant, with costs.

The Great Boulder mine has yielded $55,680,000 from 3,425,000 tons, and paid $26,250,000 in dividends.

[The filter apparatus used by the Great Boulder company at Kalgoorlie is known as the Ridgway. It consists of a 'basket' of leaves that are suspended at the end of an arm, which first lowers it into the slime-tank for formation of cakes, then lowers it into another tank for washing, finally raising the basket over a mixer for discharge. The machine is ingenious, simple, works rapidly, and gives good extraction at low cost.—EDITOR.]

*Abstract from Monthly Journal of Chamber of Mines of Western Australia, Dec. 1918.

Mr. Bayliss on Mining Conditions

Herewith we quote part of a speech made in London by R. T. Bayliss, as chairman of the Exploration Company, on the occasion of the recent annual meeting of shareholders:

You will expect me to say something with regard to Mexico. It certainly calls for our first consideration, as it represents our largest and, unfortunately, has been for some years our most troublesome investment. From the economic point of view conditions in that Republic are little, if at all, better than they were twelve months ago. From the political standpoint they are about the same. Except in the Federal District of Mexico, which includes Mexico City, the Government seems unable to check, or control, the activities of the various bands of rebels, whose sporadic raids keep the outlying portions of the Republic in a condition of insecurity and unrest, and render the peaceful and regular operation of all industries impossible. Now this makes matters very difficult for our engineers engaged in local management, and exasperating for those who, like my colleagues and myself, are responsible to their shareholders for the profitable operation of mining properties in Mexico. We are not discouraged, however. We believe that more stable conditions of government must ensue before long, and we confidently expect that, when other circumstances permit, the governments of England and the United States will see to it that these chaotic conditions are brought to an end.

In spite of all these difficulties, our subsidiary companies in Mexico, with the exception of the Santa Rosa Mining Co., which so far we have been unable to re-start, have been working during the past year with more success than seemed probable at its commencement. The El Oro company, under the circumstances, and notwithstanding the added disadvantage of a very serious epidemic of influenza, has done well; and the Suchi Timber Co., allied thereto, has had a successful year. The Buena Tierra mine has had greater difficulties to contend with. After an enforced shut-down it re-started in May last and for three months did very well. Then the inadequate facilities for transportation furnished by the local railway, over which the ore is transported to the smelter, caused interruption in shipments.

Our investment of next importance, having regard to the sum involved, is represented by debenture and shareholdings of the Chile Copper and Greene-Cananea companies. Of the former I think I may say that the claims made by its promoters with regard to its capacity for production have been fully justified in the past year's work. The output for that period was 100,000,000 lb., or 50,000 short tons of copper. The reduction plant has been working in excess of the capacity for which it was designed, and it is anticipated that by the 1st of June this year the proposed extensions thereto will have been completed to an extent that will render possible a production at the rate of 160,000,000 lb. per annum as from that date. Further additions to the plant, it is added, are in contemplation and will be made as conditions warrant. Considering the difficulties this company has had to contend with during the War, these results, I submit, must be regarded as very satisfactory. The Greene-Cananea, although hampered in its operations, like all mines in Mexico, is perhaps today in better physical condition than at any time in the past, and produced roundly 53,000,000 lb. of copper during 1918.

The outlook of the copper market at the moment is somewhat difficult to gauge, owing to the large supplies left in the hands of all the Allies on the termination of hostilities in November, and to the consequent abrupt curtailment in the consumption of copper for military purposes. Some time must necessarily elapse before electrical, engineering, and other industries dependent upon copper as raw material, but diverted during the War to the manufacture of munitions, resume their normal consumption. So many difficult problems surround the question of industrial reconstruction that it may take some time for the consumers of copper to resume their pre-war activities. The stability of the copper market depends very largely on the period of such reconstruction, and also on the wisdom displayed in the disposal of the large surplus stock which undoubtedly exists. In the meantime drastic steps are being taken in the United States to restrict production, and I am of the belief that an equilibrium will be reached in supply and demand more quickly, perhaps, than at the moment seems probable. There is, moreover, one practical feature with regard to this accumulation which should not be overlooked. In normal times the stocks of copper in the hands of manufacturers and consumers throughout the world would represent a very large proportion of the present surplus, which today is held in very few hands; and, as a believer in the ultimate and general revival of trade, I do not therefore regard the present accumulation with alarm, or feel any uneasiness with respect to our investments in copper-mining companies.

I should like to add a few remarks concerning the outlook for gold mining. I have on past occasions mentioned to you the increasing difficulty in purchasing good gold mines at reasonable prices. This is mainly due to the fact that the known goldfields have been thoroughly explored, and there is not any immediate prospect of new mining districts becoming available for development. Until recently it was believed that the next big development would take place in Russia and Siberia, but for the time being that expectation must be deferred. Mexico, I am still convinced, offers the best field for investigation. Even so, the high rate of taxation already imposed makes it difficult to purchase mines on terms which will yield a satisfactory rate of profit to the investor after the payment of taxes assessed in that country and the further provision for income-tax payable on this side. During the War, moreover, and apparently for some time to come, the gold miner has been and will be, called upon to bear a very serious burden. In common with all other industries he has had to face largely increased costs; but, unlike such other industries, he has not been permitted to raise the selling price of his product, but has been compelled to dispose of it at the standard pre-war price of gold. Moreover, he has been obliged to accept payment therefor in a currency which has lost much of its purchasing value. Representations have been made by the producers of gold to the Treasury both in this country and in the United States, praying that they may receive some compensation for the exceptional hardship which has been imposed upon them, but there seems little encouragement for the hope that any relief will be granted. There is still another difficulty surrounding companies and individuals seeking mining enterprises abroad. The Treasury has announced its intention of maintaining the restrictions on new capital issues which prevailed during the War; and, while it may not absolutely prohibit all issues involving the investment of money abroad, the mere fact that the Treasury sanction must be obtained for this purpose adds to one's difficulty in negotiating the purchase of mines in alien countries. The outlook, therefore, for the gold-mine promoter and for companies such as this, which has rather specialized in gold mines, is not very encouraging, and it seems to us only the part of common sense and candor to recognize the fact.

While, therefore, we continue seeking for new mines, and are hopeful that we shall be successful in finding something we can confidently recommend to you, we feel it imperative to consider every or any description of business offered to us that may present favorable opportunities for investments of our funds. In pursuit of this policy we recently took an interest in the newly-formed British Metal Corporation, which undoubtedly starts with every prospect of becoming an important and successful institution, and, withal, will safeguard the non-ferrous metal industry within the British Empire. We have also acquired a substantial shareholding in the Burma Corporation. I feel very confident that the properties owned by that corporation will under its present exceptionally capable and prudent administration, prove to be one of the big and most successful enterprises of the world.

Labor Efficiency at Telluride, Colorado

The following notes are abstracted from the annual report of C. A. Chase, manager for the Liberty Bell Gold Mining Company.

The old productive areas in the mine [these had yielded 2,144,612 tons since 1899] were almost exhausted at the beginning of the financial year 1917-'18, but beyond the 4300-ft. east line there was a virgin area partly developed. Assays indicated ore of fair grade in a narrow vein. The section was completely equipped with hoisting, haulage, and air plant. Later on, the power supply failed, and much-needed skilled labor was lost from the mine.

Late in May a crisis was evident. More men could not be secured, and the competent men, long employed, were not working to capacity; in fact, an analysis showed that they were doing only as much per day as the shiftless wanderers. It is to be noted that on a day's pay basis of operating, both old men and new were paid equally. In this group of the skilled men, however, existed the capacity to make a production large enough to be profitable, and a study of individual records showed that, although they were doing no more per day, a few of them were doing a large part of the total work done because they were steady; for some reason they felt bound to work. This condition became a foundation stone, and the plan was devised to utilize their steadiness and then pay them on the contract system to work to capacity. The two classes of labor—mining and timbering—were consolidated in the contracts, doing away with interdependence. Beginning in June, the men were gradually weaned from distrust, and by August practically all work was on the new basis. The tabulation of special items for four months of approximately equal numbers of employees in mine illuminate the subject:

	Total mine shifts	Total tons stoped	Total square feet stoped
June	3,211	7,345	17,270
July	3,314	8,588	25,207
August	3,238	11,241	38,450
September	3,407	9,692	30,218

That area increased faster than tonnage, signifies a decrease in width of the vein and emphasizes the comparisons. Men working in adjacent and equal stopes, formerly paid alike, now earned severally, $3.50, $8, and $13 per day. The cost per ton fell, and the awste in the ore was less. Time to calculate precisely had been lacking and perhaps the contract rates were high, but too closely calculated rates would probably have found acceptance too slowly for the requirement. The number of men affected was about 15% of the total employees, but their work was the foundation on which profitable operation rested. The expedient was a reasonable success, and it was only regretted that other branches of the work could not be similarly benefited.

The great change in operating costs due to hardness of rock and narrow width of vein, in conjunction with high prices, is shown in the following comparative figures, per ton:

	Pre-war	1917	1918
Power	$0.092	$0.123	$0.220
Powder	0.100	0.175	0.520
Fuse and caps	0.014	0.042	0.077
Drill plant	0.055	0.075	0.234

THE mine-scale work of the U. S. Bureau of Standards is of special interest, in view of the need for maximum output of coal at the mines. Disputes over weighings cause strikes, loss of time, and reduced output. The Bureau experts were called upon, and they found conditions wholly unsatisfactory. In one case a 2-ton scale was 616 lb. in error against the miner. Improper installation, faulty methods of weighing and errors were corrected, and mines greatly improved. Indictments were found and fines imposed on the evidence. A general awakening and improvement resulted, and the prevention of strikes and the renewed satisfaction of the miner have gone far to maintain conditions favorable to a maximum output of coal.—Annual Report of Bureau of Standards.

REVIEW OF MINING

TORONTO, ONTARIO

New Railways to Aid Mining.—Kirkland Lake, Boston Creek, and Porcupine Notes.

Mining exploration in northern Ontario will be enhanced by the latest project of the Temiskaming & Northern Ontario Railway Commission. Kirkland Lake, where work has been considerably retarded by transportation difficulties, is to be connected with the T. & N. O. line by a 7-mile branch from Swastika. This line will draw its revenue almost wholly from mining. A 3-mile spur will be built from Timmins in the Porcupine area to Metagami, which will tap a fertile area suitable for agriculture. The proposal to continue the T. & N. O. line to James bay is under consideration. Prior to the War, considerable exploration was done along the proposed route, and will this year be continued by a party of geologists and surveyors, whose report will be awaited before the Government decisively commits itself to the project.

Kirkland Lake. H. H. Johnson, consulting engineer of the Kirkland Lake Proprietary, is at Kirkland Lake in connection with the proposed consolidation of the Tough-Oakes, Burnside, and Sylvanite properties, negotiations for which are stated to be making good progress.

The new 30-ton mill of the Burnside is now in regular operation.

A contract has been let for cross-cutting to cut the main vein of the Minaker-Kirkland at a depth of 125 ft., and for putting down the shaft to the 200-ft. level.

Boston Creek.—The plans of the Miller Independence have been altered. In place of driving an incline shaft on the vein to the 500-ft. level, a central vertical shaft will be sunk some distance south of the vein to a depth of 550 or 650 ft. and the vein reached by cross-cutting.

The first diamond-drill hole at the O'Donald has been completed, and results are officially stated to be highly encouraging.

At the Cullen-Renaud the shaft is being sunk to 150 ft. An electrically-driven plant will be installed.

Porcupine.—The Hollinger Consolidated has decided to erect additional and more powerful mining machinery at an outlay of $500,000.

The Davidson has contracted for extensive lateral work at the 500-ft. level. A cross-cut is being driven in the ore-body broken into by the shaft at the 460-ft. level to open a rich area indicated by diamond-drilling.

A syndicate from Butte, Montana, has taken over the Armstrong-Booth property and let a contract for extensive diamond-drilling.

CRIPPLE CREEK, COLORADO

Cresson Finds Rich Ore.—Three Good Discoveries in the Index Mine.—Strong Mine Leased.—Portland Shipments.—Dividends.

Gold production of the district in March was 74,643 tons of ore averaging $9.70 per ton.

A large body of ore has been entered in virgin ground at the 800-ft. level of the Cresson mine. A preliminary estimate gives a great value for the shoot. Mine samples have averaged $30 per ton as broken. The ore is believed to be the upward extension of the rich body opened at 1300 ft. two years ago, and later opened at 1000 ft. The management has planned a campaign of exploration of the area hitherto untouched.

Three important discoveries were made during March in the Index mine, on the south-western slope of Gold hill. The El Paso Extension company found ore at a depth of 1160 ft. at the junction of the main Index vein with a cross-vein. Samples at this point assay as high as 44.98 oz. gold. The ore is a basalt. On the fourth level, at a depth of 700 ft., the Beacon leasing company has opened ore on the Keystone vein, in the granite sill, extending south down Gold hill from the Midget mine. The vein, which is 3 ft. wide, is seamed with talc, itself almost filled with gold. Samples assayed up to 90 oz. Two cars—the first ore broken—one of coarse rock settled at $28, and a car of screenings at $57 per ton. None of the high-grade was included in this shipment. The third discovery was also made on No. 4, south on the Keystone vein by E. G. Fink, a lessee. The value here is as high as $67.

The Strong mine of the Strong Gold Mining Co., with a production exceeding $10,000,000, has been leased for the first time. Owen Roberts, well known in this district, is the lessee. He also was successful in a lease on the El Paso Gold King, in Poverty gulch, on the west side of the district.

Returns from the first 100 tons shipped from the recent discovery on the Roosevelt tunnel-level of the Portland settled at $58 per ton. This ore was mined at a depth of 2131 ft. In order to eliminate high freight and treatment rates on rich ore, this will be graded to 3 ounces.

The Modoc Consolidated has cut the upward extension of the new rich vein, first discovered north of the Last Dollar shaft, at a depth of 1200 ft., at the 1000-ft. level of the mine. The width and extent of the shoot at 1000 ft. has not been determined, but the gold content is 2 oz. The vein at 1200 ft. has widened to 20 ft. in about the centre of the shoot.

Production from the Nicholls shaft on the north end of the El Paso company's Beacon Hill estate will be resumed early in April. An electric hoist has been erected.

Dividends paid on the 10th of this month by the Cresson and Golden Cycle companies were $122,000 on $45,000, respectively. The Portland and Vindicator are also expected to pay quarterly dividends in April.

DURANGO, COLORADO

Power Shortage, Snowslides, and Railroads.

Silverton.—The outlook for ore production during the next two months is not promising. Owing to the dryness of last year, the Western Colorado Power Co. failed to secure sufficient water, with the result that reservoirs are getting low, and the local mines are not getting enough power. An early spring, causing rapid melting of the snow, may fill the reservoirs earlier than anticipated, which is during the latter part of April. This shortage affects operations of the Sunnyside M. & M. Co., most seriously, as the power now supplied is only sufficient to run the mine at two-thirds capacity, and the mill has been shut-down a week. If there is plenty of power at the time mentioned, the mill will resume operating about April 15, but the outlook is not very favorable. The Iowa-Tiger and Mayflower Leasing companies will also be obliged to curtail operations. The Gold King Leasing Co. will not be able to start a mill run until after June 1.

Snowslides are again causing trouble along the D. & R. G. branch from Durango to Silverton, and on the lines of the Silverton Northern. The former line was blocked for 6 days. All ore in transit has been stopped. Heavy sleet-storms accompanied the snow, resulting in added power troubles.

There is good foundation for the report that the Silverton Northern Railroad holdings have changed hands, and it should prove a great asset to the Sunnyside M. & M. Co., in view of the extensive developments in the Eureka district, to control this outlet for its ore. Reports from various sources indicate that the object of the U. S. S. R. & M. Co. in acquiring this property is to ensure an all-year round outlet for its product, by way of Ironton and Ouray to Salt Lake City. The distance from Ironton on the Silverton Northern to Ouray on the D. & R. G. is only eight miles, and would shorten the haul to Utah by 150 miles.

Telluride.—J. M. Belisle is mining and shipping carnotite ore, and has two carloads ready.

The power shortage mentioned will also affect operations in this district, although not as seriously as at Silverton, as the Smuggler Union company has its own power-plant, and is in a position to supply some power to the others in the district. Snowslides are recurring along the lines of the Rio Grande Southern, and ore is blocked at the present writing.

The heavy sleet resulted in the burning down of the transformer-house and the complete destruction of the transformer at the Iowa-Tiger. This will result in closing down the mill for at least a month, stopping concentration of not only the Iowa-Tiger ore, but also of the Mayflower, although the mines continue to operate and will probably ship some ore.

VICTORIA, BRITISH COLUMBIA

Ore-Testing Plants.—The Yukon.—Drilling in Kamloops.—New Development Contemplated in Scattered Regions.

The Dominion government is making provision in this year's estimates for the expenditure of $100,000 on one or more ore-testing laboratories in this Province. This is something for which British Columbian operators have been agitating for years. At present it is necessary to send ore for testing to Ottawa.

Klondike operators are preparing for extensive dredging and hydraulicking this year, according to reports from Dawson. Work will commence early in May. It is thought probable that the total gold output of $2,116,000 in 1918 will be considerably exceeded this season, as some of the larger companies, which have been tied-up by litigation and other matters, are planning to resume. It is estimated that 50 creeks of proved value remain in the Dawson district. The Canadian Klondyke Co.'s No. 4 dredge worked every day last winter and is going still, a remarkable feat under semi-Arctic conditions. The Mayo silver district is said to be opening encouragingly.

E. W. Parks, owner of a quicksilver mine in the Yukon, arrived from the north a few days ago and reported that a placer strike had been made above Marshall, a short distance beyond Holy Cross on the Yukon river. He states that he met a number of prospectors who have stampeded to the new diggings and that they report 50-cent pans as common. The creek on which these placer claims are situated, which ground is said already to be completely staked, runs into a slough of the Yukon river.

Four standard diamond-drill outfits have arrived at Thelia on the Kettle River Valley railroad, Kamloops district, and will be taken to the property of the Aspen Grove Amalgamated Mines, Ltd., for exploration purposes. Joseph Errington and associates are representing the bond-holders and extensive work is promised for the coming season. The property comprises 75 claims on which considerable work has been done.

Promising reports have been received from properties on Stone creek, 20 miles south of Prince George, where the Nechaco River Mines, a New York syndicate, has been carrying on development for two years. Its property is known as the Yellowjacket group. An assay from the quartz formation near the main lode returned $27 per ton in gold, silver, and lead. It is said that there are thousands of tons of similar formation on either side of the lode. The group lies four miles east of the Pacific Great Eastern railway grade and adjoins Stone Creek canyon. William West is in charge, but expects an engineer from New York to look over the ground and decide upon a plan of operations at an early date.

W. A. Phair, a pioneer placer miner of British Columbia, at present residing at Lillooet, offers a solution of unemployment for returned soldiers by their making a living from placer mining along the Fraser river.

The Echo Silver-Lead company, operating near Silverton, has entered the list of producers. Four cars of concentrate is produced monthly, containing 65% lead and 125 oz silver, and 40 to 45% zinc and 60 oz. silver. The latter product is being stored at the mill on account of the market The Echo mine is equipped with a two-bucket tram, connected with the Standard tram, by which ore is delivered to the latter's mill.

The manager of the Highland Valley Mining & Development Co., F. Keffer, states that its mine in the Ascroft district will be re-opened and probably placed on a producing basis this summer. The mine is well equipped, and has a concentrating mill.

The Committee of investigation into charges made by the Slocan lead-silver-zinc shippers against the Consolidated M & S. Co.'s smelting rates at Trail is reported to be making good progress, but it is not expected that the report will be ready before two or three months.

The Nugget-Motherlode-Searchlight claims on Sheep creek have been acquired by a British Columbian syndicate, which has been incorporated as the Nugget Gold Mines Ltd R. H. Stewart, well known in this Province, will supervise the work. A 10-stamp mill and cyanide plant is available.

The Portland Canal district, in the North-West, will be heard of more this summer, according to prospectors and others from that part. No one is more enthusiastic than R. W. Martin of Seattle, one of the owners of the Mineral Hill claims situated above the Bush mine, of which great things are expected this season.

The Mining Committee of the British Columbian Legislature has submitted a report declaring that the Taylor Engineering Co., which met with financial disaster during construction of a railway from the coast at Alice Arm to the Dolly Varden property, recently taken over by the Temiskaming Mining Co. of Ontario, is justly entitled to payment in full for the cost of the work done, plus 10% contractor's profit. It is asserted that the evidence shows that the contracting company had assurances that its investment in the road, beyond the originally estimated cost, would be repaid and that, reposing confidence in these assurances, it went forward to the limit of its financial ability. Therefore the Committee takes the position that the contracting company and its creditors should be fully protected before the Provincial Legislature consents to the renewal of the railroad charter.

THE MINING SUMMARY

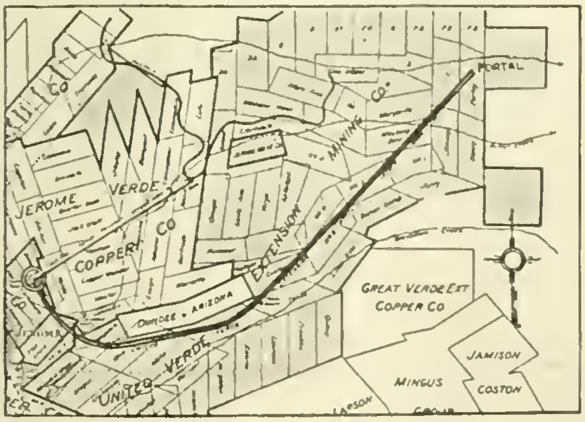
ARIZONA

Ajo. The New Cornelia company has developed an orebody on the southern claim, 400 ft. long by 260 ft. wide, carrying 4 to 9% copper. Underground work has been curtailed to two shifts per day with no Sunday work. Recent diamond-drilling done by the E. J. Longyear Co. has considerably increased the sulphide ore-reserve. The Regent and Silver Wing claims were recently acquired by the company from G. L. Ralston. In spite of decreased production and lowering of wages about 700 men are on the payroll.

Hackberry.—A group of claims on the Hackberry lode has been taken over by W. W. Lewis, who has incorporated tho Silver Bell Exploration Co. A tunnel is to be driven on the vein, which will pass at a considerable depth below the 100-ft. shaft.

The new 200-ton mill at the Hackberry mine is in operation. The recovery is about 85%. Sufficient ore has been opened for two years at full capacity of the mill.

Jerome.—The haulage-tunnel of the United Verde Extension has been holed through. Its length is 12,384 ft. In order to drain water in the mine, the last 300 ft. of the tunnel was of normal drift size, so now this has to be enlarged to full size 11 by 10½ feet.



PLAN SHOWING U. V. X. HAULAGE TUNNEL.

Kingman.—There is considerable activity at gold and silver properties around Chloride, Kingman, and Oatman. It is reported that the Amalgamated is to be in operation soon. The Adams company is unwatering its shaft. The Telluride M. & M. Co. has funds for further development. All of these companies are at Oatman. The Mossback mine, in the Silver Creek district, north of Oatman, is pushing development, and has recently opened a large quantity of milling ore. The company is to issue $400,000 of bonds to carry on work.

Patagonia.—Gross & Kennedy of Duluth, Minnesota, have taken an option on the American Boy and Hosey properties. A wagon-road is to be built to the former, and 300 ft. of shaft will be sunk in the latter.

Two shifts of miners are working at the El Paso mine of the Arizona Consolidated Copper Mines Co. The shaft has reached the 200-ft. level, and cross-cutting is being done at 150 ft. Development is also under way at the old Olive claim, which is yielding high-grade silver-lead ore.

Superior.—Magma Copper Co. produced 1,211,175 lb in February, an increase of 311,175 lb. over January.

Wickenburg.—The Empress Copper company, 18 miles from here, is doing nothing at present on account of the condition of the market. J. P. Hutchinson is manager

CALIFORNIA

The Inyo range, the Mount Whitney region, and Owens valley, which lies between these two ranges, in eastern California, are described in a report just issued by the U. S. Geological Survey, as Professional Paper 110, by Adolph Knopf. This region is off the main lines of travel and is not so well known as other parts of the State, but when the roads and railway facilities are improved, Owens valley, which affords the easiest access to the region, will certainly become famous for its magnificent scenery. The Sierra Nevada, which reaches its highest point in Mount Whitney, forms the west wall of Owens valley, and as it rises abruptly above the valley without intervening foothills the range displays its majestic height far more imposingly here than anywhere else along its course. The top of the Sierra Nevada is readily accessible by trails that start from the pleasant towns of Lone Pine, Independence, Big Pine, and Bishop. Good roads extend into the heart of the range from Bishop, the chief town in Owens valley, so that an automobile trip of hardly more than an hour will take the traveler to the headwaters of Bishop creek, whose profoundly glaciated canyons and spacious ampitheatres are among the most impressive in the entire range. The country west of the crest of this part of the Sierra Nevada is included in the proposed Roosevelt National Park.

The region is rich in mineral resources—silver, lead, zinc, tungsten, gold, and marble—and the waters of Owens lake yield soda and other chemicals. The mines at Cerro Gordo, in the Inyo range, have produced more silver-lead ore than any other mine in California, their output of base bullion between 1869 and 1877 amounting to $7,000,000. After those early flush times the mines long lay idle, but in recent years they have been re-opened, and Cerro Gordo has again become California's foremost producer of lead ore.

In 1913, large bodies of tungsten ore were discovered in the Tungsten hills, west of Bishop. They remained practically unknown until the spring of 1916, when outside interests bought them and began to develop them energetically. By midsummer, two mills had been completed and were in active operation, and the district has since supplied a large quantity of tungsten. Geologic conditions similar to those in the Tungsten hills prevail over a wide extent of country along the east slope of the Sierra Nevada. The places of contact of the intrusive granites with other rock, shown in the geologic maps accompanying the paper, are the most likely places to prospect for other similar bodies of tungsten ore.

Grass Valley.—The electric tramline, connecting the Empire and Pennsylvania mines, both under the same management, is under construction and will shortly be completed.

The road is a quarter-mile long and will be used to transport ore exclusively.

The Idaho-Maryland company is unwatering its shaft so as to explore the workings of the Eureka mine, closed for 50 years, after producing a great deal of gold.

Ingot.— Once more the Afterthought company has started its flotation plant. The treatment of the complex copper-zinc ore involves many problems.

Jackson.— Six carloads of carbonic acid gas in containers has been used at the Argonaut mine in an endeavor to put out the fire. The gas was sent underground through pipes.

Oroville.— A. F. Vogelsang, the First Assistant Secretary of the Interior, has reversed the Sacramento Land Office decision declaring mining land at Belden, on the north fork of the Feather river to be mineral bearing, and awarded the patent to Dr. and Mrs. P. F. Bullington of Chico. The action is based on the protest and contention of Gertrude Stewart that the land is agricultural and not mineral, and that she wants to make a homestead entry on the same. The order reversing the decision of the Land Office directs that a new hearing be conducted, to be confined, however, solely to the question of the character of the land. The case is of importance because of the fact that the Great Western Power Co., which proposes to construct a great hydro-electric plant in Butte valley, will need a right-of-way across the land in question for a railroad line to be built to the site of the power-plant. The right-of-way across these lands will be approximately a mile long.

San Francisco.— The State Mineralogist, Fletcher Hamilton, reports that the Secretary of the Interior announces that operators of chrome, manganese, pyrite, and tungsten mines may secure regulations and questionnaires for filing claims under the War Minerals Relief Act from the General Land Office, Customs House, San Francisco.

The attempted nullification of the present conservation law, providing for protection of Californian oil deposits, has been, in the main, rejected by the Senate Committee on oil. The State Mining Bureau, several months ago, called public attention to this attack. It was pointed out that the ultimate aim would be disguised under proposals that would leave merely the skeleton of an impotent law on the statute books; and would, furthermore, place its enforcement entirely in the hands of a few oil producers. The attack has already served a good purpose by bringing into public view a certain few large operators who have never recognized the interest of the public in the oil resources, and have obstructed reasonable enforcement of the law. The Senate Committee has reported the Rigdon bill out, minus some of its most destructive features, and has tabled the bill introduced by Senator J. R. Thompson of Santa Barbara, which proposed to make the present law thoroughly effective. As the Thompson bill is based upon correct governmental principles, it will continue to show the inadequacy of the present law. Due to its origin, the Rigdon bill (Senate Bill No. 199) still carries provisions that would, if enacted, lower the present standards of the State service and seriously interfere with and curtail constructive work, which the State officers are furnishing directly to the oil operators. A direct thrust at the foundation of successful supervision is contained in the proposal to remove the present legal requirements that the State officers both Supervisor and Deputies shall be technically trained as engineers or geologists. Past failures by both public and private concerns, aiming to develop and protect oil deposits, have hinged upon their ignoring the necessity for technical study and planning of underground work. All the large oil producers of California, with one single exception, now direct their field work by means of technically trained men. The standard of the State should be no lower than the highest found in private work. The return from the Army and Navy of young engineers, with oilfield experience, already ensures that there will be no scarcity of the necessary technical men.

The last weekly report of the California State Mining Bureau Department of Petroleum and Gas states that the Standard Oil Co., St. Helens Petroleum Co., General Petroleum Corporation, and Petroleum Midway Co. all filed notices this week to drill additional new wells in the Montebello field. Up to February 1, this field, which has occupied public attention for the past two years, has produced 8,700,051 bbl. of oil. This production does not come from a single stratum of sand. There are at least two separate and distinct zones of productive strata in the field. This fact has been determined by engineers of the Department from data obtained during development by companies operating in that field. As the public has not yet been supplied any correct information as to the underground condition of the field, some facts may be interesting. The first or upper oil-zone, which an occasional improvident operator has not desired to protect from water, has yielded 1,876,121 bbl. of oil and 121,332 bbl. of water up to February 1, through 19 wells that are known to produce from this zone alone. These figures do not include a number of wells that produce from both first and second zones. It is noteworthy that two of the 19 wells mentioned, neither of which was drilled in a manner approved by the Department, produced 99,859 bbl. of water, or 82% of all the water produced to date from the first oil-zone. All operators are now beginning to realize that the production of this upper zone of oil formations is a valuable asset. Under the guidance of engineers of the State Mining Bureau it has been demonstrated that by properly drilling and casing wells, so as not only to exclude top waters but also the so-called intermediate waters, which appear to exist at depths slightly greater than 550 ft. below the top of the first oil-sand, all the oil measures will be protected from water and the greatest possible production obtained. The total production of oil from the second oil-zone to February 1, is 6,823,930 bbl. Three wells alone in the Montebello field produced 410,201 bbl. of water out of a total water production of 648,361 bbl. It is gratifying to note that the company operating the largest water producer, in this trio of offenders, is now taking steps to remedy this condition.

Sonora.—The If-I-Can gravel mine is reported to have been sold last week by O. B. Lefurgy of Oakland to L. R. Davis of Salt Lake City and R. Wallace of San Francisco, acting for others. The price was $25,000 cash. The property is 12 miles from Jamestown. It has been opened by a 1500-ft. bedrock tunnel. A disintegrating mill had a capacity of 130 tons per 24 hours.

COLORADO

Boulder.— Silver will be produced in large quantities from Boulder county this year, according to the 'Miner', as the Caribou, Congo Chief, Up-to-Date, Victoria, White Raven, and Yellow Tiger mines are all showing rich ore. While the tungsten industry here is practically at a standstill, the mining of silver will help make good the deficiency.

Breckenridge.— The Wellington Mines Co. in 1918 received $735,640 for lead-zinc ore sold. The profit was $386,319. Dividends absorbed $300,000, and now total $1,850,000. C. M. Henderson is in charge.

Leadville.— In spite of the high price of silver there are said to be a number of good mines idle in this district.

IDAHO

The U. S. Geological Survey has recently issued, as Bulletin 680, a report by A. R. Schultz, describing the coalfields of the Bighole mountains and other districts in Teton county, Idaho, and the adjacent part of Wyoming. The report also describes extensive phosphate deposits in the same general region. The existence of these deposits has been known for more than ten years, but their extent was not known until they were mapped in detail and sampled by Mr. Schultz.

Boise.—The governor, D W Davis, has signed House Bill No 46, thereby creating a Bureau of Mines and Geology The initial appropriation for two years is $30,000, plus $25,000 for co-operation with the U S Bureau of Mines and Geological Survey The board of control is vested in the Governor, J. J Day, D C Livingston, R N Bell, and F A. Thomson.

Hailey.—The Mascot M & M Co has been driving its lower tunnel all winter, and is in 148 ft This will eventuall cut the veins at a depth of 700 ft The ore carries lead and silver. A mill is contemplated Charles Peter is general manager

Mullan.—The Idaho-Carbonate Hill has $60,000 available and is to resume work in May, according to the president, W D. Greenough So far, $123,000 has been spent since the consolidation About 2000 ft. of driving and sinking from 450 to 800 ft is contemplated. The ore carries lead and silver.

The Consolidated Interstate-Callahan reports a loss of $195,933 for 1918, this after paying $456,222 in dividends The operating profit was $291,938. Supplies advanced nearly 100% in cost.

Wallace.—The Hecla Mining Co. in 1918 shipped 15,133 tons of crude ore and milled 309,656 tons. This yielded 51,365,676 lb of lead, 133,341 lb. of zinc, and 1,590,062 lb of silver The net profit was $2,054,716, of which $350,000 was paid in dividends. Ore-reserves total 1,581,115 tons

MICHIGAN

Houghton.—Mohawk made a profit of $1,003,690 in 1918, compared with $1,971,601 in 1917 The output was 10,781,041 lb of copper, a decrease of 1,500,000 lb Costs totaled 14.641 cents, an increase of 2.58 cents.

Mohawk pays $1 per share on May 1 This is half of the previous quarterly distribution

The Mohawk is to spend $40,000 for the tunnel under the Lake at the stamp-mill at Gay before it is completed. The work is ambitious, but is more than justified by the circumstances, and is more than warranted. The tunnel is now in 600 ft., going forward at the rate of 15 ft per day. The shaft was sunk 125 ft., and the tunnel is 100 ft. under water all the way out. It is in sandstone most of the distance. It will go out 2200 ft., and from soundings at that point in the Lake there will be 30 ft. of water overhead and 50 ft. of rock. If conditions warrant, it is possible that the tunnel will go out 2600 ft., at which point there will be 44 ft. of rock and 33 ft. of water. The purpose of the tunnel is to provide water for the mill. Three electric pumps, each with a capacity of 7,000,000 gal. per day, operated by a 1250-kw. turbine, have been ordered. The excess electric power will be used for re-grinding, which may be part of the process at this mill. Experiments are now being conducted along these lines.

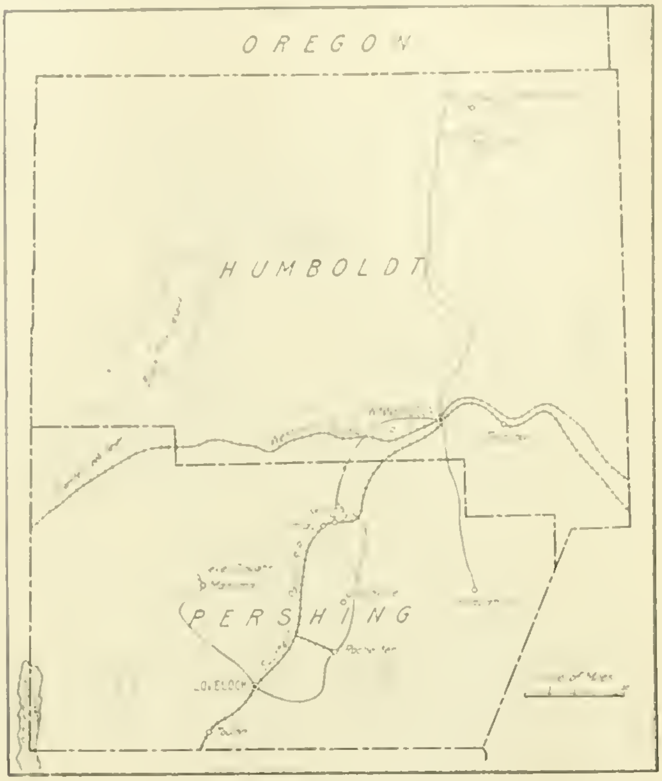
The Mayflower-Old Colony Copper Co. has levied an assessment of 50 cents per share, due on April 15. This is the second since the consolidation two years ago. The new shaft is down 1050 ft., and sinking continues with plenty of skilled men.

Calumet & Hecla in 1918 made a net profit of $4,349,196, after reserving $600,000 for federal taxes. This is about half of the profit for 1917. Dividends amounted to $55 per share. The output from 2,876,392 tons of ore was 58,722,969 lb., a decrease of 10,000,000 lb. Costs were 21.05 cents, an increase of 8.04 cents per pound.

The report of the Naumkeag Copper Company for 1918 shows that 997 ft. of driving and 617 ft. of sinking was accomplished The incline shaft was deepened to 1027 ft. Work on the 400-ft. level was generally unsatisfactory, only a small 'local' shoot being found The lode was passed by the shaft at 975 ft. About 500 ft. of work was done on the 1000-ft. level, but less satisfactory than at 400 ft., so work was stopped, and transferred to the south part of the adit-level, where it is now in progress. Cash on hand totals $28,126 J H Reeder is superintendent

NEVADA

Carson. The State Legislature has voted to divide Humboldt county, the new territory being named Pershing county. The accompanying map shows the partition, also the principal mining centres therein.



PART OF NEVADA SHOWING HOW THE ORIGINAL HUMBOLDT COUNTY WAS SUBDIVIDED.

On April 1, Governor Emmet D. Boyle vetoed A. B. No. 175 "an Act to amend an Act entitled 'An Act creating the Nevada State Bureau of Mines and prescribing it duties'."

Divide.—The Nye county commissioners have approved of the townsite, and town lots are on sale. A corner lot, 80 by 50 ft., sold for $250. The authorities at Washington have been asked to arrange for a post-office.

Jarbidge.—In 1916, I. W. Anderson of Tacoma obtained leases and options to purchase several groups of lode claims for Spokane capitalists. Later, there was organized the Jarbidge Mines Co., under the laws of the State of Washington, to operate La Veta group of 8 claims, which had been purchased for cash. This and the other claims are situated high up on the west slope of the Crater range or Jarbidge mountains, at an elevation of 8300 to 10,300 ft. The properties cover the mountain at the heads of Bonanza, Gorge, and Snowslide gulches. Work was started on the group and some money paid on the purchase-price. Some of the important veins of the Jarbidge district are found within these areas. The management of the Jarbidge Mines Co. is generally believed to have spent $30,000, when war suspended activities. The company is expected to resume as soon as financial conditions approach normal.

Thompson. Mason Valley Copper Co produced 947,336 lb in February, against 1,111,000 lb in January.

MISSOURI

Joplin.—Mine-owners in the Tri-State region are to ask co-operation of retail dealers so that the cost of living may be reduced. Wages have been cut somewhat, but war prices for food still hold.

Production of the region last week was:

State	Blende, tons	Calamine, tons	Lead, tons	Value
Kansas	1,010	...	324	$71,899
Missouri	1,447	146	390	84,215
Oklahoma	7,651	...	1,248	366,866
Total	10,108	146	1,862	$525,980
Average value...	$37.50	$26	$60	......

The total value was $84,000 more than the previous week.

There are now 123 concentrating plants in operation in this region, six new ones being started last week. The total capacity is 10,000 tons of zinc-lead concentrate per week.

MONTANA

Butte.— Davis-Daly in February produced 291,624 lb. of copper and 10,848 oz. of silver, compared with 1,018,889 lb. and 39,093 oz. in January.

Anaconda has suspended work at the East Gray Rock, Silver Bow, and Butte-Alex Scott shafts. The last named mine will be operated through the West Colusa while the Scott shaft is being fire-proofed. The other two shafts are also to be fire-proofed. The daily tonnage of ore will be reduced by 900 thereby.

OKLAHOMA

Picher.—The Miami Wonder Mining Co., through its president, F. D. Whiting, has adopted a profit-sharing system for its employees.

At the Mahutska, controlled by the R. Y. Ramage interests, the mill dressed 1300 tons of 'dirt' in 70 hours last week, yielding 185 tons of lead and 99 tons of zinc concentrates. The ore averaged 10.77% lead and 6.07% blende recovered. W. L. Kepner is superintendent.

TEXAS

O'Donnell.—J. W. McRea and associates are constructing here the first unit of a plant for the separation of potash, epsom salt, and borax from material obtained from the beds of two large basins or lakes, eight miles west of O'Donnell. It is stated that the soil for a depth of 6½ ft. is highly impregnated with these products. Each lake is five miles in area. C. H. Doak, postmaster here, who has been making investigations of possible potash deposits in this section of western Texas for some time past, located the dry lakes and brought them to the attention of McRea.

Wichita Falls.—According to the 'Wichita Oil Reporter', the average daily output of oil in this State is 210,000 bbl. Of this, Wichita contributes 70,000 bbl., Ranger 70,000 bbl., and the remainder from southern Texas and the Gulf coast. It is said by some that labor is scarce in the Ranger field, while others report the reverse. Wages are from $4.50 to $12 per day.

UTAH

Eureka.—The new railway into the eastern end of the Tintic district is now being built by the Utah Construction Co. The length, including spurs, will be 11 miles, and the cost $300,000. Completion is expected by August.

Salt Lake City.—Dividends paid by companies in this State since January 1 total $2,995,398, as follows: Bingham Mines, $37,500; Chief Consolidated, $110,530; Daly, $27,000; Eagle & Blue Bell, $44,657; Iron Blossom, $25,000; Judge, $60,000; Ontario, $75,000; Tintic Standard, $93,976; Utah Consolidated, $75,000; and Utah Copper, $2,436,735.

Tintic. The Tintic Milling Co., G. H. Dern, manager, is considering the erection of a cyanide plant to extract the gold from the ores offered for treatment. Regular shipments of bullion are made.

In Professional Paper 107 of the U. S. Geological Survey, the geology and ore deposits of the Tintic district are discussed in 282 pages by Waldemar Lindgren, G. F Loughlin, and V C Heikes

WASHINGTON

Boyds.—The Napoleon mine of the Canada Copper Corporation in Ferry county has been closed. The 5000-ft. Bleichert aerial tram has been moved to the Mountain Chief mine at Roneta.

Spokane.—Dividends paid by companies in the Northwest during the first quarter of 1919 totaled $1,484,711, compared with $2,629,307 in that period of 1917. Idaho contributed $765,150, less than half of the previous amount; British Columbia, $695,711, nearly up to the mark; and Washington, $23,790, an increase of this sum.

CANADA

British Columbia

Ainsworth.—The Florence company is operating its mill 24 hours daily now. The monthly output of concentrate is expected to be 600 tons, assaying 70% lead and 24 oz. of silver. A Richards-Janney classifier and flotation plant recently added will recover an extra 10%.

Anyox.—The Granby Consolidated expected to blow-in its furnaces early in April.

Trail.—Ore received at the Consolidated M. & S. plant here during the third week in March totaled 8208 tons, an increase of 662 tons over the second week. The Centre Star at Rossland sent 2748 tons and the Sullivan 3970 tons.

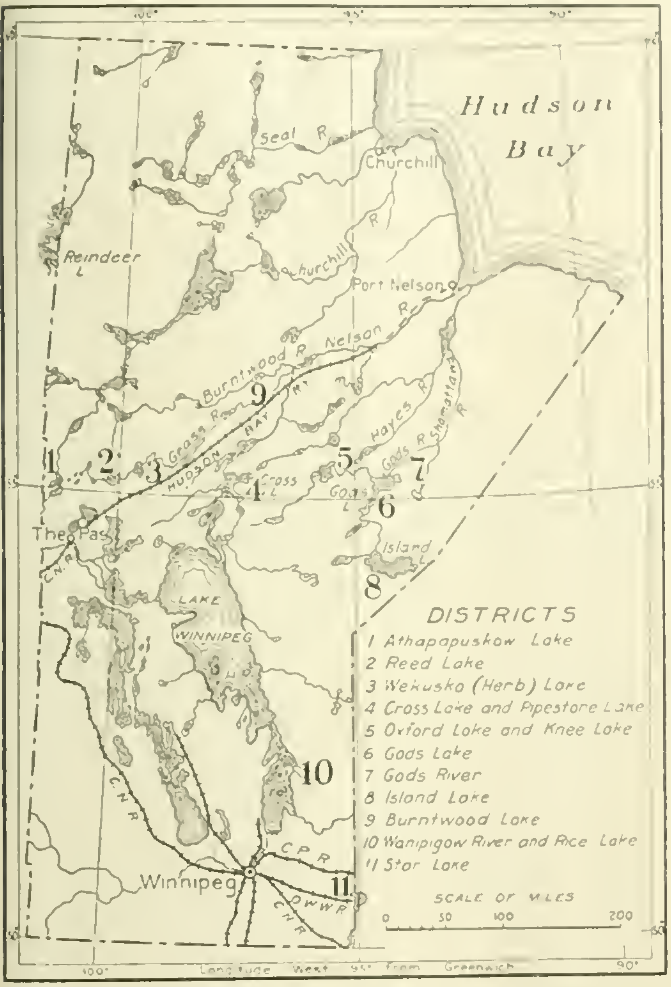
Manitoba

The Pas.—According to R. C. Wallace, in the March Bulletin of the Canadian Mining Institute, the Mandy Mining Co. in 1918 shipped to Trail, B. C., 6000 tons of ore carrying 20% copper, 0.1 oz. gold, and 2.5 oz. silver, worth a total of $651,000. In 1917 the output was 3300 tons, valued at $274,560.

The late commissioner of northern Manitoba, J. A. Campbell, has had published a 52-page illustrated bulletin on Manitoba's Northland, including the Hudson Bay region and the Rice Lake gold area. The first article is 'Prospecting Areas in Manitoba', by E. L. Bruce of the Dominion Geological Survey. The accompanying map shows the known districts. 'The Northern Manitoba Mineral Belt' is the title of a report by Mr. Campbell, who also writes on 'Northern Copper Country Development'. M. C. Hendry of Winnipeg describes the 'Water-Power Resources of Manitoba', while C. A. Bramble covers 'The Rice Lake Gold Area', where several mines are being developed. The geologic features of Rice Lake are briefly discussed by R. C. Wallace and J. S DeLury of the University of Manitoba. The natural resources of the region are great, including fish, fur, game, timber, and minerals. Those interested should secure a copy of this general review of northern Manitoba.

The manager of the Flin-Flon Syndicate, John Black, and John Hammel of the original owners, with R. C. Wallace and J. A. Campbell, of The Pas, formed a part of the Western delegation that recently waited upon the Government with reference to railway development in Manitoba. President Hanna, of the National Railways, received the delegates at Toronto, and after hearing their representations, he pledged to do the following railway construction:

Flin-Flon Railway—If the owners of the ore deposits there will guarantee to erect a smelter with a capacity of at least 2000 tons per day, the railway will be built from The Pas forthwith. The syndicate owning this ore has the matter in hand, and it is expected that it will agree to the erection of the works. It rests upon them whether the mineral fields of Manitoba will be opened this year. — Melfort-The Pas railway—Mr. Hanna assured the delegates that this line would be partly constructed this year. Work would commence at Melfort, and up the Carrot valley for a distance of 30 or 40 miles. Grading only would be done this year, the rails laid down next year. The Vonda spur to Melfort will have 20 miles of steel laid this year. With the Carrot River line this will give direct connection with the Hudson Bay railway and The Pas. The Melfort-Saskatoon-Humboldt road from Breux to Humboldt will be completed this year. The Estevan and Souris delegates were told that a line was contemplated from west of Moose mountain to the Hudson Bay railway. The deputation also asked that Sturgis on the Thunder Hill line be connected up with the Hudson Bay railway. Assurance was given that half of this work would be done this year. All told, six lines projecting toward The Pas, to connect with the Hudson Bay railway, were favorably dealt with. Two more, one, the Flin-Flon road, are nearer realization than thought possible a week ago. The C. P. R. is reported to have surveyors out running a line west to The Pas, through the Carrot River valley toward Athapapuskow Lake region. These two bring the total up to eight railways pointing north.



PART OF MANITOBA, SHOWING MINERAL DISTRICTS.

Ontario

Porcupine.—The McIntyre-Porcupine company disburses 5%, or $180,514, on April 15. This makes $1,263,599 to date. The present monthly gold yield is $140,000.

PERSONAL

Note. The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

F. W. Bunyan is in San Francisco.

J. B. Tyrrell was at Porcupine last week.

E. H. Nutter has returned from Washington.

H. N. Lawrie, of Portland, Oregon, is visiting San Francisco.

David T. Day, of the Geological Survey, was in San Francisco last week.

L. O. Howard has returned to Salt Lake City after a visit to El Paso, Texas.

T. M. Hamilton has left Santiago, Chile, and is now at Lewistown, Montana.

J. H. Mackenzie was at Divide, Nevada, last week, accompanied by **George Wingfield**.

P. R. Middleton, of Sydney, Australia, arrived in San Francisco on the 'Ventura', on his way to Salt Lake City.

Clyde Marsh, mechanical engineer at the Northport smelter, at Northport, Idaho, has been discharged from the Navy.

Thos. M. Miller, who served as First Lieutenant with the British Tank Corps for 13 months, in France, has returned to Berkeley.

E. P. Mathewson, director of the A. S. & R., passed through San Francisco on his way from El Paso to Tacoma, on a tour of inspection.

William W. Logan is leaving for Alaska this week to take charge of the cyanide plant of the Gold Bullion Mining Company, at Willow Creek.

W. J. Rose and **H. Warlow Davies**, of Broken Hill, Australia, are visiting Butte, Montana; they will also go to Trail, British Columbia.

J. E. Johnson, Jr. of New York, was killed in an automobile accident on April 5. Details will be published in our next issue.

The United States Potash Association was formed at Denver last week. T. W. Boyer of Salt Lake City was appointed president; A. C. Harrington of New York, vice-president and treasurer; and T. E. Evans of Omaha, second vice-president. Other members of the directorate are L. A. Cover of Baltimore, F. M. Edgell of Denver, W. E. Richardson of Central City, Nebraska, and T. J. Stewart of New York.

The fourth annual meeting of the American Association of Petroleum Geologists was held at Dallas, Texas, on March 13 to 15. More than 200 petroleum geologists and others were present. David White, of the U. S. Geological Survey, I. C. White, State Geologist of West Virginia, Ralph Arnold, valuation expert of the Internal Revenue Department of the U. S. Treasury, and Charles Schuchert, professor at Yale University, participated.

The U. S. Civil Service Commission announces an open competitive examination for mining engineer for metal and mineral investigations, on May 6, 1919. The register of eligibles will be divided into three grades, as follows: (1) $1800 to $2400; (2) $2400 to $3000; and (3) $3000 to $4000 per year. The entrance salary within the range stated for each grade will depend upon the qualifications of the appointee and the importance of the duty to which he is assigned. Competitors will not be required to report at any place, but will be rated on the following subjects, which will have the relative weights indicated: (1) education and experience, 80; and (2) publications, reports, or essay (to be filed with application), 20.

THE METAL MARKET

METAL PRICES

San Francisco, April 8

Aluminum-dust, cents per lb.	60.00
Antimony, cents per pound	8.00
Copper, electrolytic, cents per pound, in carload lots	15.50
Lead, pig, cents per pound	5.50— 6.50
Platinum, per ounce	$100
Quicksilver, per flask of 75 lb.	$67.50
Spelter, cents per pound	8.00
Zinc-dust, cents per pound	12.50

EASTERN METAL MARKET

(By wire from New York)

April 8.—Copper is dull though steady. Lead is quiet and firm. Spelter is inactive but steady.

SILVER

Below are given official (not Government) quotations, in cents per ounce, of silver 999 fine. In order to make prompt settlements with smelters and brokers, producers allow a discount from the maximum fixed price of \$1.01½, hence the lower price. The Government has not fixed the general market price at \$1 but will pay this price (as from April 23, 1918) for all silver purchased by it. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange. On August 15, 1918, the Treasury announced that the maximum price was fixed at \$1.01½ per ounce. The British government fixed it maximum at 49½ pence, on September 2, but on November 12 this was changed to 48¾, on December 13 to 48 7/16, and on February 20 to 47¾ pence. On March 25, on account of the low rate of exchange, the London price was adjusted, with a minimum of 95 cents, resulting in daily fluctuations.

Writing from London on March 13, Samuel Montagu & Co. said that the absorption of sovereigns (gold) in India during the year 1917-'18 amounted to 1166 lacs of rupees (\$37,312,000). The difficulties in providing sufficient silver to reinforce the silver balances, impelled the Government to release sovereigns for currency between April and August 1917, and in February and March 1918, principally in connection with Government purchases of wheat. The Government currency report, however, stated that the bulk of these sovereigns found their way shortly after issue to Bombay and Calcutta, where they were mostly turned into jewelry. According to the 'Times' of London on March 6, private advices suggest that India may be on the verge of a worse food famine than the visitation of 1900. There is also a grave fodder famine, which is said to be resulting in a wholesale loss of cattle, just as the herds of Gujerat were all but wiped out 18 years ago. Eastern banks do not appear to take so grave a view of the situation as outlined above, but should these forebodings be realized, the remarkable cumulative prosperity of India may be revealed by the putting into circulation of some of the vast number of silver rupees hoarded since the year of famine indicated above.

Silver produced by the U. S. S. R. & M. Co. in 1918 amounted to 15,337,465 oz., 2,337,000 oz. more than in 1917, and 3,700,000 oz. more than in 1916. Most of this comes from Mexico.

Silver sold by the Calumet & Hecla company in 1918 amounted to \$238,368, a by-product of copper.

Copper sales during the first three months of 1919 were only about 110,000,000 lb., compared with a refinery output of probably three times that quantity.

Brass companies, which normally consume the bulk of the copper output, are operating at 30% capacity with few orders on their books.

Dividends paid by copper companies during the first quarter of 1918 totaled \$22,384,329, compared with \$38,645,042, \$15,341,307, and \$20,537,100 in the same period of the previous years.

Lead on hand at the Trail, B. C., smelter, amounted to 8266 tons on March 1, against 9042 tons on February 1.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound:

Date			Average week ending		
Apr.	2	6.55	Feb.	25	6.69
"	3	6.55	Mch.	4	6.61
"	4	6.60	"	11	6.55
"	5	6.60	"	18	6.50
"	6 Sunday		"	25	6.48
"	7	6.65	Apr.	1	6.53
"	8	6.65	"	8	6.60

Monthly averages

	1917	1918	1919		1917	1918	1919
Jan.	9.75	7.78	7.44	July	8.98	8.72	....

May	9.41	7.29	....	Nov.	7.76	8.75	....
June	9.63	7.02	....	Dec.	7.84	8.40	....

Zinc ore prices slumped \$2.50 per ton to \$37.50, basis 60% metal at Joplin last week. The weak spelter market is the cause. It is said that it is costing \$30 per ton to make concentrate at present.

The American Zinc, Lead & Smelting Co. in 1918 made a profit of only \$911,115, one-half of that in 1917, and one-tenth of that in 1916. The average price of spelter in those three years was 7.89, 8.73, and 12.63 cents per pound.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Date					
Mch.	11	75.00	Mch.	25	68.00
"	18	68.00	Apr.	1	68.00

TIN

Prices in New York, in cents per pound. The monthly averages in 1918 are nominal. On December 3 the War Industries Board fixed the price to consumers and jobbers at 72½c. f.o.b. Chicago and Eastern points, and 71½c. on the Pacific Coast. This will continue until the U. S. Steel Products Co.'s stock is consumed.

Eastern Metal Market

New York, April 2.

Firmness characterizes all the markets, with an optimistic tone in most cases.

Antimony is unchanged

Copper sales have been fairly heavy, and prices have gradually advanced.

Lead is firm again with a better demand.

Tin is still stagnant and devoid of features

Zinc is still lifeless, but the tone of the market is better with prices slightly firmer

ANTIMONY

Quotations are nominally unchanged at 6.25 to 6.37½c., New York, duty paid, for Asiatic grades. Demand is light.

ALUMINUM

No. 1 virgin metal, 98 to 99%, is obtainable at the nominal quotation of 28 to 30c. per lb., New York, with re-melt metal of the same analysis 2c. per lb under this.

COPPER

There is now no question but that the turn has come in the copper market. In March there was more buying than in any month since the armistice, and prices have gradually risen since the low point a few weeks ago. It is the opinion of many that those levels will not be reached again, even though a slight recession may be possible any time. As an indication of the position, one large producer told the writer yesterday that his company had done a splendid business in March, mostly all for April delivery, and that the volume was close to a normal turnover. Some estimates place the total sales in March at 75,000,000 lb., with nearly half of this sold last week. Demand continues good, and the market may be characterized as firm and steady, with the tendency upward. Electrolytic copper is quoted at 15.37½c., New York, for April delivery, with Lake copper largely nominal at 15.62½c., New York. Trading in copper on the New York Metal Exchange was started on Monday, March 31, and reports are that it was a successful and satisfactory inauguration of this new movement. A feature of it was the high prices bid, especially for future delivery, running up to 15.75c. for July shipment. No sales were reported on that day, but yesterday sales were made of 100 tons of electrolytic at 15.50c. for April delivery and 25 tons at 15.65c. for June. The report of the representatives of the Copper Export Association, who just returned from Europe, is not especially bullish, at least not so far as the immediate market is concerned. They say that stocks in the hands of the Allied governments are rapidly being depleted, and that consumers are not well supplied; also that Germany is bare of copper and buying from all these sources should be pronounced when peace is effected, or soon after. An unconfirmed rumor is to the effect that the export price of the Association is now 18c. per lb., New York, instead of 23 cents.

IRON AND STEEL

Little in the shape of a broadening demand has appeared in the second week of the new prices. Practically all the business offered is still recognized as having been held back awaiting the reduction in prices. The Railroad Administration's refusal to accept the new steel prices as arranged by the Industrial Board, or to be bound by those yet to be fixed on coal and other material, seriously threatens the whole program of stabilizing prices. The railroads would nominally buy over 25% of the country's output of coal and 20% of the steel production. The railroad authorities may yet be brought into line by Presidential pressure. Export inquiries are numerous, but so far little business has resulted. Heavy melting steel scrap, which last week fell so low that open-hearth steel plants started to use larger quantities, has advanced because of this and is now $2 or more per ton above the low point.

LEAD

All the cheaper lots of lead that were being offered a week or so ago have been apparently absorbed or withdrawn, and the market is firmer at 5.25c, New York, or 5c., St. Louis, for both the outside and the Trust. Inquiry is better than in the last two or three weeks, and the tone of the market is decidedly firm. There have been sales in fact of two fairly large quantities, and it is believed that the demand will improve from now on.

TIN

Instead of becoming less restricted the market has become more so. Those in authority have requested American tin smelters to cease selling their product until the allocated metal has been absorbed, or at least until further notice. This they have agreed to do, and American tin is practically unobtainable. Spot Straits tin is still obtainable only at the fixed price of 72.50c. per lb., New York. A Government statement is to the effect that stocks of tin in the United States on March 1 were about 20,000 tons, and that consumption was at the rate of about 3500 tons per month. Tin arrivals in March were 2070 tons, of which 1975 tons came in at Pacific ports. Stocks and landing on March 31 were 156 tons. Imports in the first quarter were 6341 tons, compared with 12,828 tons in the same quarter in 1918. The London market for spot Straits yesterday was £226 15s. per ton.

ZINC

Despite the fact that demand has not broadened, the market may be termed as firm and steady, with quotations slightly higher than a week ago. Prime Western for early or most any delivery is held at 6.20c., St. Louis, or 6.55c., New York. There has been some buying as well as inquiry from the galvanizing interests, but this has not been large. The hope is still strong that it will be larger as the weeks advance. There is almost no demand from brass-makers. There is little export demand. It is expected that the Government stocks of zinc, mostly high-grade, will be disposed of by a special arrangement similar to that of copper.

ORES

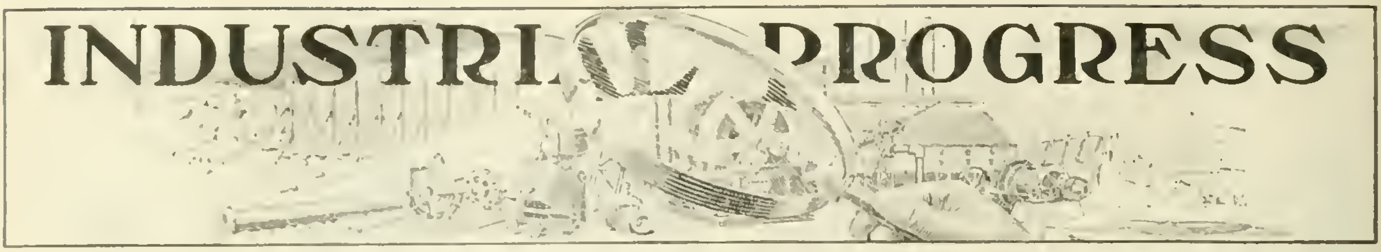
Manganese: Imports of high-grade ore in February are officially reported as 20,819 long tons. An interesting fact is that, of the January imports of ore 47,000 tons, over 14,000 tons came from Cuba.

Manganese Iron Alloys: Certain British producers are again offering their standard 80% alloy in the American market and are asking $150, seaboard. All import restrictions have just been removed. The British price compares with $150 delivered for the American 78 to 82% alloy, with $2 per unit deducted for each percentage under 78, making the 70% alloy $134 delivered. Spiegel is quoted at $40, freight allowed, for the 16 to 19% alloy, with $45 asked for the higher analysis.

Molybdenum: Prices continue nominal and unchanged at 80 to 85c. per pound. Exports of molybdenite are reported as good.

Tungsten: Only one mine is reported as operating in the United States. Foreign mines are also working on short time, if at all. These facts are regarded as the only hopeful phase of the situation, because stocks will soon be depleted.

INDUSTRIAL PROGRESS



INFORMATION FURNISHED BY MANUFACTURERS

DISPOSAL OF MATERIAL BY AIRCRAFT BUREAU

Plans for the disposal of surplus material now in the possession of the U. S. Bureau of Aircraft Production, or which is being taken over by this Bureau upon settlement of contracts with manufacturers, have been completed, and the organization for carrying out the details is rapidly being perfected. The primary consideration in these plans, which have been matured under the general policies as laid down by the Director of Sales of the War Department, has been the prevention of any disruption of the market and as full and complete protection of the Nation's industries as possible, as the following outline will show:

There has been formed a Material Disposal Section of the Bureau, organized on a basis similar to that followed by large commercial houses that handle sales through branch offices. This Section will be under the direction of First-Lieutenant Charles S. Shotwell. Sales will be made under the supervision of a sales manager stationed at Washington. The Bureau will probably have for sale the following material, and as soon as this has been established as surplus and policy for the sale of same determined, the Bureau will issue bulletins covering the material for sale.

b—1 Machine tools and fixtures
b—2 Electric machinery
b—3 Dies, tools, jigs, and gauges
b—4 Chemicals, paints, and oils
b—5 Metals
b—6 Motor accessories
b—7 Lumber
b— 8 Hardware
b— 9 buildings and lands
b—10 Fabrics
b—11 Scrap
b—12 Shop equipment
b—13 Office equipment
b—14 Miscellaneous

Sales negotiations will be handled by salesmen in each of eight district branches, to be at Boston, Buffalo, Chicago, Dayton, Detroit, New York, Pittsburgh, and San Francisco. These salesmen will be authorized to make sales of property wherever located, after the same has been cleared by the Board of Sales Review of the office of the Director of Sales, so that the prospective buyers will communicate with the branch office in the city nearest them. This arrangement, it is expected, will make it possible for manufacturers needing machinery and supplies to purchase conveniently and at fair prices. The salesmen will have full authority to sell at the best offer made, provided that offer is at or above an appraised value arrived at independently, or at market-value in the case of raw material.

Bulletins containing full descriptions of material for sale will be issued from time to time, and be kept up to date. Those interested will be placed on the mailing-list upon request addressed to the Bureau of Aircraft Production, Material Disposal Section, Washington, D. C. To save delay requests should specify the commodities on which information is desired by reference to the sales classification.

INCREASE IN FILTER PRODUCTION

The following table, prepared by the Oliver Continuous Filter Co. of San Francisco, shows the growth of its export business during the last five years. In spite of export restrictions the Oliver output advanced each year. Prior to 1914 the business with Mexico was larger than in 1916, and from present indications it will advance again. A recent order was for $40,000 of cyanide equipment. Most of the Mexican business of late years was with the northern copper companies. The shipment to India was to the Burma Corporation, and that to Siberia to the Irtysh Corporation. Filters in Chile were principally for the nitrate industry, from which a big demand for the Oliver is expected.

COMMERCIAL PARAGRAPHS

A handsome 64-page catalogue dealing with its chlorine control apparatus has been sent us by the **California Jewell Filter Co.**, Merchants Exchange, San Francisco.

An 8-page leaflet of the **Troy Wagon Works Co.** of Troy, Ohio, gives a list of 209 users of its trailers with 86 makes of motor-trucks, used in congested cities and in country hauling.

Pratt-Gilbert Company, of Phoenix, Ariz., has just received an order for ITP carbide mine lamps from **T. Knight Bayne**, Victoria, B. C. This firm is building up a large trade in the West through the merits of the lamp and the quick service made possible by carrying a very large stock.

If you wish to fasten a step or handle to a concrete or brick wall, tighten a loose screw-driver handle, tighten the handle of a hammer, need a washer or lock-nut on a bolt, imbed expansion-sockets in cement, and a permanent lock-nut, the **Smooth-On Manufacturing Co.** of Jersey City, N. J., advises using Smooth-On iron cement No. 1.

The **Chicago Pneumatic Tool Co.** makes the following announcements:

F. V. Sargeant has been appointed district manager of sales at Boston, in place of F. S. Eggleston. The office at Wichita, Kansas, has been closed, an office and warehouse being established at Eldorado. A new office and warehouse have been opened at Tulsa, Oklahoma.

The **Sullivan Machinery Co.** of Chicago announces the establishment of a foreign trade department. Already this firm has branch offices at Salisbury House, London; Paris; Santiago, Chile; and Sydney, New South Wales; also there are engineering agencies of standing to handle Sullivan products at Christiania, Norway; Amsterdam, Holland; Gijon, Spain; Turin, Italy; Algiers, Tunis; Johannesburg, Transvaal; Durban, Natal; Shanghai, China; Tokyo, Japan; Lima, Peru; and Buenos Aires, Argentina.

EDITORIAL

POTASH from Lorraine is now for sale at New York; it comes from the mines formerly controlled by the Germans. This is an interesting development of our post-war trade relations with France, and although it is unfavorable to our domestic potash industry, we prefer it to the commercial invasion of the German Kali Syndicate.

BRAZIL, as a mining region, is likely to gain by the coming change of government, for the probable president, Sr. Ruy Barboza, is an enlightened and progressive man, with a proper desire to stimulate the development of the mineral resources of the country. He will enter into the duties of his office next June. We may add that the people of Brazil are eager to establish closer relations with the United States.

INFORMATION concerning the prospects of marketing copper in Europe is dribbling into print. It appears that England, France, and Italy together hold about 500,000,000 pounds of copper awaiting consumption. In France and in Italy the importation of copper is under governmental embargo, in order to permit the liquidation of existing supplies. In England manufacturers would be glad to buy American copper but they are deterred from doing so by reason of competition with the Government's stock of metal. It is asserted confidently that Germany will take at least 20 million pounds of copper just as soon as facilities for shipping and credit are available. Meanwhile international business waits for the gentlemen at Paris to conclude their labors.

EVIDENCE of improvement in Mexico is given in the annual report of the United States Smelting, Refining & Mining Company, from which it appears that the amount of silver produced by this company increased to 15,337,000 ounces, as compared with 13,000,000 in 1917 and 11,722,000 in 1916. This speaks well both for the company's mines at Pachuca and for the continuity of operations during Carranza's regime. Apropos of that we note Mr. Simon Guggenheim's remark at the recent annual meeting of the American Smelting & Refining Company; he said: "The Carranza government is daily growing in strength. We have received assurances that in three or four months the Villista bandits will be entirely driven out of northern Mexico." Since this was said the news has come that Emiliano Zapata, who has terrorized the State of Morelos for the past eight years, has been captured and killed, thereby removing a strong factor of unrest. Meanwhile Señor Rafael Nietto has failed in his effort to raise American money for the Mexican treasury, probably because the security was inadequate, and Señor Luis Cabrera succeeds him. This is inauspicious, but it may work for the best.

AMONG the excellent suggestions made at the New York meeting of the Institute—when we say "the Institute," our readers will need no further specification—was one made by Dr. A. R. Ledoux in his admirable little speech on international co-operation in North American mining affairs. He suggested the appointment of a permanent committee on co-operation to work with a similar committee representing the Canadian Mining Institute. Mr. Sidney Jennings gave his prompt endorsement to the suggestion. Perhaps a joint committee, of not more than five, representing the two institutes would serve the purpose. We have neither forts nor cannon on the international boundary, but there exist sundry barbed-wire entanglements that should be removed.

"ALL goes well," says Mr. Lloyd George; and indeed it seems as if good progress had been made by the Conference at Paris. The world waits impatiently for the conclusion of peace, not only to resume normal business but in order to prevent the further development alike of the reactionary and the revolutionary elements of society, both of which are lifting their heads aggressively in the war-scarred regions of Europe, threatening to reduce civilization to chaos. We note with satisfaction that France is to receive the Saar coalfield in compensation for the sabotage and other non-military destruction of the coal mines in the Valenciennes district, notably near Lens and Lille. This destruction was perpetrated with the deliberate purpose of crippling France industrially, and it is only just that reparation should be exacted in kind.

THE canards of the past week have included the assassination of the head of the Hungarian bolshevist government, the purchase of territory by the Japanese, the aeroplane accident to the king of the Belgians, the driving of the Murmansk expeditionary force into the sea, the vexation of the President to the point of calling for the 'George Washington' to ferry him homeward, and the mutiny of American troops on the Dvina. The last item of news may not have been without foundation, for evidently some of the men did demur to further fighting with the Russians, but it was made as sensational as possible, just as if a mutiny among soldiers was not lamentable, if not dishonorable. Every day we are told of things having happened that either did not happen at all or happened in a different way. The correction rarely overtakes the lie. As Dr. Raymond once said, what is printed in the newspapers is not the record of things that actually have been: it is the record of things that might as well have been as not.

GEOGRAPHY is a subject of which we have gained a better knowledge by reason of the War, particularly political geography. The various projects for aeroplane communication and for tunneling are serving the same purpose. When we read of the proposed transmarine flights between Europe and America we learn with surprise the shortness of the intervals of water separating various points of land. For instance, the crossing from Dakar in western Africa to Pernambuco in Brazil is only 1850 miles, and it can be divided by landing on the St. Paul islands, close to the line of the equator. Newfoundland is only 1860 miles from Ireland. Next we learn that the proposed completion of the Channel tunnel, 32 miles long, between England and France, is exciting talk of similar projects, such as the tunneling of the Bosphorus, the Strait of Gibraltar, and Bering Strait, the last about 50 miles wide. An enthusiastic scribbler writes an article headed 'London to New York by Train,' anticipating the accomplishment of these engineering feats, which, after all, are dependent more on policies and money than on physical difficulties. The scribbler just mentioned suggests that the tunnel will "open up the great coal deposits af Alaska," not knowing, apparently, that the Bering River coalfield is in south-eastern Alaska and about 850 miles from the strait of that name. He also speaks of a railway already existing on the Alaskan side of Bering Strait. Well, there is the Wild Goose narrow-gauge track from Nome to Lane's Landing, but that will not help the transcontinental traveler. The next nearest railway is the Government railroad now in course of construction between Seward and Fairbanks, which is 600 miles, as the crow—or the ptarmigan—flies, from Bering Strait. Even then the aid of a ship would be needed to reach any rail system pointing toward New York. On the Asiatic side there is a gap of 2400 miles of wilderness between the nearest rail-head, at Chita, on the Trans-Siberian line, and the eastern entry of the proposed tunnel; indeed, 5000-odd miles of railway through difficult country will be required both in north-eastern Asia and north-western Africa before the traveler can expect to go all the way from London to New York by rail.

MORE than two years ago, in reviewing the famous gold mines of various countries, we selected the New Modderfontein, in the Witwatersrand district of South Africa, as the premier gold mine of the world. This judgment appears to be confirmed by later evidence. Up to date it has paid £4,423,750, equal, at $4.85, to $21,455,177, in dividends, besides about $5,000,000 of capital expenditure. The proved reserve of ore consists of 9,000,000 tons of 8.6 dwt. ore averaging 65 inches in width, and there is probably 15,000,000 tons more to be developed in the ground not yet touched. Assuming a profit of $5 per ton on the whole 24 million tons, and a net divisible profit of 80%, the aggregate distribution, as foreshadowed by Sir Evelyn Wallers, the president of the Transvaal Chamber of Mines, will be $95,000,000 more, or about $125,000,000 altogether. Up to June last the New Modderfontein had yielded $62,500,000 in gold; the average recovery had been 36s.9d., or $9.19, per ton; it is estimated that the future yield will be 36s., or $9, per ton; therefore the gross production of gold, before the life of the mine is exhausted, should be fully $275,000,000. These are imposing figures. The Homestake has produced $159,677,849 in gold and paid $42,000,000 in dividends during 42 years. The ore now averages $4 per ton. We note that the Government Gold Mining Areas, a mine from which the Transvaal government draws a royalty ranging, on a sliding scale, between 10% and 50% of the net produce, is rated as coming next in productivity to the New Modderfontein. The Government property is contiguous to the Modderfontein; it has 8,000,000 tons of ore developed and is expected to yield at least $350,000,000 worth of gold from ore averaging 33s., or $8.25, per ton at a cost of 18s., or $4.50, per ton, yielding a profit of $190,000,000, of which the Government would receive $102,500,000 and the company $87,500,000. Keen rivalry between these two neighbors is anticipated; the Modderfontein will be crushing 100,000 tons per month as against a capacity of 135,000 tons in the Government Areas mill. It is possible that before long the latter will be expanded to a capacity of 2,000,000 tons per annum. This makes our Alaskan dreams look foolish.

Engineering Education

A revival of interest in education appears to be one of the consequences of the War, because that calamitous experience has given us a new datum-line from which to measure the value and effectiveness of mental training. A report upon engineering education has been issued recently by Mr. Charles R. Mann, of the University of Chicago, who has interpreted the mass of information collected by a joint committee on the subject representing the leading engineering societies. Professor Mann finds that the average student fails to gain a fundamental knowledge of science because he is swamped by special studies intended to apply directly to the industries. The sacrifice of the humanistic studies to those of technical interest has caused engineers to neglect literature, economics, and social philosophy; they cannot express themselves in good English nor can they handle men. A circular sent to 30,000 members of the four leading engineering societies elicited the opinion that character is the chief factor in engineering success, while technique was placed at the bottom of the list of qualities. The general agreement on these ratings is most interesting. Evidently the whole question of education is undergoing revision. We must make up our minds whether we intend to train a young man for leadership or for service; is he to be prepared to be a captain of industry or merely to be enabled to earn his bread and butter immediately upon graduation? We need different colleges for different purposes. We give engineering education to men wholly unfitted, morally and physically, to perform the work of an engineer, who is a leader of men, a man that can do what nobody else can do. So we venture to give our own conclusions on the matter. Let us start with a definition: education means 'drawing out': it signifies the development of the mental faculties, primarily for usefulness in life. Any process of training that exercises, invigorates, and disciplines the intellect is an 'education'; the process that supplies the brain with the memory of things and furnishes rules for doing them is 'instruction'. The best discipline for logical thinking is the study of mathematics. To "reason closely and in train" is the first step in science. A thorough schooling in mathematics, therefore, is essential. Then should follow physics, in which mathematical reasoning is given material form. Physics involves a knowledge of chemistry, as mathematics includes arithmetic. From inference and observation, we conclude that the most capable engineers have had a good training in mathematics, chemistry, and physics. Many clever men have failed in the crisis of their professional work because they lacked such a training. The success of the Columbia men, as we knew them in Colorado thirty years ago, is to be credited mainly to the severe grueling they received in mathematics. "Do ye ken Van Am?" The college song has a deeper meaning than most of its kind. To learn anything thoroughly is educative. To study Greek is a better preparation for mining engineering than to obtain a smattering of mechanics and geology. What is learned is less important than how it is learned. The thorough learning of a subject is discipline, the effects of which will endure. The smattering of a subject is a cerebral dissipation, enervating to the mind. A course of mining engineering should deal mainly with principles, not details of practice. Methods change; principles remain. The memorizing of facts is less important than the ability to understand their relation to one another. This is scientific: that is childish. The 'Principles of Copper Smelting' will help the student long after the same author's 'Practice of Copper Smelting' has become obsolete. The detailed description of ore-dressing soon becomes a matter of history, but the rationale of the process is never old. What is needed is a thorough grounding in the elements of science and the ability to reason logically on the operations of Nature; to learn how to learn; to know where to find knowledge. We venture to make another suggestion: that young engineers should be taught to use with precision their most important tool—the English language. Many members of the profession are handicapped throughout life by their inability to write well. Clear thinking and clear writing are two phases of the same mental process. They react mutually. It is a pity that among many of our young engineers in the West it is deemed effeminate to be refined in speech or graceful in writing. Such a notion is a sure sign of a defective education, for one of the best products of human culture is the ability to communicate thought and exchange ideas. It is well, therefore, to master the instrument of expression. Nor shall we close without reverting to the factor of character. Herbert Spencer long ago said that "of all the ends to be kept in view . . . all are unimportant compared to the end of character-making. This alone is national education." In the last resort mere cleverness will not take a man far; there is needed something more dependable, and dependability is character. A man of character will act the same way under the same conditions; he can be depended upon to do what is right, for 'character' stands for good character, a mental and moral endowment helping the individual man to become an exponent of ethical ideals. Whether that can be taught at college, by maxim or by association, is another problem. Is it inherited or is it the product of the right environment? We incline to the hopeful view that much can be done by precept from honored teachers and by contact with high-minded companions. The old world has its *noblesse oblige*, have we not a democratic ideal of conduct that will coerce to right ways?

Bolshevism Upstairs

Two topics are occupying the mind of the community: prohibition and bolshevism. Alike they have been assisted to a remarkable degree by a campaign of propaganda, itself a consequence of the facilities afforded to the products of the printing-press by a highly organized system of distribution, not only by means of rail and motor transport, but even, as happened in Europe when it was desired to reach enemy countries, by aid of the aeroplane. Prohibition and bolshevism are unlike in so far as the one aims to restrict and to discipline the habits of the citizen, whereas the other appears to remove all restraint and gives free rein to the bestial instincts of mankind. When, however, the eagerness to discipline members of the community goes so far as to disregard an implied contract between those in authority and citizens engaged in legalized industry, it would appear as if the intoxication of anarchy had taken possession of the protagonists of prohibition also. We venture to quote an interesting example, namely, the treatment of the grape-grower in California. The facts are as follows: The cultivation of the grape came to California with the Padres; wine was made first at the Missions and later by several Spanish land-owners. The Mission of San Gabriel was known in 1829 for the good wine it produced. In 1832 Don Louis Vigne, a Frenchman, living near Los Angeles, imported cuttings of choice varieties of the grape from the Bordeaux district; he was also the first to engage in the growing of oranges on a commercial basis. The American immigrants drawn hither by the lure of gold were at first too excited for patient industry, but the wave of migration brought many Europeans to California, and among them were several versed in the making of wine. Some of these, having had their fill of mining, turned to viticulture. They succeeded so well that in 1855 the Legislature was asked to aid the industry, but nothing was done at that time except to award prizes at State Fairs for the best exhibits of the wine and brandy made by these pioneer vignerons. In 1861, however, the Legislature authorized a commission "to promote the improvement and culture of the grape-vine in California" and the Governor appointed Arpad Haraszthy, a Californian wine-grower, to make "an examination of the different varieties of grapes and the various modes of making wine in the vine-growing countries of Europe." This commissioner made a report of 420 pages, published by Harper & Brothers in 1862; he also purchased 100,000 grape-vines, representing 400 varieties, for importation from Europe to California, where they were planted successfully. During the two following decades not much was done by the State in this matter, but in 1880 an act was passed to promote "the viticultural interests of the State" and to provide a Board of Commissioners for the purpose. According to the Act it became the duty of the Board of Regents of the State University to give special instruction in the arts and sciences pertaining to viticulture. For this work the Legislature voted biennial appropriations, increasing until the Commission was receiving $17,500 per annum and the University $5000. This provision continued until 1894, when the Viticultural Commission was abolished and its effects transferred to the University, which proceeded with the study of viticulture with its own funds until, in 1913, the State organized a second Viticultural Commission, which it maintained until the present time at a cost of $7500 per annum. Thus the patronage and promotion of the State covered a period of about 40 years, with but slight interruption. The amount of money spent by the State was at least $300,000 and the stimulating literature resulting therefrom is voluminous. Nine-tenths of the work dealt with the wine-making phase of grape-growing; it was for the wine industry, not the production of raisins and table-grapes, that the State expended its money; for the establishment of this industry it made persistent effort. Thus blessed by Church and State the wine industry has grown until it uses 170,000 acres, apart from the 110,000 acres devoted to raisin-grapes and the 50,000 acres given to table-grapes. On a conservative valuation these vineyards are worth $200 per acre. The total investment in the 330,000 acres of vine-lands, together with plant and equipment, is estimated at $150,000,000. The value of the annual crop in 1918 was $46,220,250, as compared with $68,000,000 in 1917. The wine-grapes last year were worth $10,039,250, of which $5,950,000 represents the dry-wine grapes that are unsuitable for table use, for raisins, or for other purposes. The chief loss falls upon those whose grapes cannot be used for secondary purposes and whose vineyards have a soil unfitting them for any other cultivation except hay; for example, those of the foot-hill region in the counties of Napa, Sonoma, Mendocino, Contra Costa, Santa Clara, and Santa Cruz, who face a shrinkage in value from $175 or $200 to $25 or $30 per acre. The industry occupies 15,000 heads of families, that is, about 75,000 people are directly engaged in viticulture. It has claimed the education, energy, and devotion of many worthy citizens, who now face not only the extinction of their livelihood but the implied opprobrium of the community, due to confusing the saloon-keeper, who sells very little wine, with the wine-producer. The supposed affiliation of the liquor-dealers and the saloon-keepers with the grape-growers and wine-makers is due mainly to the fact that they were placed in the same class for purposes of internal revenue. That, however, is another story. We must treat this matter as an accomplished fact. The State encouraged its citizens to embark in the wine industry and the Federal Department of Agriculture also aided and abetted it to no inconsiderable degree. If an individual or a group had issued a glowing prospectus to induce the purchase and use of land with knowledge of impending confiscation of the industry to which the land was to be put, they would be placed under a criminal charge of using the mails to defraud; if they did it innocently, they would still be financially responsible to a purchaser who had depended upon their representations. Does the State escape a similar responsibility? Must these people, who have put their knowledge, energy, and capital into the wine-making business under the persuasion and guidance of the State, lose the major part of their property owing to a change of public opinion? Is this the square deal? It is no excuse for the State that prohibition against the making of wine is of Federal origin and contrary to the wish of the people of California as expressed by vote. The State is responsible because it promoted the industry more, and it benefited by the values and the trade created more than the Federal government. The position is comparable with the condemnation of private property for public use, which in this case is the change of public sentiment toward alcoholic beverages. The damage is manifest and the amount of it can be proved. It is not large, but whether large or small, it should be recognized as a matter of principle. We have condemned the German idea of the State because it claimed immunity from the morality it imposed upon its citizens; we condemn the Bolshevists because they disregard the rights of others and ride roughshod over the obligations created by the social code by virtue of which law and order are maintained in the community; shall we approve this apparent breach of good faith on the part of our own State? In all such matters not only should a good example be set by those in authority, but we go further and insist that unless municipalities, States, and the Federal government alike exhibit a consistent regard for their obligations to the citizen, individually and collectively, they undermine respect and sow the seed of anarchy.

Mining: An Investment, a Speculation, or a Gamble?

By T. A. RICKARD

*The Chairman of your Program Committee told me that the subject allotted to me was 'Mining as an Investment'. I assume that he meant the gainful use of money in mining, that is, the making of money through the exploitation of mineral deposits, not other people's pockets. However, I deem it well to start by defining the terms to be used in the present discussion, because definitions are essential to a correct understanding of any subject.

Money can be employed profitably in three ways: investment, speculation, gambling. An 'investment' looks to income; the use of the word assumes the comparative safety and stability of the principal. A 'speculation' looks to an increase of the principal; the use of this word suggests the minor importance of interest, income, or return on capital; it assumes not the stability, but the comparatively rapid appreciation of the principal. A 'gamble' involves a risk so large as to require the aid of luck; it ignores interest or income; it anticipates the alternative of a big winning or a total loss.

Obviously the definition is subjective; it is based upon the expectation of the individual making the purchase. To one man the use of money for a certain purpose is an investment; to another man the same use appears to be a speculation. Similarly, one man's speculation is another man's gamble. Six years ago Mr. Lloyd George and Lord Reading, then Sir Rufus Isaacs, were persuaded by Mr. Godfrey Isaacs, a brother of the present Ambassador and Lord Chief Justice, to buy a block of American Marconi shares as an 'investment', that is, as a steady dividend-payer. Three days after Mr. Lloyd George had bought his shares they rose so rapidly that he sold them, on the urgent advice of his broker, to whom he was disinclined to listen because his intention was to hold the stock "as an investment." He was then Chancellor of the Exchequer, therefore he was hauled over the coals for 'speculating'; he was charged with a levity of conduct unbecoming the chief of the British treasury. He replied by saying that when he bought the shares it was his intention to hold them indefinitely and that the sudden and surprising rise justified him in selling. In short, his 'investment' had proved a 'speculation'. The distinction is in the mind of the purchaser. Similarly a Boston school-teacher may buy the shares of the Great Wildcat Extended as an 'investment', whereas a Wall Street broker recognizes that it is highly 'speculative', and a Nevadan mining engineer knows that it is a rank 'gamble'. These terms are relative; they connote a crescendo of risk; even an investment has a slight element of risk; a speculation has more, a gamble, most. Sometimes a stock is bought on the expectation of a rise; it remains steady for years; it proves to be what is called a 'forced' investment. The idea of expectation is implicit; the human factor is never absent; we are dealing not with lexicons but with human affairs.

The other significant word is 'mines'. A mine is an excavation in the earth's surface from which mineral is extracted. It is not a company nor the shares of a company owning that excavation. A flippant definition says that a mine is a hole in the ground with a liar sitting on top. A promoter is said to be a man who sells something he has not got to somebody who does not want it, or, if you prefer, a promoter tries to sell nothing for something to a man who expects something for nothing. However, these perversions of honest business do not concern us for the moment; my subject is the reasonable speculation that is based upon the legitimate exploitation of mines. Permit me to remind you that the word 'mine' was used in the arena of warfare before it entered the field of peaceful industry. It comes to us through the Latin *mina*, signifying an excavation to be used for killing the enemy. The original sense of the word survives in 'minatory', meaning threatening. During the War we have heard more of mines in the North Sea than of mines in Mexico, for example, and you will allow that those who sailed the seven seas had to deal much with speculation concerning mines, and the flotation of mines on water, reminding us of minatory performances on the stock exchanges during times of peace. Now, however, we hope soon to forget the derivation of the word and to interpret it, not in terms of maleficent activity, but of beneficent industry.

You will note that I have chosen 'speculation' in preference either to 'investment' or 'gambling' as the more appropriate to mining. The use of money in mining is seldom an 'investment'; usually when it is meant to be so it affords an example of the triumph of hope over experience. I admit that certain forms of iron and coal mining on a large scale are characterized by such security, continuity, and steadiness of income as to be 'investments', but the mining of the so-called base metals or of the precious metals, in which most of you are engaged, does not come within the category. In metal mining the chance of a considerable risk and of a correspondingly large gain is inherent. Some of you will demur, you will point at the Homestake, the Bunker Hill & Sullivan, or the Utah Copper as examples of an investment, as representing a type of security so safe as to be gilt-edged, but I venture to say that your opinion is *ex post facto*, you are writing last year's almanac, you are wise after the event. The history of such persistently profitable mines causes you to regard them as safe because you can retrace their history for ten, twenty, or thirty years. You imagine yourself buying into such mines soon after they had undergone preliminary development and you know that if you had done so at an early date your purchase would have proved extremely remunerative; but I submit that in the early stages of development these splendid enterprises were speculative, as is suggested by the fact that these successful ones are a few of the survivors from the much larger number that were started at about the same time and proved disappointing. I may remind you, to make my point quite clear, that many of the famous mines of the world 'broke' those who first attempted to bring them to financial success. If today you were to advise a widow to put her savings in any one of the three magnificent mines that I have instanced, you would, in my opinion, be an unwise counselor, because looking forward, not backward, for ten or twenty years, they would represent a speculative use of the widow's savings. You might be sagacious in using your own money for such a purchase, because you could take the relatively small risk for the sake of the probably large gain, but the widow would be better advised to buy Liberty bonds.

---

*An address delivered before the International Mining Convention at Vancouver, B. C., on March 17, 1919.

At this stage of my argument I beg you not to be annoyed at my apparently over-cautious attitude; you will find that my conclusions will not depreciate the industry in which you and I alike are so deeply interested. I shall hammer my point home by one further suggestion. You would not be willing to lock up your mining stock in a safe for five or ten years, as you might do with first-class bonds; you know that in the course of five years the fluctuations in market-value are likely to be so wide as to compel you in your judgment either to cut a loss or take advantage of a market-profit. On the other hand, a mine is not a 'gamble', because the risk it involves is not unreasonable; it is diminished by knowledge and experience, it is lessened by the skill you can apply both to the finding and to the treatment of the ore. A miner always needs some luck, of course, but his luck is a friendly sprite, not the grinning devil that sits by the roulette-wheel. Every business involves one or more indeterminate factors and therefore contains an element of risk. Without risk there is no gain; but a large gain usually involves a large risk. There are people in mining, of course, that take big odds, that like a reckless bet; they are real gamblers, even if they are unaware of it; but the risks taken in legitimate mining are under some measure of control, they are met by scientific knowledge and by trained intelligence. A blend of pluck and judgment is required. You will recall a line in Kipling's poem, 'The Merry Gloster': "And I took the chances they wouldn't and now they're calling it luck." That is why I insist that mining, properly conducted, is not a gamble. On the other hand, no man of experience in these matters would expect to escape all the risk. The idea of eliminating risk from mining is both contrary to the spirit of the business and false to the history of it. To understand mining—to appreciate the principles guiding legitimate and successful speculation in mines—which is my subject—you must revert to the old Cornish word for shareholders; they were called 'adventurers', that is, men willing to make a venture.

Indeed the idea of avoiding risk in mining is a pathetic fallacy; a puerile endeavor to escape the inevitable. The attempt to find mines that would involve no risk to the capital sunk in them has tended to cripple the industry; the refusal of sundry so-called exploration companies to incur risk has stultified their operations and paralyzed development. And I may add that this policy has warped the judgment of some otherwise brilliant engineers. The story is told that Marcus Daly sent a mining engineer on a scouting expedition; he examined many prospects, without finding anything worth while. Daly became impatient; he slapped the engineer on the shoulder and exclaimed: "For God's sake, man, go out and spend some money." There is too much of a desire to play safe by buying mines with large blocks of proved ore, and to make money by means of an enlarged scale of operations, increased skill, or improved methods of metallurgy. The finding of ore, which is the real adventure, is relegated to the background; it is not only the chief attraction of mining, but the one that wins the greatest reward. When the ore-reserves of a mine are at a low ebb it may be the most speculatively attractive time to buy the property. There are those who say that the mining of the future will be the economic harvesting of known ore deposits of low grade, the beneficiation of masses of mineral already discovered, but heretofore regarded as too refractory for successful metallurgic treatment, that is, the utilization of the visible supply of skimmed milk instead of the finding of the metallic cream concentrated by the patient operations of Nature. I doubt that; the world is still young, and but half-explored, as is suggested by such discoveries as those of Nome, Cobalt, Porcupine, Tonopah, Goldfield, the United Verde Extension, the Bawdwin mines in Burma, and a host of other bonanzas during the last twenty years.

One does not need to be venerable in order to recall great changes in the philosophy of mining economics. In 1905 I published a book on this subject, in which was included a discussion upon various aspects of mining finance. Among those contributing, besides myself, were H. C. Hoover, J. H. Curle, and W. R. Ingalls. Mr. Curle, at that time the leading London authority on such matters, a man of wide travel and stalwart independence of mind, advised his countrymen to stick to gold mining as being the safest, because gold had a "fixed value." We know today, by unpleasant experience, how gold can so depreciate in terms of other commodities that the gold miner is placed at a decided disadvantage. Mr. Curle insisted that the only correct kind of gold mining was based upon a careful estimate of the ore in reserve, and that at least 60% of the price of the mine ought to be represented by net profit from the developed ore. He even went so far as to lay down the rule that gold mines should yield 10% of their market valuation. Later he put the interest at 15% We have traveled far since then. Most of these *obiter dicta* served a purpose in their day, fifteen years ago, as a means of educating the British shareholder, who is a simple-minded person, because Mr. Curle accompanied them with much straight information and trenchant criticism, but all such attempts to compress mining into a formula are a failure. They were based largely on the experience—then incomplete—of the Rand, in South Africa, where continuous beds of gold bearing conglomerate were being exploited on the largest scale known to the modern world. These beds of 'banket', as they were called, after the Boer name for almond-cake, were comparatively uniform in their gold contents and were mined and milled so cheaply as to yield handsome profits. Their uniformity of grade and persistence in depth caused them to be regarded as the basis for 'investments' of the safest kind, suitable for widows and orphans. Later experience has shown that they were neither so uniformly nor so persistently rich as had been expected, the result being to turn the 'investments' into 'speculations', out of which a comparatively few made a great deal of money and comparatively many lost more than they could afford. The Rand proved to be the greatest goldfield in the world, in extent and in yield, but I am making the point that it did not escape the vicissitudes latent in mining, and the successful effort to persuade the public that it would escape those vicissitudes led, in the end, to a tremendous and widespread loss of money, which passed from the pockets of the public to those of the promoters. Money was made honestly on the Rand during the development stage, when adventurous spirits risked a total loss of their stake in order to make a big gain; but when the operators and promoters turned to the man of small means and persuaded him that the latent risks were eliminated and that a gilt-edge investment was available to him in the stock of over-capitalized mines, they deceived him. Some of the operators and promoters knew no better; others were advised by good engineers, and simply victimized the unsuspecting by unloading their holdings upon them at a handsome premium. To illustrate how the public was victimized, I can state that the market-value of the shares in the three principal companies representing consolidations of groups of mines declined $203,931,610 between 1911 and 1918. That huge loss was due to ignoring the common experience that mines eventually become impoverished in depth, just as surely as men grow old, and also to the assumption that a 60% ore-reserve, that is, having 60% of the market-value 'in sight', furnished ample security. In the attempt to introduce one or two academic factors of safety the public was led to ignore the very essentials of the business, namely, that it involved no small risk, under the best conditions, and that the risk must be compensated by large dividends. Instead, the public accepted 6 or 7% as an adequate return and failed to recognize that they held a wasting asset. During the speculative—the frankly adventurous—stage of Rand mining it made money for nearly everybody engaged in it, but when the chicanery of the few was combined with the ignorance of the many into creating a false notion that the speculative phase had been transformed into one of secure investment, then it was that share dealing on the Rand became a cause of great loss to the public and a blot on honest industry. From the moment when the change in sentiment was effected, and the fallacy was established, the mining of the gold became less profitable than the mining of the pockets of the public.

This investment idea, of minimizing risks and limiting possibilities, would soon cause mining to die for want of breath. Before a profitable outcome is assured every mining enterprise must pass through several stages of speculativeness as surely as a child must take the chance of bumps and bruises, of measles and mumps. The biggest fortunes are made during the early stages of development; on the whole, more money is made by selling than by buying mines, simply because the final or so-called investment stage of a first-class mine is likely to represent an over-valuation, caused by an erroneous supposition that the essential hazard is precluded. I would even say that more money has been lost by the over-valuation of the great rich mines of the world, like the Con. Virginia, Mount Morgan, Broken Hill, and Nipissing, than in a multitude of worthless prospects. Small men lose their money in big mines, and big men in small mines. The inference therefore is not to try to get rid of the essential risk—because it cannot be done—but to require a rate of profit proportionate to it. A much more intelligent policy is to engage in such mining as allows a liberal margin both ways, taking a larger risk for the sake of the larger gain, that is, to speculate with eyes wide open, and not to invest with eyes half-shut.

Fifteen years ago the careful sampling of ore as a means of valuing mines was becoming advanced to an art and the tendency was to place great reliance upon it, with the consequence that capitalists began to think themselves safe in buying ore. They thought to escape the essential risk by assuring themselves a return of their money, diminishing the speculative features of the business as much as possible. Exploration companies were organized in London, New York, and Boston to scout for promising mines on which to apply the newly developed methods of valuation. Most of these seekers after bonanzas were disappointed; they failed to repeat the successes of the pioneers in this type of mining finance—such as the Exploration Company of the Hamilton & Smith era—because they were too timid; they expected to have their money in sight when they bought a mine; they were looking for a bet on a sure thing, with all the profits of a speculation. They lacked the temperament needed for adventure and should have placed their money in a bank, where at 4% it would double itself in 15 years. Many directors of these exploration companies bluffed themselves into the idea that they were bold navigators, when as a matter of fact they were only fair-weather sailors.

As I remarked at that time, "ore-reserves are not everything; expansion and development are the essence of successful mining." The big successes have been made by developing prospects into mines, not by buying blocks of ore that have been exhaustively sampled by meticulous young men. The profit to be made must depend upon the further extension of the ore; the larger the proportion of ore already proved the smaller the possibilities beyond. As Mr. Hoover pointed out, the probable depth of extension is more critical than the proportion of profit in sight. He worked out a rough rule for the gold mines of Western Australia, namely, the minimum extension of an orebody in depth should be not less than one-half its length. He called it a 'yard-stick' for use in forming a judgment, but he laid stress on the need for investigating the characteristics of the individual orebody, more particularly its geologic structure and that of the district in which it lies. Such a rough and ready formula, however, would fit only the mines that are dependent on one or two large shoots; it would be of little service in the valuation of mines depending on a series of recurring ore-shoots, as, for example, the Goldfield Consolidated, in Nevada, the Nipissing, at Cobalt, the Yoquivo, in Mexico. Mr. Hoover made the shrewd observation that "the quantity of ore in reserve is a matter of management not necessarily dependent on the size of the mine." In 1912 Morton Webber protested against the use of formulas in mine valuation and showed that "the relative magnitude of the ore-reserve in any particular mine is largely a matter of administrative policy." I myself remember, when practising as a mining engineer, advising a client not to extract the ore in his mine if he hoped to sell it to advantage, as he wished to do. The extension of the orebody was menaced by a fault. He listened to a saw-mill engineer, enlarged his mill from 20 to 40 stamps, extracted all the ore, and barely made enough profit to pay for the enlargement of the plant, leaving a hole in the ground in which several later operators have buried their good money. This was a gold mine in Idaho. Another example occurs to me: a small silver mine in Colorado. The ore was only five inches wide, but high-grade. A careful sampling showed $150,000 worth of ore assured, which would yield a net profit of $110,000. The owners were willing to sell for that sum, half cash and half in six months. I advised my clients not to buy, because the winzes below the adit-level showed that the vein was poor and much faulted. The history of neighboring mines was not promising as to prospects in depth. I considered the business unattractive because the risk of the known ore yielding less than the amount of profit estimated seemed to outweigh the chances of finding more ore. The subsequent story of the mine justified my opinion. On the other hand, I advised the purchase of the Camp Bird, in Colorado, for $6,000,000 when the bottom workings looked poor, and gave no promise of the ore persisting, because I believed that horizontal exploration would lead to the uncovering of more orebodies, especially westward, where the rising surface gave virgin ground increasing to a height of 1200 ft. above the adit. The mine had reserves equal to $6,118,000 gross, but the value of it lay largely in the good prospect of the further finding of rich ore, without sinking, as the sequel proved, for the Camp Bird has produced $20,000,000 since then, although poor in depth. Please pardon these reminiscences of a time, 20 years ago, when I was a mining engineer, not a journalist. I give them because personal experience is direct evidence.

In 1911 M. H. Burnham contributed a series of articles on sundry principles underlying the finance of mining enterprise, more especially the 'risk-rate'. He insisted rightly that the buyer of mines or shares in mines should expect not only a bank-rate of interest on his capital, but as much more as will cover the additional risk inherent in the business of mining. If, as I suggested at that time, he bought into the Goldfield Consolidated, in Nevada, then the most productive gold mine in the world, but with a reserve of ore so small as compared with its annual production as to ensure the return of only a small part of its market-value, he, the sane speculator, ought to expect a dividend of 35% per annum, or 31% more than the 4% bank-rate, that is, the mine should be valued on the basis of a three years purchase. This famous mine is now in the hands of lessees; its story has been told, and you can ascertain how nearly right was my diagnosis of the position. However, it is only mentioned as an example. On the other hand, a mine like the New Modderfontein in South Africa or the Homestake in South Dakota might show a life and a standard of production justifying a low estimate of risk, thus warranting a much smaller return, say, 6% more than the bank-rate. It amounts to this, that after an engineer has examined a mine and measured its ore-reserves, he must determine the risk-rate at which his clients' capital may be used in the purchase of that particular property. This risk-rate will be based upon the past history, the present condition, and the future prospects of the mine.

The sampling of mines has been allowed to obscure the need for good judgment. It is also another phase of the attempt to make an investment out of a speculation. The ore in reserve in a mine should be regarded chiefly as an indicator of the probability of being able to find and develop more ore of the same grade. The expectation of a profitable venture should be based not upon the extraction of the known ore, but upon the chances of further intelligent search.

A so-called 5% investment in a metal mine is an unwise use of money because the interest is too small for the risk, whereas a 20 to 25% speculation in a metal mine is sagacious, if the probable risk is compensated by the probable gain. As Mr. Hoover says, "there is an inherent speculation in mining, and it is this speculation that attracts." It attracts those that understand. It is the spirit of adventure that stimulates the best kind of mining. For instance, the controllers of the Homestake mine have spent 15 million dollars in 15 years on the Cerro de Pasco; they have received their money back and 100% added thereto, equal to about 7% in the 15 years, and now they have proved ore sufficient to last for 20 years. That is what I call a fine adventure!

The speculative side of mining has an attractiveness that is at the bottom of the energy with which it is fol lowed, and when you bring it to the dead level of a steady investment you will find that the man of ordinary shrewdness saves time by going straight to his broker and buying bonds or consols. This does not mean that one is justified in playing the fool and expecting miracles to happen. The risk of mining should not be increased needlessly by human aberrancy. Mining enterprises come to grief often not so much on account of the failure to attain an investment basis, but because they are not put on a business basis. Even if the occurrence of ore in nature be erratic, and mining as a consequence be hazardous, there is no justification for piling human foolishness on top of nature's vagaries.

A large part of the public participation in mining is done by means of share-buying; this is a secondary and a less desirable form of speculation, as compared with the ownership or part-ownership of mines by individuals, partnerships, or small syndicates. It is a legitimate means, however, of distributing risk and of applying collective capital to undertakings too burdensome for an individual or a syndicate. It produces a fluctuating ownership. In practice, whatever may be his theory, the American 'investor' does not buy mining stocks to keep. Whatever he calls such holdings, he treats them as 'speculations'; he does not put them away for the sake of their dividend yield; he is always ready to realize upon them at an enhanced price; he buys them to sell. It has been said that the ownership in an American mining company changes, on an average, every five years. Hence the mysteries of amortization do not interest most of our people. They are looking for a quick turn-over, not a long-time investment. The individual owner of a mine rarely keeps it when it grows to a size involving a large amount of capital; he spreads the risk and gathers his winnings by disposing of the mine to a public company. Long-continued private ownership of a profitable mine is rare. W. B. Bourn and his father before him have controlled the Empire mine at Grass Valley, California, for 50 years, and I may add that this mine has been worked uninterruptedly for 66 years! It has proved a real investment, although started, of course, as a speculation. I venture to say, however, that if anybody were to buy it today on Mr. Bourn's valuation, or on that of an equally competent appraiser, he would be compelled to take it as a 'speculation,' for the simple reason that the odds are largely against the Empire mine continuing to be worked profitably in the future for any such length of time as in the past.

Of well-conducted mining ventures it can be said that they meet with a measure of success as large as, if not larger than, an ordinary manufacturing enterprise. I make no apology for mining, it has been—and is still—a glorious adventure for the youth of the world, for those young in spirit as well as in body. To mining we owe the exploration of the far corners of the earth and the development of its waste places. From the days of the Argonauts to that of the beach-diggers of Nome the call of adventure has caused men to go forth into the wilderness and prepare the way for the establishment of industry, for the extension of civilization for the making of homes, which is the best fruit of human toil. If we stifle that spirit of adventure between formulas, if we suppress it by the maxims of an unreasoning caution, we shall shrivel a great industry into a picayune trading which will commit suicide in due course. No; risk is the very essence of mining; it is its life, and the true miner faces the risk with the cheerful confidence of the men who made the world more spacious "in the times of great Elizabeth," of the Argonauts of the Golden Age in California, of the trappers and *coureurs de bois* who opened up the great North-West.

Dredging and Hydraulicking Results of the Yukon Gold Co.

This company in 1918 operated five dredges near Dawson in the Klondike, one at Iditarod in Alaska, one on Prichard creek in Idaho, and one each on the American, Butte, Feather, Trinity, and Yuba rivers in California. The total gold recovered by these boats was $1,884,957, compared with $3,460,668 in 1917, and $3,853,125 in 1916. A table of operating results for last year follows:

	Alaska	California	Idaho	Klondike
Yardage	644,125	4,144,404	*1,148,306	2,767,058
Yield per yard, cents	83.06	7.00	12.97	30.87
Cost per yard, cents	75.72	6.00	7.30	34.30

*Includes December 1917, when this new boat commenced work.

None of the above costs include depreciation.

The Iditarod dredge worked 198 days, 6 days longer than the previous season. Floods caused much trouble at the power station. Hard 'reefs' of bedrock and clayey material reduced the capacity. The percentage of frozen ground thawed and dug was 97.72%, 11.17% more than in 1917. This boat is to be dismantled, as it has worked out its ground.

In California, the American River boat only worked 31% of the possible time, due to low water, shallow ground, and shortage of power. The boat on the Yuba suspended work in December, in order to re-arrange the tailing discharge, to conform to government regulations.

The Klondike dredges worked 139 days, 12 days shorter than in 1917, but they operated 90.1% of the possible time. Of the ground dug, 80.5% was frozen and had to be thawed with steam. No. 2 dredge has completed its area, and is to be moved.

Hydraulicking near Dawson moved 2,054,390 cu. yd., yielding 16 cents per yard at a cost of 8.4 cents. Each miners' inch of water moved 4.34 yards, and 473,115 inches was used in 129 days. The water supply in June, July, and August was excellent, but in September it was unusually limited.

The total gold yield of the company last year was $2,283,862, including that from miscellaneous operations.

Ceylon exported 15,453 tons of graphite in 1918, against 27,047 tons in 1917. America took 55%, a decrease of 26%. Lump plumbago sells for 5 to 10 cents per pound.

HARVESTING THE SALT

The Recovery of Salt From Sea-Water

By F. H. MASON

Probably the most complete series of investigations of the composition of sea-water was that made by Dittmar during the 'Challenger' expedition in 1884, when 77 samples were taken from different parts of the ocean. Dittmar found that, while the total of the solids varied in different samples, their analysis was remarkably constant. They showed an average solid content of 35.976 parts per thousand, and had an average density of 1.0297. The solids gave the following average analysis:

	%		%
Sodium chloride	77.758	Calcium sulphate	3.600
Magnesium chloride	10.878	Potassium sulphate	2.465
Magnesium sulphate	4.737	Calcium carbonate	0.345

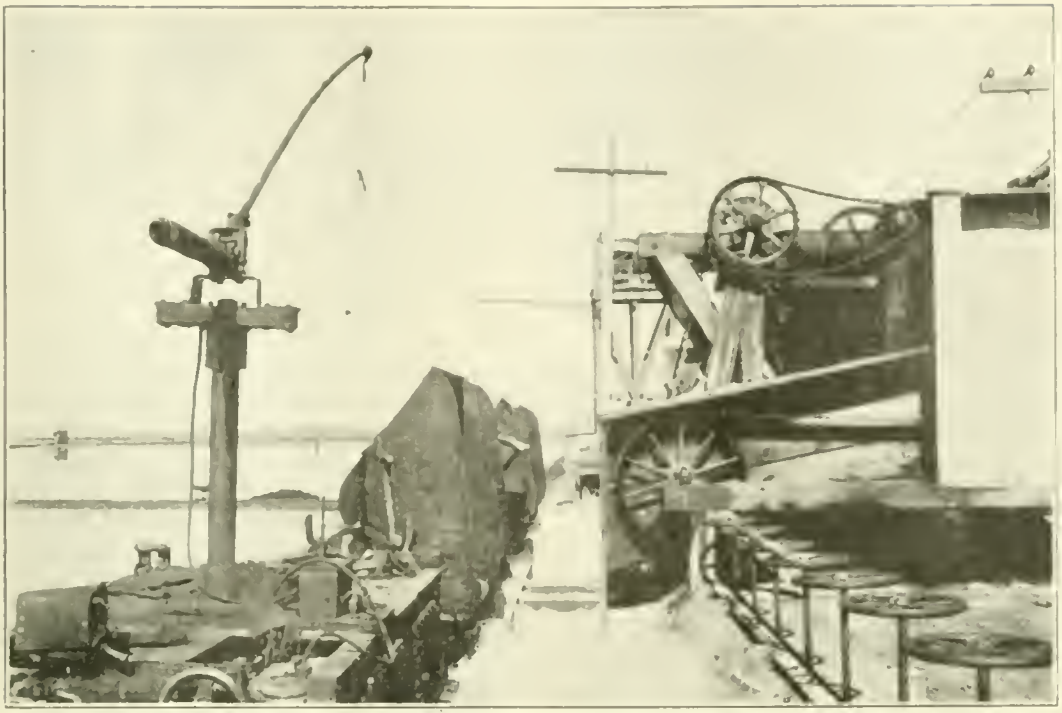
About ten years later, Thorpe and Morton made a more complete analysis of water taken from the Irish Sea. Their analysis follows:

	Parts per thousand		Parts per thousand
Sodium chloride	26.43918	Calcium carbonate	0.04754
Potassium chloride	0.74619	Lithium chloride	trace
Magnesium chloride	3.15083	Ferrous carbonate	0.00503
Magnesium bromide	0.07052	Ammonium chloride	0.00044
Magnesium sulphate	2.06608	Silica	trace
Magnesium nitrate	0.00207		
Magnesium carbonate	trace	Total	33.85946
Calcium sulphate	1.33158		

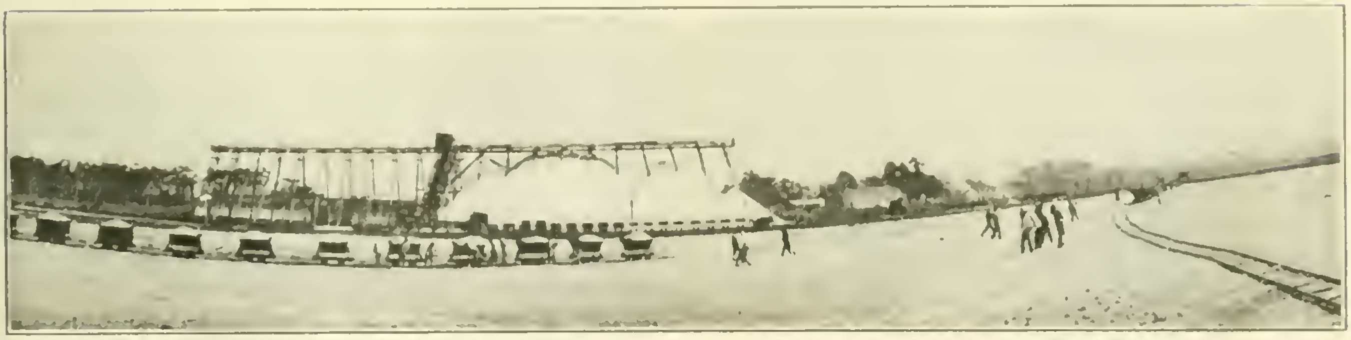
It will be noticed that Thorpe and Morton suggest a slightly different arrangement of the combinations between bases and acids, but this, of course, is a purely theoretical difference.

It will be evident, then, as there is only about 3½% of solids to obtain which 95.5% of water has to be evaporated, that in selecting a site for a salt-works the principal things to be considered are a light rain-fall and rapid evaporation, caused by high temperatures combined with wind and absence of excessive atmospheric humidity. The Western Salt Co. is fortunate in its site at Chula Vista on San Diego bay, eight miles from the city of San Diego. The evaporation at this point, which, of course, like the rain-fall, varies from year to year, averages 60 inches per annum, from which must be deducted the average rain-fall of 10 inches, leaving a net evaporation of 50 inches. The principal unit of the San Diego water-system is so situated that it impounds practically all the water from the mountains in this neighborhood, but little fresh water finding its way into the bay at this point. This, under ordinary circumstances, is a great advantage, as the south end of the bay is shallow and forms a huge evaporating basin, giving the water an appreciably higher salt-content than that of the Pacific Ocean outside, but it proved to be disastrous in January of 1916, when the phenomenal floods broke the Lower Otay dam of the city water-system and caused the practical annihilation of the salt gardens and the 'durostone' or 'woodstone' works connected with them. Since then the salt plant has been rehabilitated, though it has not yet reached its pre-flood capacity of 15,000 to 20,000 tons per year, and a substantial dam is being erected by the city, which guarantees the prevention of a like disaster.

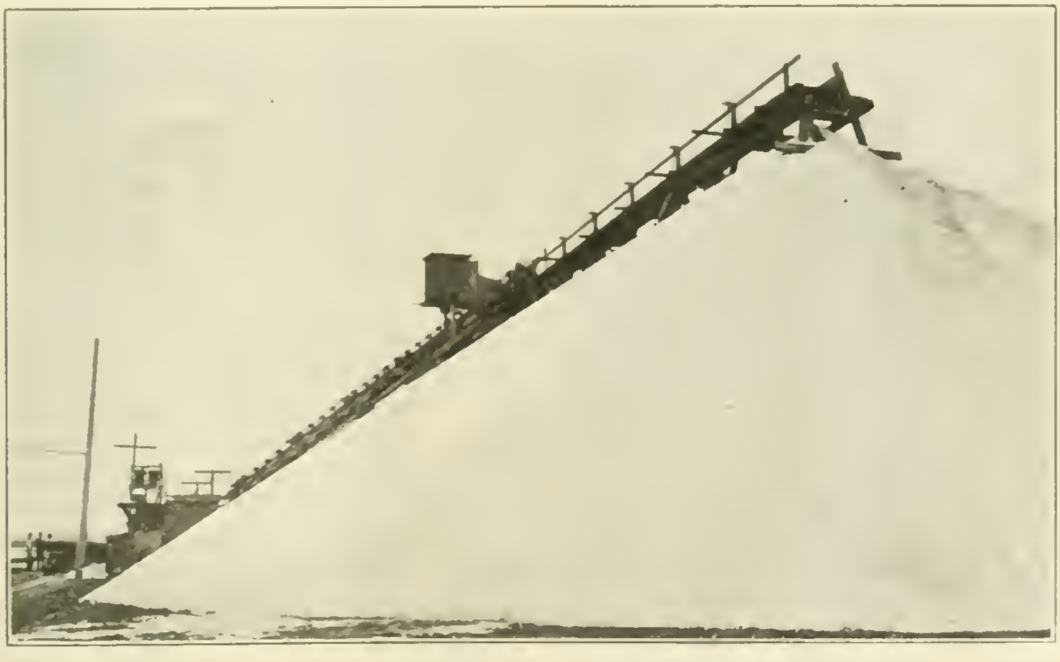
The salt gardens cover an area of 600 acres, and consist of a number of shallow pools known as tide-ponds, secondary ponds, lime or pickle ponds, and crystallizing-vats, divided from each other by embankments on some of



DUMPING-HOPPERS AND CRYSTALLIZING-POOLS



GENERAL VIEW OF THE SALT WORKS



SALT DUMP, SHOWING TRESTLE AND BASKET-BELT which are car-lines to facilitate the harvesting of the salt. Water from the bay, averaging 3 B. and in the height of summer running as high as 5 B., enters the lowest pool through a gate that is opened and closed automatically by the tide; from this pool it is raised by a pump, having a capacity of 11,000 gal. per minute, to the highest pool, from where it gravitates to all the other pools. Any pool can be cut off from the system for harvesting, repair, or other purposes. A series of well-planned ditches protects the crystallizing pools from dilution by fresh water other than that which actually falls upon them.

Concentration by evaporation proceeds during the whole year, and the salt is harvested in the autumn months. The first salts to fall out of solution are the carbonates of iron and lime, which commence to precipitate when the brine reaches 7 B.; sulphate of lime starts to precipitate at 15 B., sodium chloride at 25°B., and a slight precipitation of magnesium sulphate occurs at 29 B. At 34 B. a critical point seems to be reached, the liquid declining to 33° with the precipitation of large quantities of magnesium sulphate and small amounts of potassium chloride, magnesium bromide, and magnesium chloride, together with double chlorides and sulphates of magnesium and potassium. If the evaporation is continued to 37 practically only magnesium chloride remains in solution. It is considered good practice, therefore, when a pure sodium chloride is the objective, as at these works, to keep the concentration of the brine below 30 B. The magnesium salts accumulate in the solution until a point is reached when further concentration would cause the precipitation of magnesium salts with the sodium chloride, so, at this stage the brine is run off into the bittern water pools. This has to be done two or three times during the year. The following is an average analysis of the bittern water:

	%		%
Sodium chloride	7.53	Magnesium bromide	0.24
Potassium chloride	2.85	Magnesium sulphate	5.53
Magnesium chloride	13.03	Ferrous sulphate	0.06

Prior to the flood, the bittern water was further concentrated, magnesium sulphate and a low-grade common salt recovered, and the liquor, which contained mainly magnesium chloride, was mixed with magnesium oxide, sawdust, pigments, and sand, and, under the name of 'durostone' or 'woodstone', was used extensively for kitchen sink-boards, kitchen and bathroom floors, and other places where either waterproof or fire-proof flooring was required. A considerable amount of this material was used in the various buildings at the Panama-California International Exposition, and it gave excellent satisfaction. Since the flood, the works in which this material was made have not been re-built, and at present the bittern water is run into the bay. This seems to be a pity, as, apart from the oxy-chloride cements, at many other works the bromine content is economically recovered, and there seems to be no good reason why it should not be recovered at Chula Vista.

When the salt is ready for harvesting, the liquor is drawn off and the salt, much of which is in large cubic crystals, is broken by picks, shoveled into light side-dumping steel cars of one ton capacity, transferred to the washer and stacker by means of gasoline power, and dumped into a series of hoppers. The hoppers are then opened, letting the salt into a trough below, along which it is moved by a screw-conveyor to a chain-bucket elevator, which drops into a long washing-box filled with a 15 B. salt solution from one of the pickle ponds—thereby dissolving as little of the salt as possible in washing—thence to a basket belt that takes it up an incline to the top of a high trestle, where it is screened, sized, and dumped into separate heaps according to size. After the salt is lifted in the wire baskets from the washing-box it is deluged with strong brine and on the way up the incline it is sprayed by a series of fine jets of pure water, thus rinsing off the 'mother liquor', or strong brine, and facilitating the drying and curing of salt in the stack. All the washings, which besides magnesium salts contain a considerable amount of sodium chloride, run back into the evaporating-pools. The salt is taken from the heaps, sized again in a portable bumping-screen operated by a cam, and is then ready for the market. The company produces an exceedingly pure article; the analysis of the salt harvested last fall running:

	%		%
Sodium chloride	99.75	Magnesium chloride	0 07
Calcium sulphate	0.09	Insoluble matter	0 03

The company is planning to keep the salt from contamination during storing and shipping by laying a paved or cement base over the ground upon which it is stacked.

All the machinery is operated by electricity, supplied by the San Diego Consolidated Gas & Electric Co. A loop line of the San Diego & Arizona railroad runs through the property, and this, when the line is completed, will materially facilitate shipping to such interior points as Imperial Valley, southern Arizona, New Mexico, and western Texas. Within a year the company will be making all grades of table, dairy, and packer salts, and also bricks and blocks for stock, and it is endeavoring to arrange for a subsidiary company to handle the bittern water, in the same way that it did before the flood destroyed the 'durostone' works.

Mill Improvements at Calumet & Hecla

Six units of the Hecla mill, stamping conglomerate ore, have been re-modeled. The slime made is treated by flotation, replacing the round-table system. Re-modeling of the Calumet plant is under way. A flotation plant to treat slime from the re-grinding plants will be ready early this summer. On its completion, all conglomerate will be subjected to either flotation or leaching with ammonia as a final treatment. No. 1 re-grinding plant is finished and employs 24 Hardinge mills in place of 48 Chilean mills. Last year this plant treated 1,245,664 tons of 0.599 to 0.868% copper tailing, at a cost of 4.33 to 6.75c. per pound. The leaching works treated 1,005,015 tons of 0.535% tailing, recovering 76% at a cost of 7.71 cents.

Hemet Magnesite

By F. B. RONEY

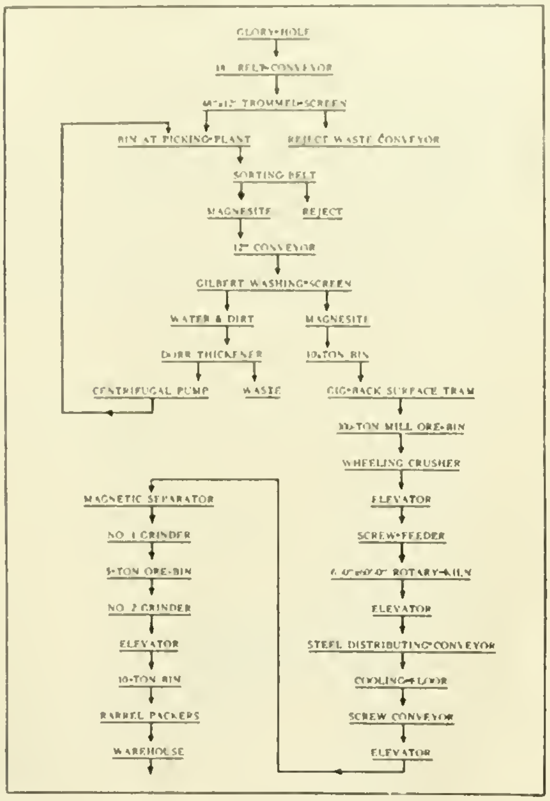
The stoppage of magnesite shipments from Austria and Greece during the War stimulated the mining of Western magnesite, notably in Washington and California. One enterprise that has been running continuously is the magnesite mine seven miles from Hemet, in Riverside county, California; this was opened some twenty years ago and operated intermittently in a small way. Several years ago a calcining and grinding plant was built, and the ore was handled at the mine by steam-shovel and tram-cars. The latter proved too expensive and was abandoned by the company then in control.

The property is now operated by Innis, Speiden & Co., of New York, under the direction of the Wellman-Lewis Co. of Los Angeles, designing and constructing engineers. A glory-hole method of mining is used. The magnesite is found in narrow veins forming a stockwork in a mass of serpentine. A shaft has been sunk to meet a raise from an adit. The overburden and orebody are blasted into the shaft and removed through the adit on an 18-inch belt-conveyor, passing over grizzlies and revolving screens. The intermediate material containing most of the magnesite is discharged into a large ore-bin. From here it is run onto a 30-in. belt-conveyor, the magnesite being picked off by hand and the residue carried by belt-conveyors to the dump. From the picking-room the magnesite is conveyed by belt to the washing-plant, which consists of a perforated revolving cylinder on an incline by which the ore descends against a heavy stream of water, which removes sand and clay. It is then carried down the mountain by gravity tram-cars to a storage-bin, holding 300 tons, at the mill.

In the calcining-plant the ore passes through an 8 by 12-in. Wheeling crusher and is then fed into the kiln by an elevator and screw-conveyor. The kiln is of the usual rotary type, 6 ft. diam. by 60 ft. long, lined with fire-brick, and revolving once per minute. It is fired with oil of gravity 18° to 20°B. under an air-pressure of 50 to 60 lb., the oil being heated in coils to 180°-250° F. At present the magnesite is being burned to a weight of 800 grammes per litre on the barreled product. The temperature required to reach this result is a bright cherry-red. No pyrometer tests have been made. Samples are taken from the furnace once an hour, or oftener; they run somewhat higher in weight than samples from the other barrels after grinding. Allowance is made for this difference in the burning to reach a weight of 800 lb. per barrel. Taking the weight per litre is a quick test and is occasionally checked by determining in the laboratory the CO_2 remaining after the calcining. The real running-test, however, of the furnace-heat is the eye. It may be noted that the magnesite leaving the furnace is considerably finer than the raw ore entering it. The change that takes place in the furnace appears to be a purely mechanical one, the CO_2 bursting the pieces of ore and passing up the stack, leaving the MgO in a porous condition easily broken with the fingers, which, by the way, is a test for good magnesite.

From the furnace the calcined ore is carried by elevator and drag, to be distributed on an inclined cement cooling-floor holding five carloads. Under this cooling-floor is a tunnel containing a long screw-conveyor. The material is shoveled through small openings controlled by slides into the trough-conveyor and passed by elevator and belt to a bin over the coarse grinder. As more or less iron is liable to get into the ore between the glory-hole and the grinding-machines, an electro-magnet controlled by a small dynamo is placed just over the last belt-conveyor, which picks off iron and saves damage to the machines.

The No. 1 is the New Process Grinder made at Potterville, N. J., and is set to grind to the size of wheat. No. 2 is the Sturtevant Rock Emery Mill made at Boston, and is set for 98% of the product to pass a 100-mesh sieve. Two Howes Barreling Machines made at Silver Creek, N. Y., take care of the product. A sample is taken from each barrel. The character of this product is indicated by the average analysis of 10 burns, as follows:



FLOW-SHEET OF MAGNESITE SORTING AND CALCINING-PLANT

Screen	Weight per litre	CO_2	MgO	SiO_2	CaO	Fe
98.03	801	1.35	83.08	14.46	0.36	0.25

The alumina was not determined. The product is especially low in lime and iron. Four cars per month of the finished product are shipped. Nine electric motors of the Westinghouse and Fairbanks-Morse types furnish power throughout the property. The dump is estimated to contain between 400,000 and 500,000 tons.

The Gold-Quartz Lodes of Porcupine, Ontario

By ELLSWORTH Y. DOUGHERTY

INTRODUCTION. The Porcupine district is in the province of Ontario, Canada, about 100 miles north-west of the older silver district of Cobalt. Mining activity began with the discovery of the Dome lodes in 1909. During the stress of unfavorable economic conditions in the past few years such important mines as the Hollinger Consolidated and the McIntyre-Porcupine have maintained production and paid dividends. The shrinkage system of mining has been applied with success; timber consumption is relatively small; the mines are cool and comparatively dry; the ore is well adapted to cyanidation. Mining operations have been carried more than a thousand feet from the surface in several mines, and the diamond-drill has proved ore for many hundreds of feet below this horizon. The Hollinger property with reported reserves in excess of $40,000,000[1] and others with smaller reserves will no doubt maintain Porcupine's position as the premier gold-producing district of Ontario for many years.

GENETIC FEATURES OF THE OREBODIES. The gold is won from pyritic gold-quartz lodes[2] in pre-Cambrian schists, and, since diabase dikes referred to Keweenawan[3] age cut the lodes, gold deposition itself undoubtedly took place in pre-Cambrian time. Enrichment or other alterations referable to descending meteoric waters are either insignificant or totally lacking. No secondary auriferous mineral masses are found cutting those of an earlier period. The occurrence of such diagnostic minerals as tourmaline and feldspar with abundant coarsely crystalline and fluid-enclosing ore-quartz has led to the classification of the orebodies as high-temperature deposits,[4] formed under great depth and pressure[5] through the agency of igneous activity.

THE LODE-FISSURES. Along the plane of the orebodies, the country-rock is frequently sheeted, unusually fissile,[6] or separated by marked shear-planes. In places one of the latter may constitute a wall of the lode. In many occurrences it may be difficult to distinguish the structure controlling the disposition of the ore-minerals from the normal schistosity[7] of the rock.

A significant structural feature of the orebodies is the complexity and multiplicity of systems of adjacent discontinuous surfaces of dislocation marking the attitude of ore-minerals. These surfaces may vary from well defined shear-planes traceable for 40 ft. or more along the strike and the dip to mere quartz-filled microscopic fissures.[8] A great capacity for differential movement was inherent in the rocks. This produced zones of intricate and closely-spaced surfaces of differential movement rather than single major breaks—an important point. If this phenomenon be considered carefully, it will be seen that it is related on the one hand to decided dislocation associated with faulting, and on the other to the close rock-mineral adjustments that produce schistosity; in other words, that it is a process intermediate in character between faulting and schist-forming adjustments.

THE LODES AND LODE-COMPONENTS. The more important properties occur along parallel zones, the longer axes of which strike east-northeast. One of these zones includes such mines as the Porcupine Crown, Vipond and North Thompson, Hollinger, McIntyre, Schumacher, and Newray; another embraces the Dome Lake, West Dome, Dome, and Dome Extension properties. These zones mark the major lode-systems, within which the minor lode-systems occur in parallel series. See Fig. 1 and 2. Within the lodes, parallel series of quartz lode-components characteristically occur. See Fig. 3, 4, 5, and 6. Each of the larger lode-components may itself be composed of smaller elements of quartz and schist.

SCHISTOSITY AND FAULTING. Fig. 1 illustrates in section the typical relations between the three main elements of structure, namely, the schistosity, the lodes, and the thrust-faults. The general rule is that the lodes truncate the schistosity though cases are found, as in Fig. 3, where

[1] 'M. & S. P.', March 1, 1919, p. 303.

[2] Following a distinction between veins and lodes defined by one of the earlier leaders of mining geology, S. F. Emmons, the term 'lode' is applied to the orebodies of Porcupine. Emmons wrote: "The term 'vein' should be confined as far as possible to a single mineralized fissure or the orebody formed along a single fissure, while the term 'lode' is applied to an assemblage of ore-bearing fissures so closely spaced that the ore that has been formed along and between them may in places be considered to form a single orebody. "Text of Folio 39, U. S. G. S., 1899." An assemblage of closely spaced quartz-bearing fissures separated by bands and masses of mineralized (usually pyritized) country-rock, the entire mixture constituting an orebody, is the typical feature of the Porcupine lodes.

[5] W. H. Emmons, 'The Principles of Economic Geology', p. 424; 1918.

[6] That is, divided into very small, closely-spaced, discontinuous partings, as distinguished from the more pronounced surfaces of dislocation, designated as sheeted surfaces.

[7] Strictly defined, 'schistosity' is a structure by virtue of which the rock may be cleaved along parallel planes determined by the parallel arrangement of the constituent minerals.

[8] It is not improbable, as suggested by microscopic study, that stresses in the rocks directly responsible for the larger surfaces of shearing also produced chemical re-arrangements and 'flow-cleavage' in the wall-rocks.

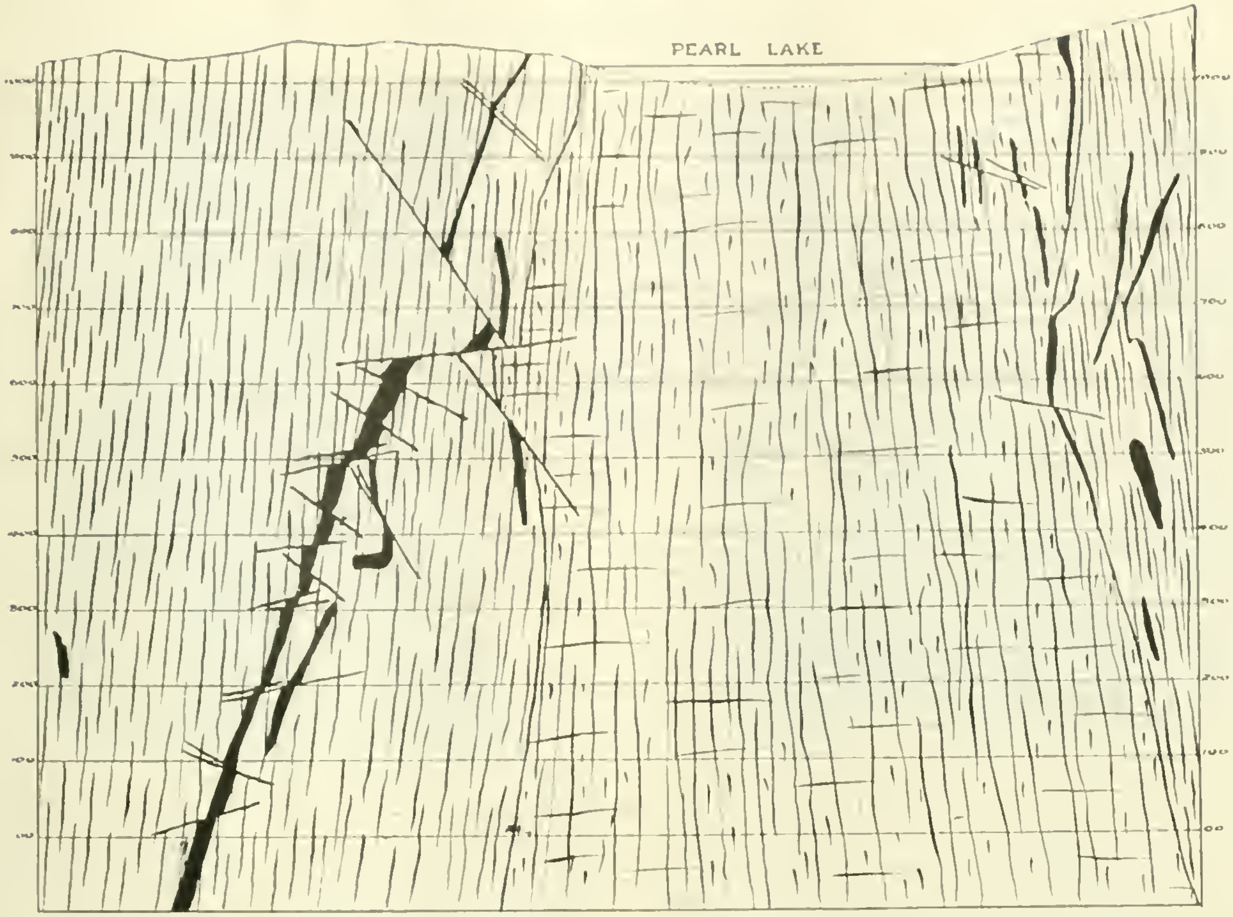

FIG. 1. CROSS-SECTION THROUGH McINTYRE MINE, LOOKING EAST

Regular broken lines: carbonate and chloritic schist. Long and short broken lines: Quartz-porphyry sericitic schist. Solid black: Lodes. Solid lines: Fault traces. Scale about 250 ft. to the inch

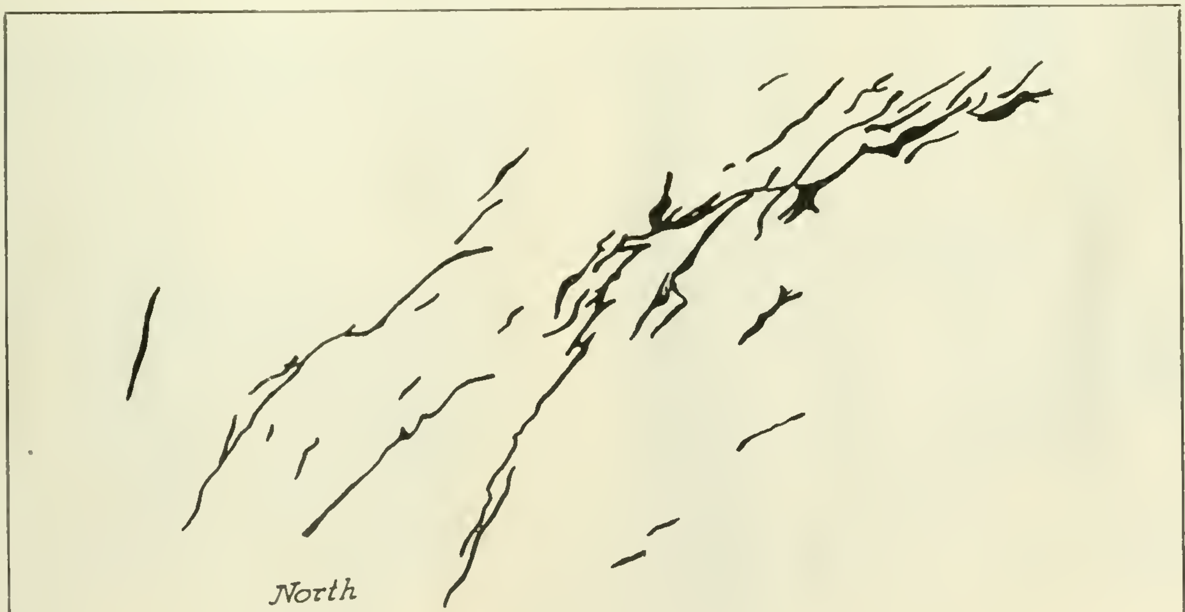

FIG. 2. PLAN OF LODE-SYSTEM ON THE 425-FT. LEVEL OF THE HOLLINGER MINE

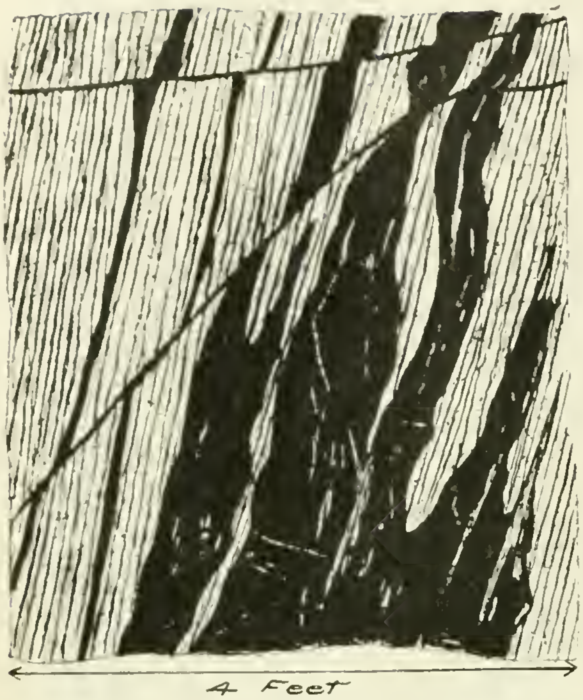

FIG. 3. DETAILED SKETCH OF LODE IN FISSILE SCHIST, ON THE 300-FT. LEVEL OF THE McINTYRE-JUPITER MINE

The section is normal to the strikes of the lode-components and the lode. Solid black: Quartz and some carbonates. Fine lines: Fissile chloritic schist in part pyritic. Heavy lines: Fault traces.

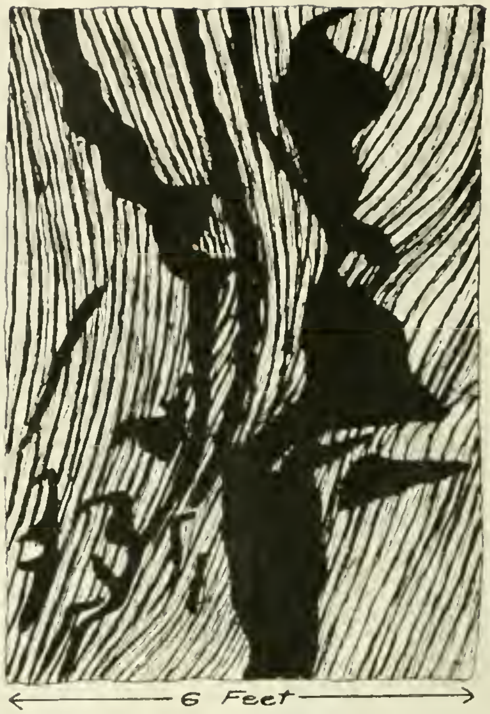

FIG. 4. DETAILED SKETCH OF LODE IN CONTORTED SCHIST, ON THE 1000-FT. LEVEL OF THE McINTYRE MINE

The section is normal to the strike of the lode-components and also roughly normal to the general strike of the lode. Solid black: Quartz Curved lines: Contorted quartz-porphyry sericitic schist.

FIG. 5. DETAILED SKETCH OF LODE, ILLUSTRATING INTERSECTING THE LODE-COMPONENTS, ON THE 600-FT. LEVEL OF THE McINTYRE MINE.

Solid black: Quartz and some carbonates. Irregular fine lines: Chloritic schist in part pyritic The section is normal to the strikes of the lode-components and also roughly normal to the strike of the orebody

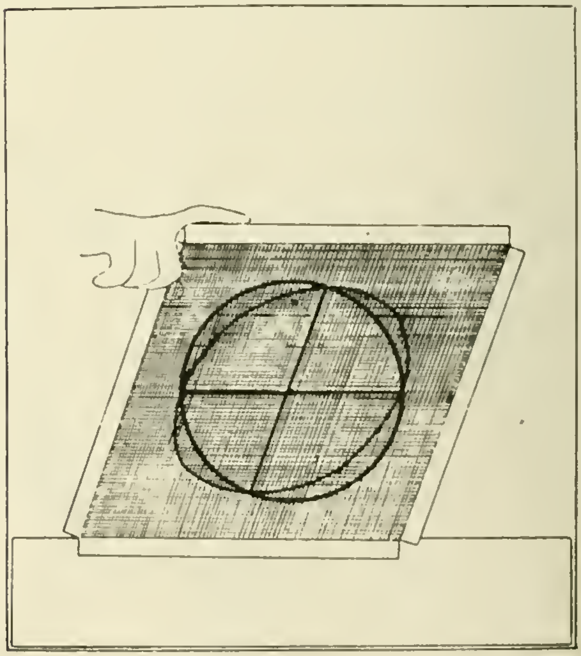

FIG. 8. EXPERIMENTAL DEMONSTRATION OF ROTATIONAL STRAIN OR SHEAR

(After C K Leith)

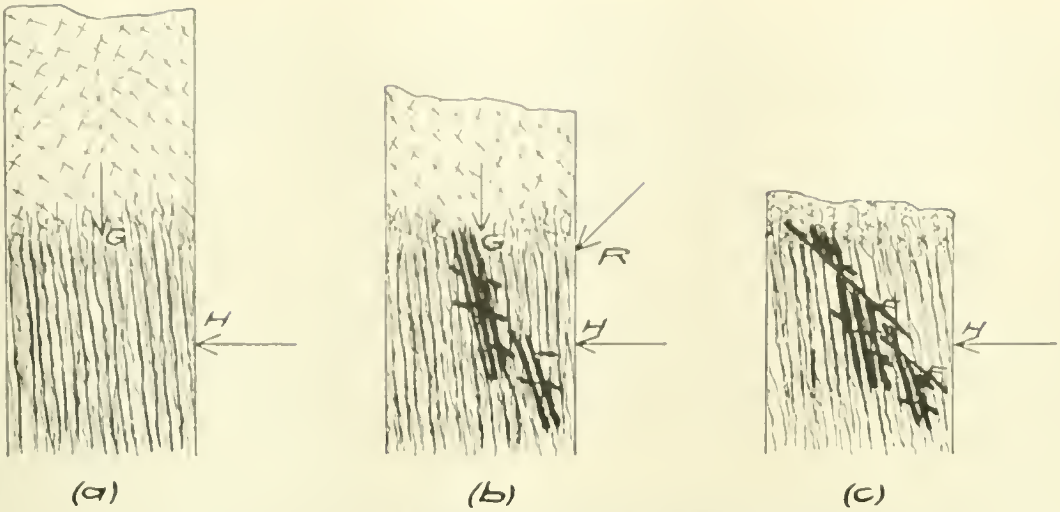

FIG. 7. DIAGRAMMATIC REPRESENTATION OF SUCCESSIVE DYNAMIC STAGES

(a) Schist-forming stage. (b) Shearing stage. (c) Faulting stage.

the quartz lode-component appear to parallel the schistosity or a shearing parallel with the schistosity. Again, as shown in Fig. 4, the quartz lode-components partly parallel the schistosity and partly cut across it. It is clear, in the majority of instances, that the ore-solutions have been diverted along sheared surfaces which exerted a more efficacious control than the schistosity. It is clear also that this shearing was superimposed upon the schistosity, and therefore was developed subsequently.

The faults dislocate the lodes; they are therefore post-mineral. Of several hundreds studied by me, all are upthrust in character, that is, the segment of lode on the hanging-wall side of the fault has moved upward with respect to the segment on the foot-wall side of the fault. A nearly horizontal movement is not uncommon.

The lode-fissures therefore were developed later than the schistosity, and earlier than the faults. The agency that produced all three phenomena was clearly a recurrent or continuous compressive stress, namely, a tangential earth-thrust. A fundamental difference in the environment of the rocks at the times this stress was acting is indicated by the variations in the character of the deformations; the progressive decrease in the weight of the overlying rock-mass is suggested as the most generally applicable cause of these variations.

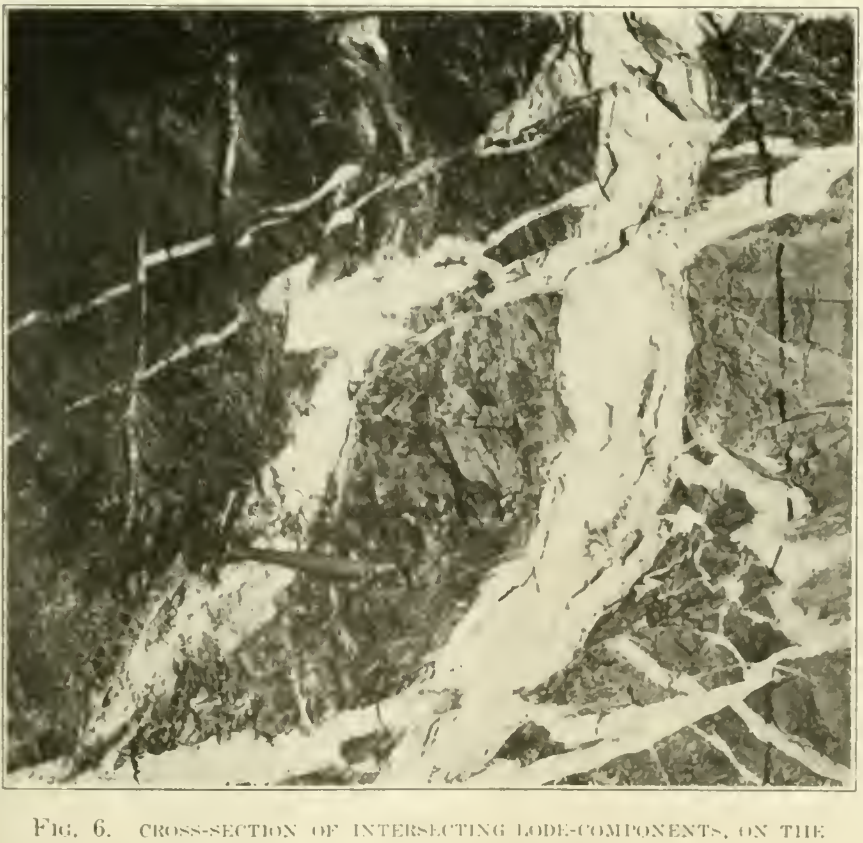

FIG. 6. CROSS-SECTION OF INTERSECTING LODE-COMPONENTS, ON THE 400-FT. LEVEL OF THE NEWRAY MINE

White is quartz. Country-rock is greenstone-schist. The pick-handle is 16 in. long

ORIGIN OF THE LODE-FISSURES. Fig. 7 represents diagrammatically the three stages of schist-forming, shearing, and faulting. *H* is a principal axis of horizontal (tangential) pressure; *G*, the weight of the superincumbent load above the particular rock-mass now exposed to view in the mines. The third principal axis of stress may be considered as acting normal to the plane of the paper. The relative force along the three principal axes of stress would be reflected in the attitudes of the resultant surfaces of dislocation.

In (a) *G*, the weight of the superincumbent rock-mass is greater than the breaking strength of the rock and *H* far exceeds *G*. Schistosity is therefore produced. In (b) is shown a condition in which, through erosion, *G* has been decreased, the zone of rock-flowage correspondingly descends with respect to the particul rock-mass under consideration; H and G do not entirely exceed the crushing strength of the rock, the resultant being represented by R and the rock-mass is thrust horizontally, presumably over a zone of flowage. The result is the formation of shear-surfaces dominantly developed along zones and surfaces of maximum capacity for differential movement. The traces of a frequently observed combination of shear-surfaces are represented by the solid lines. This is the interpretation of the principal operative process in the formation of the lode-fissures. In (c) the operation of thrust-faulting is shown. G has now become so reduced that the application of H results in the rise of the rock-mass above F, toward the relatively free surface of the earth, according to experimental evidence on the mechanism of thrust-faulting.[9]

Variations in the rigidity of the rocks and in other factors necessarily affect the character of deformation, even in rocks horizontally contiguous. The three processes are transitional and the lode-fissures form the connecting link between the extremes.

An experimental demonstration of the operation figured in (b) is given in the extremely useful little book, 'Structural Geology'.[10] Fig. 8 is a tracing of Fig. 7 of that book. The shearing of the top of the wire-net over the stationary bottom resting on the table produces traces of shear-planes represented by the lines connecting the intersections of the circle and the ellipse. The experiment illustrates rotational strain. The analogy between these traces and the cross-sectional view of the lode-components shown in Fig. 5 and 6 is striking. The widespread occurrence of steeply inclined, and horizontal or flatly inclined, intersecting lode-components suggests strongly that the stress-strain relations shown in Fig. 8 were probably closely paralleled even in the heterogenous medium of the earth's crust at Porcupine. Since the normal direction of weakness, due to schistosity, is steeply dipping, and since this weakness existed at the time the lode-fissures were formed, it is not surprising to find a dominance of steeply-dipping lodes and lode-components especially in the more schistose rock-terrains.

Copper and Gold in Manitoba

By R. C. WALLACE

[*]For the last four years prospecting has been active in the mineral belt north of The Pas, along the Hudson Bay railway line, and in some districts north-east of Lake Winnipeg. During the whole period, especially during the last two years, the number of prospectors has been small. Notwithstanding this fact, several orebodies, which admit of operation under present difficult transportation facilities, have been discovered; while others await the coming of the railway into the mineral belt. From a remarkably rich lens of copper sulphide, ore (9300 tons) has been transported to the Trail, B. C., smelter for two seasons. Other deposits of low-grade copper sulphide, in particular the large one at Flinflon lake, can only be developed when a railway has been built and a smelter erected at the mine. A reconnaissance survey is at present being made by the Canadian National Railway authorities from The Pas to Cranberry Portage, thence to the Flinflon property, a total distance of approximately 85 miles. A railway along this route would traverse part of the mineral belt, and assist in developing several other properties. A situation that demands serious attention in connection with the initiation of copper smelting in this district is the relatively high cost of fossil fuel. It would seem that circumstances demanded that the question of electric smelting of copper-sulphide ores on an industrial scale should be studied in the interests of the development of mining in this district. Experimental work would seem to have established fairly conclusively that electric smelting of this mineral is practicable on such a scale, and that it is economically preferable to reduction by coke, where coke prices are high and electric energy readily accessible. Investigations conducted by the Dominion Water Power Branch indicate that power may be developed at Sturgeon-Weir river 35 miles distant, or on the Churchill river 60 miles away, from the Flinflon property. There seems little reason to doubt that a copper industry of considerable importance will be established in this district, with probably large ore-reserves which it will be necessary to mine on a narrow margin of profit, if the price of copper should decline to pre-war quotations.

When conditions established by the War, and adverse to the gold-mining industry, are removed, several gold properties will be developed, more particularly in the Wekusko Lake area, which has fairly satisfactory service by the Hudson Bay railway and Government wagon-road. It is expected, however, that prospecting for gold will now be carried on over a much wider field, and that the Pipestone and Cross Lake areas and the belt on the south of the Hayes river, will, for the first time, receive the serious attention of prospectors. The first and greatest need is undoubtedly the trained prospector; for him the mining field is now an attractive one. The second is sufficient capital—and a large amount will be needed—to establish the copper industry on a secure basis. When both needs have been met, northern Manitoba will become an important factor in the mining industry of Canada.

DIVIDENDS paid by mining companies in Rhodesia last year amounted to £615,640 ($2,997,000). The total cash disbursements to the end of 1918 was £6,902,987 ($33,479,000). The Globe & Phoenix led last year with £165,614, followed by the Shamva with £90,000, Lonely Reef with £81,302, Falcon with £80,000, Eldorado Banket with £45,000, and Rhodesia Chrome with £6000.

ACETYLENE is now capable of making a 24-in. cut in an ingot. Beyond that it is necessary to use hydrogen.

[*] Abstract from Bulletin, Canadian Mining Institute, March 1919.

The Determination of Manganese: A Modification of Volhard's Method

By W. C. RIDDELL

*INTRODUCTION. The following modification of Volhard's well-known method[1] for the determination of manganese was adopted, after comparison with several other methods.[2] It has been used for some time by several analysts, for ores ranging from 10 to 60% manganese. The usual procedure recommended for Volhard's method is shortened by omission of the evaporation with sulphuric acid and the aliquoting of the solution after the addition of zinc-oxide emulsion. A number of the features of this method have been already suggested.[3]

One important advantage of the method as outlined is that the end-point is readily determined, thus shortening the time required for an analysis. The determination of manganese in an ore can be made by one operator in 15 to 20 minutes, and a series of 12 to 15 determinations in about two hours, exclusive of the time required for preparing the samples.

OUTLINE OF PROCEDURE. The weighed sample (using a 0.3296-gm. sample and 0.2 N. $KMnO_4$ solution, 1 cc. of solution = 1% Mn) is transferred to a 400-cc. beaker. 10 to 15 cc. HCl (sp. gr. 1.2) are added and the solution evaporated down to about one-half its volume. If the ore contains insoluble manganese silicate, which can usually be determined by the pinkish color of the insoluble residue, about 1 cc. of HF is added, and the evaporation is continued until decomposition is complete. The glass is only slightly attacked by the HF, and beakers used in this way will last for some time. If the solution should evaporate to dryness, a few cubic centimetres of HCl and hot H_2O are added and heated until the salts are in solution. Dilute to about 300 cc. with boiling water, add 5 to 6 grammes $ZnSO_4 \cdot 7H_2O$ and a small excess of ZnO emulsion. Run into the hot solution an excess of standard $KMnO_4$ solution, which may be added rapidly with no great care, and determine the excess by back titration with a solution of $MnSO_4$ that has been standardized against the $KMnO_4$.

NOTES. The use of an excess of $KMnO_4$ effects a more nearly complete oxidation of the manganese in solution to MnO_2 than is accomplished by the original Volhard procedure. It enables one to add the standard $KMnO_4$ solution more rapidly than is possible where back titration is not utilized. It also causes the MnO_2 precipitate to settle rapidly and in a condition favoring the determination of the end-point. It is especially useful when a number of ores are being analyzed, the manganese content of which is entirely unknown and of wide variation. The method has also been used for slags and ferro-manganese. The addition of $ZnSO_4$ tends[4] to lessen the occlusion of MnO in the MnO_2 precipitate with consequent low results, as shown by the following experiments: 40 cc. $MnSO_4$ required 39.5 cc. 0.2 N. $KMnO_4$ when no $ZnSO_4$ was added; 40 cc. $MnSO_4$ required 40.1 cc. 0.2 N $KMnO_4$ when 5 gm. $ZnSO_4 \cdot 7H_2O$ was added; 40 cc. $MnSO_4$ required 40.1 cc. 0.2 N. $KMnO_4$ when 10 gm $ZnSO_4 \cdot 7H_2O$ was added.

Experiments to determine the effect of not removing HCl by evaporation with H_2SO_4 to SO_3 fume indicate that this procedure is unnecessary. Definite volumes of $MnSO_4$ solution were measured out and to the solution varying quantities of HCl (sp. gr. 1.2) were added. The solution was then neutralized with ZnO emulsion and titrated with standard $KMnO_4$.

Table 1

Experiment number	$MnSO_4$ 0.2 N cc	ZnO	HCl 1.2 sp. gr. cc	$ZnSO_4 \cdot 7H_2O$ gm	$KMnO_4$ 0.2 N cc
1 ...	40.0	Slight excess	2	5	40.1
2 ...	40.0	" "	5	5	40.1
3	40.0	" "	5	0	40.1
4 ..	40.0	" "	0	0	39.4

The experiments indicate that the removal of HCl by evaporation with H_2SO_4 is not necessary but that it is essential to have zinc ions present. These may be introduced by the addition of zinc sulphate or, as in experiment No. 3, by neutralizing an excess of acid with zinc oxide.

The $MnSO_4$ solution can be prepared by mixing a bottle of C. P. manganese sulphate, weighing out 1 gramme, determining the manganese as outlined, and calculating the quantity required for any desired volume. The water of crystallization in manganese sulphate varies. Ordinarily about 12 gm. in one litre will give a solution of about the desired strength for use with 0.2 normal $KMnO_4$. 1 cc. of a 0.1 normal solution of $KMnO_4$

[1] J. Volhard. Chem. News, Vol. XL, p. 207. A discussion of the Volhard method will be found in 'Sampling and Analyses of Iron and Steel', by Bauer and Deiss, translated by Hall and Williams. McGraw-Hill Book Co., New York, 1915.

[2] For a brief outline of these methods consult Circular No. 26, U. S. Bureau of Standards. 'Analysed Iron and Manganese Ores—Methods of Analysis'.

[3] See Brearley and Ibbotson. 'The Analysis of Steel-Work Materials—Bibliography of Analytical Methods for Manganese', p. 388. Published by Longmans-Green Co., 1902.

[4] Volhard. Fischer's modification of Volhard's method. Ztschr. anal. Chem., Vol. 48, 1909, p. 751; Cahen and Little. 'Analyst', Vol. 36, 1911, p. 52; Brearley and Ibbotson's bibliography.

= 0.001648 gm. manganese. Using 0.2 normal $KMnO_4$ and a 0.3296 gm. sample, 1 cc. $KMnO_4$ = 1% manganese. (This applies only to the Volhard titration.)

The following table gives some comparative results. The permanganate used was standardized with Bureau of Standards sodium oxalate:

Table II

Ore number	Analyst	Precipitated as MnO_2 with Br	Ford Williams method	Modified Volhard method as outlined	Regular Volhard method no correction factor used
1	A	37.5	. . .	37.7	37.4
	B	37.5	. . .	37.6	. . .
	C	37.6	. . .	. . .	. . .
2	A	47.9	47.8	47.8	47.6
		47.9	47.8	47.75	47.7
		. . .	.	48.0	. .
3	A	57.9		58.3	57.8
	B	. . .		58.4	. . .
4	A	22.5		22.5	22.3
5	A	. . .		56.4	. . .
		. . .	.	56.1	55.7
		. . .	. . .	56.2	55.8
	B	. . .	. . .	56.0	55.5

Ore No. 5—Bureau of Standards manganese sample No. 25. The manganese value of this ore given by the Bureau of Standards is 56.4% Mn. Blum[5] later determined the manganese by the bismuthate method, and gives the value as 56.2-56.3% Mn.

One of the most convenient and accurate methods available for standardizing $KMnO_4$ is by the use of the Bureau of Standards' sodium oxalate. The value of the standard $KMnO_4$ may also be determined by analyzing a weighed sample of the Bureau of Standards' standard manganese sample No. 25 according to the procedure as outlined and calculating the value of the solution in terms of manganese.

Electrolytic Zinc Improvements

In the annual report of the Judge Mining & Smelting Co. of Park City, Utah, the superintendent of the zinc plant, J. T. Ellsworth, makes the following remarks:

The year 1918 was one of continuous alterations and improvements, particularly in the electrolytic department; as a result only one-third capacity was attained for practically the full twelve months. Inability to obtain necessary chemicals for purification of solutions made it necessary to carry on prolonged experimentation to find substitutes. This has now been done and operation will be practically free from the chemical market. On account of men going into the Army, the general effect on efficient operation of the plant was harmful, as experienced men are necessary.

The original form of electrolytic cells with rotating cathodes were found inefficient and expensive, and were therefore replaced during the year by stationary cells with rectangular anodes and cathodes—much simpler cells—and by which the trouble due to warping of plates and poor contact of cathode-plates are largely overcome. The stripping cost per pound of zinc is also considerably reduced.

On account of scarcity of water, the first unit of these cells was operated without any cooling-device, but as this was found to be impracticable, a spray cooling system was put in operation late in December. This enables the temperature of the cells to be controlled individually, which is an important advantage, as there is always a certain amount of current used up by resistance not due to the zinc-sulphate solution itself, and this energy must be dissipated as heat, which, if not carried away from the cell, causes re-solution of the deposited zinc from the cathode-plate.

Provision was made for grinding concentrate. This will increase the plant recovery of zinc by practically eliminating the large quantity of sand product, which has represented a considerable proportion of the zinc treated, the coarse material not being capable of receiving a proper roast and therefore is unattacked by acid, and a complete loss.

The plant is now producing spelter of highest purity, and while some improvements are still necessary, they are chiefly mechanical, and a consistent and gradually increasing production may now be expected.

Tunneling at Park City, Utah

To eliminate shaft-sinking, hoisting, water difficulties, and the surface transformation of ore and supplies, also to develop its property, the Silver King Consolidated company is driving the Spiro tunnel. The size of the tunnel is 8 by 8 ft., with a ditch 3 by 4 ft. The advance during 1918 was 4001 ft., making a total of 9001 ft. The present depth from the surface is 1300 ft. The daily rate was 10.9 ft. The greater part of the distance has been in 'Woodside' shale, but in October last year this formation gave place to limestone, alternated by bands of shale. The preliminary geological work on the tunnel has so far been unusually correct, according to the consulting engineer, H. A. Lee. In the 4001 ft. driven during 1918, timbering was required in 1960 ft., also temporary stulling after each blast before the broken rock could be removed. At one point, for 300 ft., the ground required 10-in. timbers set at 4-ft. centres, instead of 8-in. timbers at 5-ft. centres. The lower stratum of the red shale was tough and springy. It drilled easily, but required 22 to 24 holes, heavily loaded, to break to the bottom of the holes. The following is a comparison of costs:

	1918 4001 ft.	1917 5000 ft	Total length 9001 ft
Labor cost, per foot	$18.63	$13.52	$15.74
Material cost, per foot	11.86	8.10	9.77
Total	$30.49	$21.62	$25.51

The totals for 1918 were $74,528 for labor and $47,450 for supplies.

Before entering the shell or drum of a boiler for cleaning or inspection, be sure the air is pure, or at least that there are no explosive gases in the shell. If zinc-plates are used to prevent pitting by the water, the chances of an explosion from the mixture of hydrogen and air are great if exposed to an open light.

REVIEW OF MINING

PLATTEVILLE, WISCONSIN

Factors Affecting Zinc, Lead, and Pyrite Production.—Need for Making High-Grade Blende.

During March, markets were irregular and unsatisfactory, but fairly good weather and fair roads enabled many operators to make good yields and shipments. A comparison of prices paid to Missouri and Wisconsin zinc miners shows that the latter was given a slight advantage, by reason of their nearness to the smelters in Illinois. The fine outputs and deliveries last month are due to certain factors at work in the Wisconsin field, tending ultimately to centralize zinc mining here into a few hands. Independent ore producers of any size, determined to remain in the game, have arrived at the conclusion that existence depends on being able to convert the low-grade concentrate into one of high-grade ready for immediate reduction on arrival at the smelter. For this reason, producers lacking the facilities for making a high-grade product, have been shut-out; and the March record, during a rather off season, is credited to fewer mining corporations equipped with refining plants or associated directly with subsidiary organizations so provided. The initial cost of erecting refining plants at mines is so great at present that before long the large concerns operating in this field will absorb the smaller producer entirely, and shipments to smelters will in time be made up exclusively of high-grade blende, assaying 60% zinc or better.

Prices for high-grade refinery product held at the beginning of the month at $45 per ton, base. Some ore sold at above this figure. The price held steadily until the 22nd, when the first break in many months was registered, the price receding to $42.50, at which level it closed the month. On second-grade product more irregularity was shown, the price moving from $41.50 to $42, $41, and $40 per ton. Low-grade producers where unprotected on open-market offerings through lack of contract agreements, were shut-out of the market entirely, and several suspended production.

Lead-ore producers found offerings for their product steady and fair, but little ore reached market. $60 for 80% concentrate held most of the month, but such ore as did clear was sold at figures under the ruling quotation. The Flint Mill & Furnace Co., a new smelter at Wauwatosa, Wisconsin, using oil-fuel, entered the field as a buyer, but its presence failed to create much interest. It appears that the price is the thing that counts. Good weather enabled many miners out of employment to enter shallow and surface deposits, making a fair extraction of ore. The reserve in the field at the close of the month was over 1000 tons.

Pyrite shippers had a discouraging month, although shipments of acid from local plants were normal. Prices were unsatisfactory to ore refiners, from whom most of this class of ore is now obtained. The reserve in the field is conservatively estimated at 5000 tons.

Gains were made in production of zinc-carbonate ore. The price averaged $27 per ton, 40% zinc content. Independent producers shared but little in the continued high price for this product. Such carbonate as is mined here is used almost exclusively in the manufacture of zinc oxide, and the Mineral Point Zinc Co. is not finding as ready a market for it as formerly, and has large stocks.

Deliveries of concentrate in March, from mines to refining plants in the field, and from mines to smelters direct, were:

	Zinc, lb	Lead, lb
Benton	18,674,000	550,000
Galena	4,954,000	82,000
Mifflin	3,872,000	......
Highland	2,360,000	234,000
Hazel Green	2,232,000	68,000
Shullsburg	848,000	76,000
Cuba City	678,000	......
Platteville	192,000	.....
Linden	50,000	......
Total	33,860,000	1,010,000

The gross recovery of crude concentrate, from mines, amounted to 17,624 short tons; net deliveries to smelters, out of the field, 10,084 tons.

TORREON, MEXICO

Notes on the Smelter at Torreon.

Ownership of the smelter of the Compania Metalurgica de Torreon has passed out of the hands of the Madero family to a syndicate of Mexican capitalists, according to a recent authoritative announcement. This plant, which is at Torreon, is said to be the largest independent smelter on the continent. The company was organized October 10, 1900, and the plant was finished and placed in operation two years later. It is equipped with nine blast-furnaces for reduction of lead-silver ore, each having a capacity of 115 tons daily. Besides these, there is a 250-ton copper-furnace and a copper-converter good for 15 tons per day. During the three years immediately preceding the beginning of the Madero revolution, the Torreon smelter treated 770,518 tons of ore, valued at ₱24,077,063. The smallest tonnage was recorded in 1909, due to the scarcity of silicious ore available. In 1907, 1908, and 1909 the value of exports in the form of silver-lead bars was ₱30,526,840. Originally the Torreon smelter company was capitalized at ₱1,250,000 and started operations with only four furnaces, establishing agencies at Parral, Chihuahua, and Guanacevi. From the first it provided comfortable homes, schools, and the conveniences of a modern hospital and drug-store for its employees. In 1903 the capital was increased to ₱1,750,000 and two furnaces were added to the plant. Though invited under flattering conditions to join the smelter trust, the company steadfastly declined and remained independent. The Torreon smelter treated in its second year of activity 140,495 tons of ore, making a profit of ₱701,049. In 1904 it increased its capital to ₱3,500,000, in that year adding two furnaces and treating 201,612 tons of ore at a profit of ₱629,370. In 1905 there was treated 238,326 tons at a profit of ₱700,944. Still another furnace was added to the plant in 1906, this for treatment of copper ore, and in that year there went through the plant 259,552 tons of ore, upon which the profit was ₱775,286. Later there was erected a 150-ton concentrator at the company's San Diego mine at Santa Barbara, Chihuahua, producing daily 50 tons of 40 to 50% zinc concentrate. The last increase in capitalization was made in 1907, when the total was raised to its present status, ₱5,000,000. Ernesto Madero was president of the company.

Dividends paid by the Torreon smelter were 20% in 1902, 18% in 1903, 14% in 1904, 12% in 1905, 12% in 1906, and 6% in 1909. Declining dividend percentages were due to the steadily increasing capitalization throughout this period. No dividends were declared in 1907 and 1908, because in those years a large reserve-fund was provided for, and early bonds of the company were redeemed.

CRIPPLE CREEK, COLORADO

General Notes on the District.

Labor conditions are about normal again, more miners seeking employment.

The Excelsior company, operating the Longfellows of the Stratton estate, is mining a high average grade of ore between the fifth and sixth levels. During March, nearly 200 tons sent to the Golden Cycle mill, mined from a vein 10 ft. wide, assayed better than 5 oz. gold per ton, the last settlement being $74.40.

The Modoc company in March shipped from the Last Dollar mine on Bull hill 350 tons of ore, worth from $18 to $38 per ton.

A sacked consignment of ore from the Mary McKinney mine on Raven hill was settled at $2367 per ton. The gold content was 88 oz. and silver 600 oz. A 35-ton lot shipped at the same time averaged 5 oz. gold.

The Chesapeake claim, adjoining the Portland on the eastern slope of Battle mountain, owned by the Cripple Creek & Chesapeake Gold Mining Co. of Boston, has been leased to John L. McLean of Victor. The property has lain idle for 15 years or more.

Lessees of the United Gold Mines in March shipped 1000 tons of over 2-oz. ore from the Trail and Bonanza mines.

JACKSON, CALIFORNIA

Argonaut Mine Fire Out, and Damage Nominal.—Road Construction in the County.

On April 12 the bulkheads closing the Argonaut and Muldoon shafts of the Argonaut company were removed, and men entered the mine. The fire discovered on the 4000-ft. level of the Argonaut shaft on March 27 is believed to be out, and men who went down as far as 3900 ft. say that the hoisting-station on that level appears to be uninjured and the fire did not reach the shaft. There is evidence of a cave about 80 ft. back from the 3900-ft. station, and doubtless the burning of timbers in the stopes above 4000 ft. has resulted in a great deal of caving. Fears were entertained that the shaft would be lost, and for a while there seemed small hope that the hoist at 3900 ft. could be saved, so the reports made on the 12th are most gratifying. The Muldoon mine is connected with the Argonaut shaft on the 2400-ft. level, and as soon as the blowers there could be started, the gases reached the surface through the Muldoon shaft. The condition of the shaft and levels below 3900 ft. has not yet been investigated, as the air is still bad. It is expected that the cessation of pumping after the bulkheads were placed has allowed the water to rise far enough to cause some damage on the lower levels of this deep mine, but the early resumption of work on the usual scale is contemplated. In order to extinguish any fire that might have been smoldering in the mine, carbonic acid gas was forced into the shaft before the bulkheads were removed. This alone is said to have cost the company not less than $12,000. The cost of catching up caves, unwatering the lower levels, and restoring the property to its former condition is difficult to estimate, but all interested are well pleased at the prospect of operations being resumed at this rich mine with so little loss of time. Great credit in the handling of the trying situation is due the general manager, N. S. Kelsey, the chief mine inspector, H. M. Wolflin, officers of the Industrial Accident Commission, and the U. S. Bureau of Mines rescue-teams. [On April 14 it was reported that smoke was again coming out of the Argonaut shaft.]

At the Kennedy mine adjoining the Argonaut the fume from the fire made work on the various levels unsafe, and all operations there ceased shortly after the Argonaut shaft was bulkheaded, with the exception of pumping and shaft repairs. The danger now appears past and miners returned to work there on Saturday last.

Road construction, which means much to the mines of Amador county, is now well under way, four trucks and a number of men being employed on the wagon-road from the cross-county highway at the summit of Sutter hill to the Ruggles saw-mill above Pine Grove. Ruggles, who has large timber interests in the eastern part of this county, as well as in Calaveras county, subscribed $10,000 for this work on condition that the County Supervisors would expend $5000. The opening of this road should ensure ample timber for the mine at reasonable price.

TORONTO, ONTARIO

Blue Sky Bill Withdrawn.—Re-Opening of Dome Mine.—Kirkland Lake Railway.

A serious menace to mining in Ontario has been averted by the withdrawal of the 'Sale of Shares Act', commonly known as the 'blue sky law', proposed by the Ontario government. It was a drastic measure intended to protect the public against fraud by the sale of worthless shares, but in the form in which it was drawn up would have greatly checked legitimate investment, and prevented expenditure of capital by men willing to take speculative chances on new and improved prospects. The main feature of the bill provided for the appointment of a commissioner, whose permission must be obtained before shares in a company were offered for sale. The announcement of the intended introduction of this measure was met by so strong an opposition from the mining industry that the Government presented the bill in a modified form, exempting mining companies from its operation, and intimating that it would probably not be passed this session.

Porcupine.—It is officially stated that the Dome Mines company will resume milling operations on April 1. Erection of the large underground crusher continues, and is expected to be completed in about a month. The working-staff has been largely reinforced.

The Porcupine Crown has been unwatered and mining operations resumed. There is enough $10 ore broken to supply the mill at capacity for six months.

Kirkland Lake.—The Temiskaming & Northern Ontario Railway Commission will begin construction of a branch line seven miles in length from Swastika to Kirkland Lake, at an early date.

DIVIDE, NEVADA

Brief Review of This New District.

Out of the dozens of companies organized to operate in this district, at least thirty are doing exploration work; but beyond the already rich developments in the Tonopah

Divide, to a depth of 465 ft., the opening of milling-ore at 500 ft. in the Brougher Divide, and the following of some good seams in the Gold Zone, Gold Wedge, and one or two others, nothing has been found, certainly nothing to justify the rapid rise and high prices of shares dealt in by the San Francisco Stock Exchange. Calculating on the number of shares issued and their present prices, in any of the Divide companies, none of the developments represent a net value equal to the market-value.

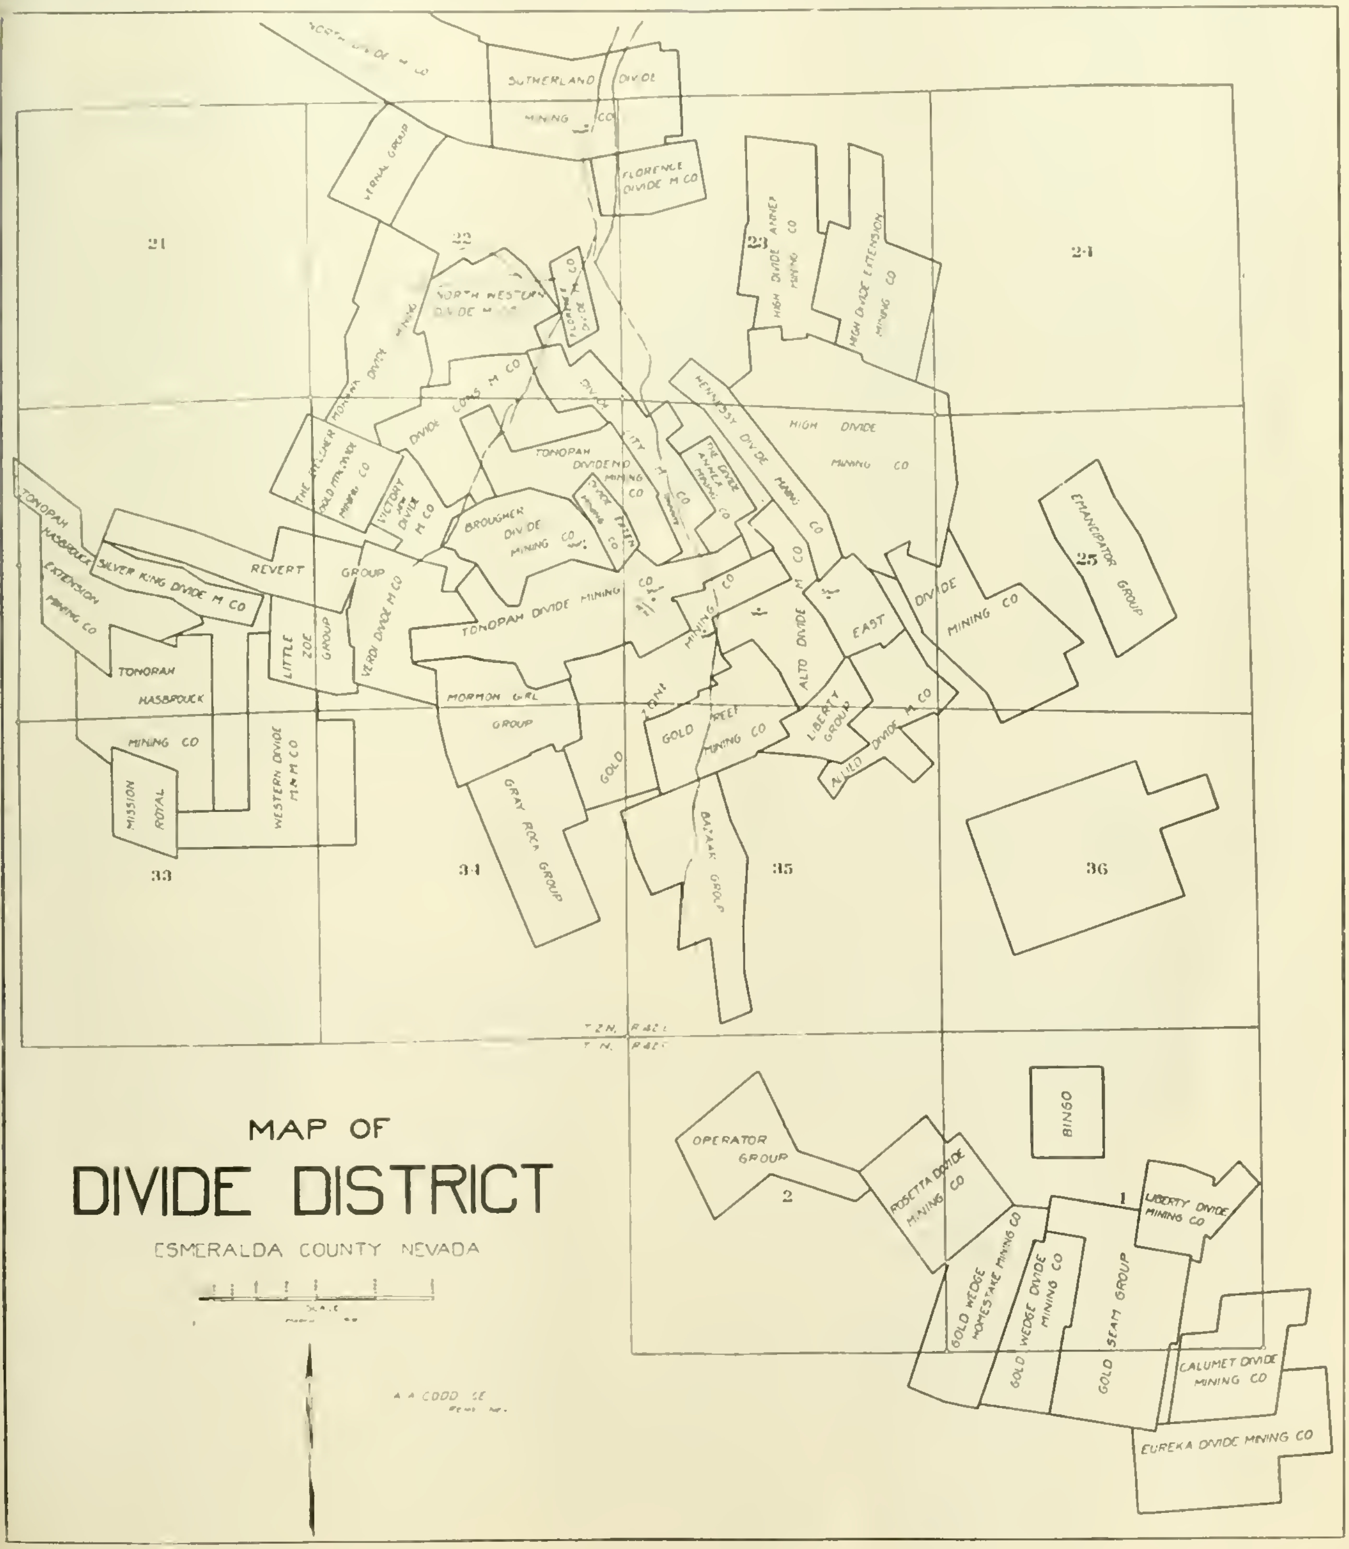
A full face of ore has been showing for over a week in the Brongher, at a distance of 135 ft. from the main cross-cut on the 500-ft. level.

The Tonopah Divide last week sent 420 tons of ore to the MacNamara mill at Tonopah. It is said that the mill-heads assay from $29 to $18 per ton, but an average of $35 is to be maintained for better treatment. A large compressor that was at the Goldfield Merger mine is being erected.

The Hasbrouck is re-opening workings done years ago on the 200-ft. level.

The Gold Zone, on the 500-ft. level, has driven south-east about 500 ft., with reported improved conditions. A 30-in. face on April 12 is said to have assayed $85.70 per ton. F. A. Burnham is manager.

Some of the other prospecting companies are the Emancipator, Hennessey, Keystone, Smuggler, Harmill, Reno, and Ben Hur, all with Divide attached to their names.



THE MINING SUMMARY

ALASKA

In Professional Paper 109 of the U. S. Geological Survey, the Canning River region (70° N. lat. and 146° long.), in northern Alaska is discussed in 251 pages by E. de K. Leffingwell. On page 178 the author gives brief notes on the mineral resources. From a prospector named Arey, who had lived in that country many years, Mr. Leffingwell gained a good idea of the possibilities. The general conditions of climate, isolation, and transportation are such that even if parts of the region are mineral bearing the chances for their development are not favorable, and it is not likely that they will attract prospectors. A few fine flakes of gold constitute the only definite evidence of any occurrence of valuable minerals. A seepage of oil and some coal outcrops were found in the western part of the Arctic Slope region. There are no trees or bushes, but there is ordinary tundra vegetation. In summer there is sufficient grass for a party with 6 horses. The barren-ground caribou is easily the most important animal, both for food and clothing. The reindeer has thrived in Arctic Alaska, but their number has not grown with the demands of the country. There is grazing ground enough for millions of reindeer. There are also foxes, mountain sheep, polar and other bear, whale, seal, ducks, ptarmigan, and fish. Useful hints on living and traveling in this region are given.

Juneau.—Alaska Gastineau in March treated 183,550 tons of 76.9-cent ore, recovering 76.3%. The first quarter of 1919 totals 497,465 tons, against 469,698 tons in 1918, the latter being over 15 cents higher grade.

Kennecott.—The Mother Lode Coalition Mines is to be incorporated in Delaware, with 2,500,000 shares of no par value. The Kennecott Copper Corporation will hold 51%. Shareholders can exchange their shares for those in the new company on the basis of one share ($10 par) of Mother Lode Copper Mines Co. The new company will pay off the old company's $500,000 bonds and provide a working capital of $1,000,000.

Valdez.—The Harmon Machinery Co. of Cordova, G. A. Harmon manager, has taken an option on the Big Four mine on Mineral creek. The new operators are called the Alaskan Hercules Mining Co. C. M. Anderson is to be in charge. A mill was purchased at Seattle recently.

The Cache Creek Mining Co. has increased its holdings, and will start hydraulicking as early as possible.——The Cache Creek Dredging Co. is to erect a hydro-electric plant for its boat

ARIZONA

Duncan.—The Ash Peak Mines Co., 9 miles west of this place, has opened a considerable quantity of silver-sulphide ore, and it is reported, contemplates the immediate erection of a 100-ton cyanide-plant.

Gunsight.—The Gunsight Gold & Tungsten Mining Co.'s mill is being overhauled, new and heavier stamps being erected. The mill is to be leased to L. Tiel to treat the Tiel & Sullivan ores. The plant will be able to treat custom ores from the district

Oatman.—The United Eastern pays 7 cents per share, $95,140, on April 28. This makes $1,581,080 to date.

The Tom Reed company in March produced gold valued at about $77,000. Most of the ore is from the Aztec claim, mixed with a little from the Gray Eagle and Bald Eagle claims. Net profits are said to be about 3 cents per share monthly, say $27,000.

CALIFORNIA

Idria.—New Idria Quicksilver Mining Co. in 1918 produced 10,700 flasks of mercury, a decrease of 300. Sales of metal realized $1,311,394. Operations, depreciation, and depletion amounted to $1,101,205, and the net profit, subject to Federal taxation, was $167,540. Current assets total $398,743, and liabilities $256,684. The San Carlos and Idria mines are both in good condition. Five rotary-kilns, a plan of which was shown in the 'Press' of January 4, 1919, were completed by April 1, 1919. They have a total calcining capacity of 400 or 500 tons daily. Electric power is to be available in the spring. Twenty new dwellings and a 4000-bbl. oil reservoir were built. The report leaves much to be desired. As the average price for qicksilver in America last year was $118, the company must have sold about 11,100 flasks, taking some from stock. At $68 per flask for costs in 1917, as given by the manager, H. W. Gould, to the Federal Tariff Commission, there was a profit of about $50 per flask, or a total of $555,000. Even a cost of $75 per flask in 1918 would give a total of $477,000. From what source the large amount of construction work done was paid is not stated.

Plymouth.—The Plymouth Consolidated in February treated 10,200 tons of ore yielding $58,000. The profit was $16,000. On the 2450-ft. level the west drift at 380 ft. north is out 102 ft., the last 56 ft. assaying $8.50 per ton across 52 inches.

Winthrop.—The assay-office and administration office of the Bully Hill Mines were burned on April 7. The loss was $8000. The oil-flotation plant escaped damage. The offices will be re-built.

IDAHO

'A Preliminary Report on the Mining Districts of Idaho', Bulletin 166, by Thomas Varley, superintendent of the Salt Lake mining experiment station of the U. S. Bureau of Mines, and others, has just been issued. In 1917 the Bureau and the University of Idaho arranged to co-operate in an investigation looking to the improvement of mining and milling methods in the mining districts of that State, with a special view to the wider development of the mineral deposits and greater efficiency in the treatment of the low-grade ores. This work has been made possible largely through the generosity and active assistance of the mine operators, especially certain companies in the Coeur d'Alene region.

As the first step in the work under the co-operative agreement, it was decided to gather all data possible on the various mining districts throughout the State, both active and abandoned, in order to ascertain their potential possibilities, special attention being paid to methods of metallurgical treatment and to the solution of the many metallurgical problems in order to effect a greater commercial saving. With this plan in veiw, field work was begun in the

latter part of May 1917, and was continued during the summer. E. K. Soper, formerly professor of mining, University of Idaho, and now dean of the mining department of the Agricultural College at Corvallis, Oregon, visited the mining districts in central and south-western Idaho, also some of those in the northern part of the State. D. C. Livingston, professor of geology in the University of Idaho, at Moscow, also visited some of the mining districts in central Idaho during the summer; in addition, much valuable information he had gathered on former trips to many other districts is included in this report. Credit is also due Mr. Livingston for the maps covering the State, as well as the bibliography at the end of each chapter. Thomas Varley spent a short time in the field, principally in the mining districts in central and northern Idaho, and made a brief visit to the south-western districts with Mr. Soper. The field work of C. A. Wright, metallurgical engineer of the Bureau, in direct charge of the co-operative work, was chiefly in the Coeur d'Alene region. Mr. Wright visited nearly all of the districts in the region, and devoted most of his time to studying milling methods.

The bulletin aims to give the localities of the various mining districts, and the nature of the present operations and those that have been carried on in the past. The writers do not wish to imply that all districts mentioned in this bulletin were visited during the summer of 1917, for a great deal of the material has been gathered from other reports, especially from publications of the U. S. Geological Survey. However, it is hoped that this report will be of help to those who are interested in mining in the State of Idaho. The plan is to continue the field work and subsequently publish the results of the investigations in much more detail, with greater emphasis given the metallurgical treatment of the ores and the problems involved. Copies of this bulletin may be obtained by addressing the Director of the Bureau of Mines, Washington, D. C.

Adair.—The Richmond M. M. & R. Co. shipped 8 cars of 14% copper ore during February, and 5 cars in March. This output is defraying all expenses. B. N. Sharp is manager.

Elk City.—According to W. O. McNutt, secretary of the Elk City Good Roads Association, in a letter to the North-west Mining Association at Spokane, the acting-director of the U. S. Department of Agriculture, Bureau of Public Roads, states that it is hoped to begin the survey of the south fork of the Clearwater River road soon, and to follow with construction as soon thereafter as possible. This road will make accessible an important undeveloped gold belt.

Wallace.—According to the 'Miner', although several of the larger properties are closed, there are several development companies about to resume operations. Some of these are the Carbonate Hill, Copper King, Grant Ledge, Cedar Creek, Bullion, Lucky Swede, Columbus, and Chicago-Boston.

MISSOURI

Joplin.—Production of the Tri-State region last week was as under:

State	Blende, tons	Calamine, tons	Lead, tons	Value
Kansas	1,179	...	201	$53,321
Missouri	989	263	62	......
Oklahoma	5,981	...	1,466	321,219
Total	8,149	263	1,729	$423,491
Average price	$40	$27	$60	......

The total value was $103,000 less than the previous week.

MONTANA

Butte. The March output of Butte & Superior was 7,250,000 lb. of zinc and 135,000 oz of silver, about half of normal capacity

Hassel.—The Iron Mask mine is to be developed by a long cross-cut tunnel, which will cut the vein at a depth of about 700 ft. The shaft is 350 ft. deep, and produces silver-lead ore. The mine is 9 miles from shipping point at Townsend

Helena.—The Lebannon group of claims at Granite Butte, 40 miles north-west of this place, has been sold for $20,000 The gold ore is suitable for cyanidation.

Thompson Falls.—The Montana Power Co., which supplies power to many mining companies in this State, and in Idaho, also for over 400 miles of the Chicago, Milwaukee & St. Paul Railroad, reports gross earnings in 1918 amounting to $7,558,741. In 1917 and 1916 the respective totals were $6,905,256 and $6,219,148. Preferred shares received $677,026 and common $1,916,208. The hydro-electric plants generated 1,108,125,350 kw-hr., an increase of 17%. The connected load at the end of 1918 was 301,825 kw., a gain of 7%. New construction cost $750,000. Additions to the Thompson Falls and Holter plants call for the issuance of $2,836,000 bonds.

NEVADA

Goldfield.—The Goldfield Development Co. is proceeding with its plan to open and mill the large tonnage of $5.60 ore in the Combination mine. Among this is 100,000 tons of $7 ore, which may be treated first.

The Atlanta is still cross-cutting at 1900 ft.——The Kewanas is driving from the bottom of a winze from the 840-ft. level.——Grandma is driving north-west at 830 ft. to open a cross-vein in quartz formation.——Great Bend is prospecting at various points.——In the Merger, the cross-cut from the main south-east drift on the 910-ft. level of the Spearhead is well into the Merger.——The Spearhead has driven an incline raise over 100 ft. from the south-east drift on the 910-ft. level to reach the shale-latite contact.——Red Hill Florence is driving and raising at 600 ft.——On the 320-ft. level of Cracker Jack, 6 ft. across the winze gives low assays in gold.——The important work in the Silver Pick is at 700 ft.——The Lone Star is sinking to the contact, believed to occur at shallow depth at this point.

Jarbidge.—The Jarbidge Nevada Mines Co., of which O. B. Olson, of Tacoma, is president, has taken a lease and option to purchase the Alpha mine and stamp-mill. This property is on the south side of Bourne gulch, 2000 ft. east of the North Star mill. A good deal of Alpha ore was treated there. At depth the vein is wider, with an increase of sulphides. The silver content has increased, but the gold remains about the same. A Wilfley table was put in to concentrate the sulphide ore, and several tons of concentrate was sent to the smelter. The Jarbidge Nevada owns the Legitimate mine, adjoining the Alpha on the north. The two will be worked together and their ores treated at the Alpha mill. Miners are cleaning out the Legitimate tunnels. The lowest—Starlight tunnel—starts on Bourne creek, just above the quartzite dike. It is 1650 ft. long. At 1500 ft. it was expected to cut the Starlight vein, which is still missing. It is believed that a raise will be driven at the 1500 ft. point. There is an extensive fault in Starlight hill. The faulted block is 1600 ft. wide at right angles to the fault movement. The Legitimate fault-plane marks the south edge of the faulted block, and the foot-wall of the Flaxie vein marks the north edge of the block. The faulted block is not considered deep-seated. The Starlight tunnel cut the Legitimate fault-plane, giving much water. This drained the Legitimate mine, which is higher in elevation and 1500 ft. east. Carpenters are completing the aerial tram that is intended to carry the Starlight ore to the Longhike mill. Work is progressing on the lowest North Star tunnel, the portal of which is 250 ft. south of the North Star mill. Development work has been resumed on the Elmore 2 and 3 claims.

Pioche.—There is said to be some excitement over recent discoveries of rich silver-lead ore in the Harvey mine, a mile east of this place. Donahue & Stindt are the lessees.

Goodsprings.—The mill at the Galena Canyon is to go into commission before the end of April. The mine has been developed under the management of John P. Broker. The five-mile pipe-line from a well in Sandy valley to the mill is completed. Carl Schlutz of Los Angeles is president and Henry Gross, secretary of the company.

The old mill at the Yellow Pine has been dismantled and new machinery erected in the building. Debris from the recent fire at the mine is being cleared away, and the mine and mill will be operated with full crews shortly. It is stated that the new plant permits of treating larger amounts of ore with a higher recovery.

OREGON

Homestead.—According to D. M. Drumheller, Jr., recently returned to Spokane, the region between the Iron Dike mine and the Seven Devils country, 300 to 400 square miles in extent, in Baker county, has great possibilities as a copper producer. Lack of transportation is the main hindrance to exploitation. The Oregon Short Line enters from Huntington, in a northerly direction, but goes no farther into the belt. The town of Homestead is 135 miles from Lewiston, Idaho, and both being on the Snake river, Lewiston becomes a logical point in the route for the construction of a railroad to Portland by water grade. The railroad company is repairing its tunnel at Ox Bow, four miles from Homestead. Fire destroyed the timbers and released a large quantity of loose material that filled the tunnel, which is half a mile in length. Approximately $500,000 is being expended in the restoration. Concrete is being used. The Iron Dike is using trucks for hauling its concentrate to Ox Bow in the meantime. The big orebodies were formed along the mineralized sheer-zones and usually where intersected by an intrusion, such as a dike. The Iron Dike mine is of this form. Little high-grade veins are found all through the country. In addition to copper, Homestead contains a little silver and gold. The Iron Dike employs 60 men and is operating its mill at capacity, which is 125 tons daily. Operations have been proceeding for several years with highly profitable results, it has been stated. Other properties under development are the Copper Syndicate, McCarty, Copper Queen, Olympia, and Red Ledge. Spokane capital is considerably interested in the region.

TEXAS

Burkburnett.—A well is to be sunk here to a depth of 5000 ft. by Harry Byrens of Fort Worth.

UTAH

Salt Lake City.—The Utah Copper Co. has filed suit in the U. S. District Court to recover $158,520, alleging that tax assessments levied by the County Assessor and tax collector on tailing from reduction mills at Garfield were made without authority of the law.

Tintic.—Chief Consolidated pays 6½ cents per share on May 1. This amounts to $57,471, and makes $1,402,873 to date.

The North Standard company is equipping its mine with a new electric hoist, compressor, machine-drills, and other machinery. The new two-compartment shaft is down 85 ft., the rate of sinking being 4 ft. daily. This will continue to 500 ft. J. H. Manson is in charge.

MEXICO

Chihuahua

Batopilas.—The Lluvia de Oro Mining Co., operating south-west of this place, has suffered almost no interruption during the past three years. A stamp-mill and cyanide plant are treating the rich gold ore. L. Underwood is manager.

PERSONAL

Note. The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

E. P. Matheson is visiting Anaconda.

N. H. Emmons, 2nd, is at New Orleans.

C. H. Hulbert sailed for Manila on April 10.

W. W. Mein has arrived here from Nicaragua.

Oliver E. Jager, temporarily residing at Corvallis, Oregon, has been in San Francisco.

Joseph T. Terry, Jr., has opened an office as consulting metallurgist at Salt Lake City.

John F. Coats, of Vancouver, B. C., has been examining mines at Placerville, California.

Arthur O. Gates, Lieutenant in the U. S. Navy R. F., arrived in San Francisco on the 'Marblehead'

Carrol F. Reece, Lieutenant in the 102nd Infantry, has been awarded the D. S. C. for heroism in battle.

D. H. McDougall, president of the Nova Scotia Steel & Coal Co., has been elected president of the Canadian Mining Institute.

Jay A. Carpenter, recently in charge at Belmont for the Nevada Wonder company, is now superintendent of the Ben Hur mine at Divide.

L. Salazar, director of the Mexican Geological Institute, is visiting San Francisco to study the work of the California State Mining Bureau.

Harold Cogswell, formerly engineer and metallurgist at the Original Amador Consolidated mine, now Captain in the 316th Engineers, is on his way home.

F. V. Smitnoff, who is traveling for capitalists operating in Russia and Siberia, was at Salt Lake City last week. He inspected the Utah Copper Co.'s properties.

Charles W. De Witt has resigned as mine superintendent for the Chicksan Mining Co., in Korea, and is now at Omsk, Siberia, in the service of the U. S. Government.

E. H. Clausen has been discharged as Captain of Engineers in the U. S. Army, and is now associated with the Mine & Smelter Supply Co. at its New York office.

L. H. Rand and **B. H. Wadsworth,** of Oakland, members of the California Debris Commission, recently returned from an inspection of the Omega dam near Washington, Nevada county, California.

Edward W. Berry and **Joseph T. Singewald** have been appointed by Johns Hopkins University to study the geology and mineral resources of the Central Andes in Bolivia and Peru. Mr. Singewald's work 'Mineral Deposits of South America', written with **Benjamin L. Miller,** of Lehigh University, has just been published.

The U. S. Civil Service Commission at Washington, D. C., announces an open competitive examination for a coal-mining engineer at $2400 to $4000, and assistant at $1800 to $2400 per annum. Competitors will not be assembled for examination but will be rated on education, professional experience, and essay, publications, or reports (to be filed with application). Under the first two subjects competitors will be rated upon the sworn statements in their applications, and upon corroborative evidence adduced by the Commission.

The Utah section of the American Institute of Mining and Metallurgical Engineers gave a banquet at the Hotel Utah on April 7. The affair was attended by 150 members and guests. Informal addresses were delivered by Horace V. Winchell, of New York, president of the Institute, C. K. Leith, James F. Kemp, and Senator Reed Smoot.

THE METAL MARKET

METAL PRICES

San Francisco, April 15

Aluminum-dust, cents per pound	50—60
Antimony, cents per pound	8
Copper, electrolytic, cents per pound	15½
Lead, pig, cents per pound	5¼—6¼
Platinum per ounce	$100
Quicksilver, per flask of 75 lb.	$75
Spelter, cents per pound	8
Zinc-dust, cents per pound	12½

EASTERN METAL MARKET

(By wire from New York)

April 15.—Copper is inactive and easier. Lead is dull and weaker spelter is lifeless and lower.

SILVER

Below are given official (not Government) quotations, in cents per ounce, of silver 999 fine. In order to make prompt settlements with smelters and brokers, producers allow a discount from the maximum fixed price of $1.01½, hence the lower price. The Government has not fixed the general market price at $1 but will pay this price (as from April 23, 1918) for all silver purchased by it. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange. On August 15, 1918, the Treasury announced that the maximum price was fixed at $1.01½ per ounce. The British government fixed it maximum at 49½ pence, on September 2, but on November 12 this was changed to 48¾, on December 13 to 48 7/16, and on February 20 to 47¾ pence. On March 25, on account of the low rate of exchange, the London price was adjusted, with a minimum of 95 cents, resulting in daily fluctuations.

Copper production of the large mines during March was as under:

Mine	Pounds	Mine	Pounds
Anaconda	13,900,000	Miami	4,551,115
Arizona Copper	2,800,000	New Cornelia	2,134,000
Calumet & Arizona	3,736,000	Old Dominion	2,574,000
East Butte	1,700,230	Phelps Dodge group	8,331,000
Greene Cananea	3,200,000	Shattuck (mine closed by fire)	2,452
Inspiration	6,700,000		

Phelps Dodge net earnings in 1918 were $15,045,683, compared with $22,456,906 in 1917. Dividends were the same, $10,800,000.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Date					
Mch.	18	68.00	Apr.	1	68.00
	25	68.00	"	8	67.50
				15	75.00

June	85.50	112.00	....	Dec.	117.42	115.00	....

During February there was imported from Mexico 244 flasks of quicksilver. Exports amounted to 366 flasks, of which 265 went to Japan, and 50 to Hongkong. Most of the remainder went to Denmark and Norway.

In 'Quicksilver in 1917', advance chapter of 'Mineral Resources of the United States', by F. L. Ransome, will be found a good deal of useful information on this metal.

LEAD

The A. S. & R. Co. reduced its price of lead from 5¼ to 5 cents on April 9.

The National Lead Co., manufacturers of lead oxides, lead products, type metal, bearing metal, painters' materials, and chemicals, made a net profit of $4,692,815 during 1918. Dividends totaled $3,048,333. The surplus is $16,659,907, a decrease of $3,018,333. The company has 7286 shareholders, an increase of 134.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound:

TIN

Prices in New York, in cents per pound. The monthly averages in 1918 are nominal. On December 3 the War Industries Board fixed the price to consumers and jobbers at 72½c. f.o.b. Chicago and Eastern points, and 71¼c. on the Pacific Coast. This will continue until the U. S. Steel Products Co.'s stock is consumed.

The tin smelters now in operation in this country and their approximate annual capacity are as follows, according to the U. S. Bureau of Mines March report:

	Metallic tin, tons
American Smelting & Refining Co., Perth Amboy, N. J.	10,000 to 12,000
Williams Harvey Corporation, Jamaica Bay, N. Y.	6,000
Eastern Metal Refining Co., Charleston, Mass.	700

The market for tungsten concentrates was further depressed during March, and some sales were made at considerably less than the prices quoted ($10 per unit) for February. Most, if not all, of the producers have closed down. At a meeting held in New York during March, a committee was appointed to represent the industry as a whole and to effect a working agreement among all the interests involved, for mutual protection.—H. C. Morris in March report of U. S. Bureau of Mines.

The price of American fertilizer potash varied during March from $3 to $3.75 per unit. Muriate, of 80% grade, in bags, averaged $200 per ton during the month; and sulphate, basis 90%, was $275 per ton, but fell to $225 toward the end of the month.

Eastern Metal Market

New York, April 9.

The markets are all quiet, with the tone in some of them easier than a week ago. Buying of all metals is light.

Antimony has advanced in a quiet market.

Copper demand has fallen, but prices are fairly firm and unchanged.

Lead is quiet with prices unchanged nominally.

Tin is still stagnant and without feature.

Zinc demand continues light, but prices have firmed because of economic conditions in the market.

ANTIMONY

The market is quiet and demand is light, but quotations are higher at 6.62½ to 6.75c., New York, duty paid, for wholesale lots for early delivery.

ALUMINUM

No. 1 virgin metal, 98 to 99% pure, is quoted at 29 to 31c., New York, for early delivery. The market is featureless.

COPPER

The activity in evidence most of last week and the week before has subsided, and demand has fallen off. There is still some inquiry with some business being done, and the recession is regarded as largely temporary. Prices are unchanged, with electrolytic quoted at 15.37½c., New York, and Lake copper at 15.62½ to 15.87½c. While export demand is not large, it is interesting. There have been fair sales of wire-bars in foreign countries during the past few weeks, mostly to England and at prices substantially above domestic levels. It is believed that there is no established export-price, but it is anything that anyone can get. An interesting development is the trading in copper on the New York Metal Exchange. Yesterday, 600 tons were sold for delivery in the next six months at 100 tons per month at the flat price of 15.75c. per lb. In fact, each day since this new procedure was adopted there has been a little business done, the results showing what dealers think of the future prospects. A good start is believed to have been made in copper trading on the Exchange, despite the fact that some has been disappointing so far.

LEAD

The market continues dull with prices unchanged at 5.25c., New York, or 5c., St. Louis, for early delivery. These are nominally correct, but there has been in the last few days a little under-selling by one or two interests, restive under the present inactivity. These sellers have offered early delivery metal at 5.20c., New York, and it is probable that a little business was done, but not much. The leading interest (A. S. & R. Co.), and the outside market continue to quote the same level. February exports of lead were 6847 tons. [On the 9th, the trust price was lowered to 5c.]

TIN

The tin market is the same old story—featureless, stagnant, and still held down by Government restrictions. The nominal price is still the one of 72.50c., New York, but there is almost no buying, and it is now practically impossible to purchase even American tin, the sales of this having been stopped about a week ago. The entire situation is one of 'watchful waiting', and little progress seems to be in process in disposing of allocated metal. There has been some buying of tin for future shipment for storage in England or in Canadian ports against the removal of import restrictions, but this has been small. Tin has been offered recently as low as 47.50c. for April-May shipment from the Straits. When Government restrictions are lifted an active market is expected—one that may become even wild until the situation adjusts itself. So far no arrivals have been reported in April. The London market yesterday for spot Straits was £226 10s. per ton.

Tin smelters now in operation in the United States have a yearly capacity of 18,700 tons of metallic tin. They are the American Smelting & Refining Co., 12,000 tons; the Williams Harvey Corporation, 6000 tons; and the Eastern Metal Refining Co., Charlestown, Massachusetts, 700 tons.

ZINC

Because of a reduction of $1 per day in the wages of employees at Western smelters and because of the prospect of strikes as a result of this, quotations have gradually stiffened until yesterday prime Western for early delivery was quoted at 6.30c., St. Louis, or 6.65c., New York. There have been less strikes and fewer shut-downs than expected, it is stated, and now there is a softening tendency until it is claimed that the metal can be bought at 6.27½c., St. Louis, for April or early delivery. Demand is not large and consumers continue to be shy, though dealers are more active. The unsettlement in the steel price situation is one cause, there being less immediate prospect of buying by galvanizers. It is stated that Government stocks of zinc, mostly high grade, will be disposed of in the same manner as the copper stocks, sales to be made over the next 15 months. This metal is said to be less than originally estimated, a press report today giving it as 93,346,000 pounds.

ORES

Antimony: Importations of ore from Chile in February were in quantities containing 3008 lb. of metal, with an amount from Peru in the first half of March having a metal content of 9276 lb. Quotations are not obtainable.

Manganese: Of the total February imports of 21,819 long tons, 11,619 tons came from Cuba and only 5450 tons from Brazil. It is interesting also that 2240 tons came from Japan and 1950 tons from Argentina.

Manganese-Iron Alloys: While the quotation of 80% ferro-manganese is still $150, delivered, re-sale alloy has sold as low as $115. Production in the United States in March was close to 20,000 tons, bringing the total for the first quarter to about 63,000 tons—a large output considering conditions. Added to this is the importation of British alloy, which has been nearly 7000 tons this year to March 15, with about twice as much yet to come. Spiegeleisen is quoted at $40 to $45 delivered. Demand for these alloys is hand-to-mouth.

Molybdenum: The market is quiet and inactive, with quotations nominal at about 80c. per pound of MoS_2 in the 90% concentrates. Imports of ore in February were 68,599 lb., valued at $48,255, most of it from Canada. There were no imports in the first half of March.

Tungsten: A leading broker reports that a fair quantity has changed hands during the past week. No quotations, however, are published or obtainable from other sources. The market is depressed and most, if not all, of the producers have closed down. In the first half of March, imports of tungsten-bearing ores were 393 tons, valued at $242,189. There were no ferro-tungsten imports. The mineral investigators of the U. S. Bureau of Mines state that as a result of a questionnaire the average loss of tungsten in making the ferro-alloy is about 14%. This is regarded as too low, as it is believed that this is nearer 25% actually. No quotations are available on ferro-tungsten.

High-speed tool-steel is quoted at $1.70 per pound.

Company Reports

GOLDFIELD CONSOLIDATED MINES CO.

As is well known now, the property of this company has been leased to the Goldfield Development Co., which is to sub-lease sections and work other parts of the mines itself. The twelfth annual report covers the year 1918, and the following notes are from the statements of the secretary, C. F. Burton, and general manager, E. A. Julian:

Financial Statement: the net income last year was $796,410. Operations resulted in a loss of $7801, but on adding other items, and charging off $350,000 on the Montana Mines Co., the total loss was $324,381. Depreciation amounted to $193,380. Undivided profits on December 31, 1918, were $1,880,816, including $136,062 cash.

Dividends: none has been paid since October 30, 1915, so the total remains at $28,999,832.

Development: there was 4848 ft. of new work accomplished, compared with 16,477 ft. in 1917, and 28,333 ft. in 1916. This was nearly all in the upper levels. There is no measurable ore-reserve. Forty sets of lessees were operating on the split-check system. They mined 25,085 tons. Treatment of 2422 tons from mine dumps, averaging $2.98 per ton, resulted in a slight loss, and indicate no encouragement from the remaining 50,000 tons.

Production: the mill treated from all sources 94,654 tons of $11.25 ore, against 250,550 tons of $8.14 in 1917, and 338,680 tons of $7.52 in 1916. Extraction was 86%. In two years there was 240,715 tons of $1.27 tailing treated at a cost of 59 cents per ton, extraction being 57%. The output to date is $73,440,672 from 3,187,662 tons of ore, and $312,499 from 246,006 tons of tailing.

The Goldfield Development Co. now proposes to mine a large area in the Combination mine, and according to its general manager, A. I. D'Arcy, the following is the plan:

The vein from which the production of the Combination mine was made is an almost vertical fissure, having an average width of 50 ft. and extending from what is known as the January shaft to the boundary-line of the Florence mine, a distance of approximately 380 ft. The tonnage contained in a block of ground having the dimensions as given would be approximately 1,500,000 tons. The method formerly used in mining was by square-set stopes, and filling of the stopes with low-grade vein material known as 'gob'. A compilation of over 1000 samples taken from the filling of the stopes or 'gob' gave an average assay value of $5.60 per ton in gold. It is apparent that if a cheap mining method were put into effect upon this tonnage and grade of ore, a profitable operation would result. The Goldfield Development Co. proposes to adopt a method for the mining of this large tonnage of ore, which has been successfully used in other mines, and which has resulted in a mining cost of less than $1 per ton. Briefly, the method will consist of driving haulage-ways on a level below the 380-ft. level throughout the length of the ore-channel from the January shaft to the Florence line, and by a system of raises and chutes the ore will be drawn off and hoisted to the surface. As the Combination shaft is partly in the vein, it would be impossible to use this shaft, as when the drawing-off process was started the surface ground would cave and destroy it, so it is therefore proposed to use a shaft which was sunk in the early days and which is in good order with the exception of requiring new timbering. This shaft is approximately 600 ft. deep and 300 ft. distant from the vein. It would be necessary to drive a cross-cut from the shaft to the vein as part of the haulage-system, then extend the haulage-way for the entire length of the ore-channel. The cost of the necessary drifts, cross-cuts, raises, chutes, stations, and repairs to the shaft to adapt the Combination mine to this method of mining should not exceed $60,000, and this would be the total cost of the undertaking at the mine, as the property is equipped with hoists, air-compressors, underground electric-haulage locomotives, and in fact everything necessary for handling the large tonnage of ore. The success of the undertaking would depend on being able to handle from 500 to 1000 tons of ore per day. This could be accomplished with the equipment on hand at the mine, and as the Consolidated mill has a record for the treatment of ores in excess of 35,000 tons per month, there would be no difficulty in the treatment of the ore. As the ores of the Combination mine are particularly amenable to cyanidation, it is proposed to give the ore a simple cyanide treatment and do away with some of the processes in vogue at the Consolidated mill, such as concentrate treatment, etc., thus cutting the cost as low as possible. Before milling operations are started there will be some necessary changes and repairs at the plant, which will require an expenditure of $15,000, therefore the estimated expenditure to put the proposition on a paying basis would be $75,000. With the cheap mining method at the mine and a simple cyanide treatment at the mill, it will be profitable to handle ores of a value as low as $3 per ton, with a value in excess of $5 per ton and approximately 1,500,000 tons the undertaking should show a profit of $3,000,000, or a net profit of $1.20 per share for the entire capitalization of the company.

LIBERTY BELL GOLD MINING CO.

Property: mines and mill at Telluride, Colorado.

Operating Officials: C. A. Chase, manager; H. G. McClain, superintendent; M. L. Anderson, mine superintendent; A. J. Weinig, metallurgist; and E. J. Woodworth, accountant.

Financial Statement: the income during the year ended September 30, 1918, totaled $1,148,523 net. Operations, plus depletion $24,405, cost $837,858, leaving a surplus of $310,664. The balance on October 1, 1917, was $481,152, and after adding profit and reduction of capital, etc., and deducting depletion of ore for 1909 to 1917, and dividends, the balance carried to 1919 was $645,364. Investments are valued at $267,431.

Dividends: these amounted to $387,310, making a total of $2,594,181.

Development: the 3073 ft. of new work was a decrease of 1603 ft. All openings amount to 16 miles. The old productive areas were almost exhausted early in the year, but a partly developed area in the eastern part of the mine was further opened and equipped for motor haulage. The compressor plant had to be duplicated. As the efficiency of the men fell off considerably, it was decided to start the contract system, which improved matters greatly in costs and less waste among the ore. There has been extracted from this mine 2,141,612 tons of ore, and reserves now amount to 600,000 sq. ft., equal to 100,000 tons.

Production: the mill treated 90,700 tons, assaying 0.529 oz. gold and 2.565 oz. silver per ton, of which 98% and 85%, respectively, was extracted. Gold from cyanidation was $1,084,700, and from concentrate $68,343. The total since 1899 is $14,043,893. Underground work cost $8.83, and treatment $3.13 per ton.

EAST RAND PROPRIETARY MINES

This company has a property covering 5267 acres on the Rand, also a mill containing 820 stamps, 25 tube-mills, and cyanide plants. During 1918 there was treated 1,372,000 tons of ore averaging $5.58 per ton. The profit was 18 cents per ton. Ore-reserves are estimated at 2,200,000 tons, averaging $6.50 per ton. In 1917, 1,741,300 tons yielded a profit of 46 cents per ton. Reserves then were 4,200,000 tons of $6.10 ore.

EDITORIAL

BLUE-SKY legislation has been denied by the lawmakers of Ontario. A bill to regulate the sale of stocks and shares aroused successful opposition, largely, it appears, because the terms of enactment were so severe as to restrict legitimate financial activity. The wild-cats are purring.

IN our last issue we referred to a committee on co-operation to be appointed by the American and Canadian mining institutes. We note now with pleasure that the American Institute has appointed Messrs. E. P. Mathewson, Albert R. Ledoux, and L. K. Armstrong as representatives for the purpose, and that Messrs. D. H. McDougall, Willet G. Miller, and R. H. Stewart will represent the Canadian Mining Institute. This is an excellent selection and carries the promise of good work in furthering friendly relations between the two organizations and the two neighboring countries.

MEXICAN misrule comes again into unpleasant prominence owing to the sad news that Edward L. Dufourcq, of New York, assistant manager of the Teziutlan Copper Company, was killed on April 18 by a band of so-called Zapatistas, who waylaid him when engaged in professional duties near the plant. Mr. Dufourcq is known to many of our readers as an engineer of high character. Insult is added to injury by calling the murderers "Zapatistas." Zapata is dead; these are plain bandits. The effort to give a political color to marauding ruffians by calling them 'istas of any kind is damnable nonsense. We hope, in spite of the improbability, that the Department of State at Washington will make an immediate inquiry into this outrage and insist upon prompt punishment.

OLE HANSON has been in San Francisco. The mayor that made Seattle famous is a man after Theodore Roosevelt's own heart, and that means he is very much of a man indeed. With his family of eight children, his rise to useful prominence as a citizen, his fearless insistence on observance of the law, and a capacity to put his ideas of civic government into effect, this virile Norseman has proved himself 100% American. Most of us like men that know their own minds and follow the lead of courageous principle. There is too much of listening leadership in the world. We thank heaven, as Tennyson did, "for a man with heart, head, hand like some of the simple great ones gone"; for "one who can rule and dare not lie." Mr. Hanson recognizes that "a mass attack is being made against civilization" and that this is a time "to cast aside all prejudices, forget all party ties, and study the problems that confront us from the standpoint of American citizenship." He warned the labor-unions against the I. W. W. or Bolshevist groups, whose domination would cause Union Labor to "slip back 25 years and lose the wonderful advances it has made by honest struggle and hard work." This is good advice, and it comes from a friend of the working-man.

DELAY in starting the investigation of claims for compensation under the War Minerals Relief Act is causing anxious comment among the producers of chrome and manganese, because the mine workings, in some instances, will have caved before an examination can be made by the Government engineers. It is suggested therefore that the producers would save time and expedite a settlement of their claims by causing examinations to be made and reports to be written by mining engineers having such a standing as will command the confidence of the Government's representatives, namely, the Commission appointed for this purpose. The small expense incurred would represent less money than that entailed by the long wait likely before the Government inspectors arrive on the ground and make their estimate.

SIGNS of antagonism between Mr. Lloyd George and Lord Northcliffe are manifest. In his speech before Parliament on April 16 the British Premier made pointed reference to the publisher of many newspapers and imputed his attacks on the Peace Conference to injured vanity. In this respect, and in others more objectionable, Lord Northcliffe resembles Mr. Hearst, although he is a politer edition of that unblushing exponent of yellow journalism. Mr. George said that he would rather have "a good peace than a good press"; he described some of the difficulties under which the Conference labored, conducting its deliberations while stones fell on the roof and wild men screamed at the keyhole. The Northcliffe press is as much a curse to the democracy of Great Britain as the Hearst press is to the more advanced democracy of this country. We are glad to see Mr. George lock horns with the controller of the London 'Times', the influence of which is due largely to a tradition now exploded, and we hope that the result of this personal conflict will be to curb the sinister use of influential newspapers by an ambitious and irresponsible publisher. The freedom of the press is essential to the preservation of democratic institutions, but the license of the press ministers to a kind of unchartered power that is deadly to democracy. We look forward to the time when the President and his official family at Washington will exhibit a larger aloofness from Mr. Hearst's malignant influence.

BOLSHEVIST propaganda is said to be responsible for the emigration from this country of a large number of aliens. According to the Savings Bank section of the American Bankers Association an exodus of six million persons, taking with them four billion dollars, is probable, unless steps are taken to check the propaganda. The New York Customs House officials are said to have asserted that those now sailing from that port carry with them from $2000 to $15,000 apiece in United States currency. Also it is estimated that fully 1,300,000 persons cannot be stopped from departing and they will take four-fifths of the total currency in this country. As many as six million aliens may be lured, it is said, by the Bolshevist call. "This is very serious," says the New York dispatch issued by the Universal Service. Yes, it would be extremely serious if it were true. Our newspapers every day contain statements quite capable of robbing us of our sleep if we had to believe them. We doubt whether any such number will want to leave or could be permitted to leave for some time to come; we doubt their ability to carry away so much currency; and if they were really Bolshevists in spirit we would speed their departure with a swift kick, even if they went away with pockets bulging with money.

IN this issue we publish the first part of the Alien Property Custodian's report on the German metal octopus. We shall discuss the subject more fully at a later date; meanwhile we note that a sale of enemy holdings of American Metal Company stock was held at New York early in April and that 49% of the outstanding capital was acquired by Mr. Charles Hayden, of Hayden, Stone & Company, in behalf of a syndicate the membership of which is not disclosed. The transaction involves the payment of $1,850,160 for voting-trust certificates representing 34,644 shares out of the 70,000 issued. The sale took place under the auspices of the Alien Property Custodian, who, three years ago, seized the property of the three principal metal-dealing German firms. Mr. H. W. McAteer, representing another syndicate, bought 562 shares out of 25,000 shares of the Compania de Minerales y Metales, a Mexican subsidiary of the American Metal Company. This block of stock fetched $57,000. No change in the management or status of the American Metal Company, now in the safe hands of the Custodian, is to be made for the present. Members of the old management, still employed by the Custodian, own 27% of the stock, while the British Public Trustee, occupying a position analogous to that of our Alien Property Custodian, holds the 24% formerly owned by Henry R. Merton & Co., one of the tentacles of the German octopus.

Siberia

Dispatches from Paris state that the Omsk government in Siberia is to be recognized by the Peace Conference. This is important news and most gratifying. Amid the chaos of Russian misrule the establishment of order in Siberia has been the one hopeful sign. It will be remembered that early last year Admiral Koltchak, formerly commander of the ill-fated Black Sea fleet, seized the reins of administration and established a government, with the support of the Siberian and Czecho-Slovak troops. At a national conference held at Ufa, in the Ural, a program for the unification and regeneration of Russia was accepted. This program was upset by Admiral Koltchak's *coup d'état* and in its place a government was set up at Omsk. This obtained the support of the Allied troops in Siberia and succeeded in restoring some semblance of order throughout Asiatic Russia from Vladivostok to Orenburg. Theodore Roosevelt in his last hours advocated the sending of aid to the heroic Czecho-Slovaks in Siberia and of supporting the *de facto* Government of Siberia in its effort to hold back the tide of Bolshevism advancing from western Russia. The part played by the Czecho-Slovaks appealed keenly to his sympathy and the apparent political detachment of Siberia from European Russia seemed to him to furnish a base for checking Bolshevism. The recognition of the Siberian government will annoy some people because it may look like an encouragement of the reactionary element, but we take the view that the Government of Siberia can be liberalized with more prospect of success than a soviet pandemonium can be rationalized. The party of Admiral Koltchak stands for a national republican form of government, representing all the people, not the proletariat alone; it came into conflict with the social revolutionists led by Nicolai Avksentieff, who was driven from Omsk, but we understand that Avksentieff is now supporting Koltchak, who is also backed by the old Cadet party of constitutional reformers, including such worthy Russians as Professor Paul Miliukoff, Prince George Luov, Madame Breshkovskaya, Messrs. Sergius Sasanoff, the former Minister of Foreign Affairs, Nicolai Tchaikovsky, and Boris Bakhmetieff, the ambassador to the United States. This party stands for order, a constituent assembly, and the popular choice of a form of government through a general election. Those living in Siberia will be grateful for the restoration of order even if the political tint of the present administration is not quite as warm as some of them might wish. For ourselves, we realize that Allied support will regularize the *de facto* Government and give it a chance to bring Siberia out of the gloom of anarchy into the daylight of law. It will have an immediate effect upon the mining industry of a rich, vast, and most interesting country, not only stabilizing the operations already started at Kyshtim, Spassky, Ridder, Tanalyk, and the Lena, for example, but stimulating new enterprises, in which the American mining engineer should play a leading part.

he becomes, for example, the Smith that wrote on the structure of ore deposits in a manner commanding attention; Jones likewise is no longer merely one of a tribe but an individual of distinction when he explains the operations of a flotation process in a lucid and informing manner. When either Smith or Jones travels outside his bailiwick he is greeted by the well-informed as one who wrote something that has been appreciated by the members of the fraternity. One thought more: not much can be accomplished without co-operation; help others and they will help you; play a lone hand and you lose the game. The mining profession is not a mere collection of selfish adventurers or egotistic practitioners, it is a fraternity, a brotherhood of earnest and kindly men, hoping to achieve the worthy purpose of winning friends and of proving effective. Enduring achievement calls for co-operative effort; the engineer's first duty is to be helpful.

Who Will Hold the Sack?

One of the sure signs of a revival of speculative interest in mining is the appearance of prospectuses and circulars inviting the public to become rich suddenly. The wild-cat has issued from his lair and grins cheerfully on a greedy world. A typical invitation is that of the Homestake Gold Mining Company, incorporated in the State of Washington and controlling mining claims in Idaho. By using the name of a famous mine it starts under a flattering illusion, but one provoking suspicion immediately. It "offers the investor the greatest possible opportunity." Another false note, because a prospect is not an 'investment' under any circumstances. The advertisement fails to quote the report of a reputable engineer, therefore its assertion that "there is no question as to the great ultimate value this mining property will attain" is entirely unconvincing. Another interesting 'proposition' is the Ophir Silver Mining Company, the shares of which are offered to us in a circular just to hand from Toronto. We are told that "the vein averages three inches in width, and while there has naturally not been time for assays, my engineer informs me that the ore has every indication of values in excess of five thousand ounces to the ton." This is delightfully ingenuous. We are informed that "Ophir sold up to 11 cents on this news and closed in strong demand." Ophir is a good name, for is it not associated with Solomon and his glory, not to mention the Queen of Sheba; and Cobalt, where this prospect is situated, is a good name in itself; yet we would advise against the purchase of stock in a mine appraised by an engineer unable to find time for a few necessary assays. The circular concludes by asserting that "'the stock will double in value very shortly." It can be doubled by peddling it at twice the price at which it was previously offered, if the supply of shares is controlled by the promoters. That is simple. Next our attention has been called to an offer of treasury stock in the Big Chief Copper Company by means of an advertisement in which it is asserted that this stock "is entitled to be recognized and placed in the column of 'safe investments'." The promoters state that they "recommend it as such," and they proceed to explain that the property "has many exposures of ore carrying copper, gold, and silver, and it looks like a wonderful bonanza mine from the very surface," although as yet the proof of this awaits the "penetration of this ore-shoot" by a lower tunnel. It is acknowledged that other prospects near by are "speculations, pure and simple, as the ore is yet to be found," but "the ore once found generally proves, under efficient management, to be a bonanza." We recognize that bad management may turn 'ore' into 'waste', but no management, however skillful, can put ore where nature has failed to do so. This is one of the fledglings hatched by the boom at Tonopah, the consequence of the big success scored by the Tonopah Divide mine, a genuine bonanza. Already 125 companies have been incorporated to operate in the same locality and thirty of them are actually engaged in exploratory work. Groups of claims with no showing of ore, not even the same rock formation as that enclosing the Divide orebody, are selling for large sums of money. The fact that the Divide shaft was sunk in a hungry-looking breccia in order to reach the extension of the gold ore previously found in the adjacent rhyolite is taken as an evidence of probability in favor of other barren outcrops. The superintendent of the Divide expected to find gold ore in rhyolite and discovered silver ore in breccia, therefore any other similar illogical result seems justifiable to the incubators of wild-cats. It would be natural to argue that as the Divide obviously was the result of accident, assisted by drill and pick, therefore a similarly fortuitous enterprise is more desirable than the 'safe investment'. As a matter of fact, the Divide orebody was found in November 1917, and the proof of an extension of the rich ore has been obtained by eighteen months of honest mining, not reckless conversation. Already the exuberance of a boom has carried share quotations to unjustifiable figures; for instance, the Tonopah Divide is owned by a company capitalized at 1,250,000 shares, which, at the current price of \$11, represents \$13,750,000. To return that amount of money together with 10% per annum for ten years, for example, will require a gross production probably of something like \$40,000,000. The Goldfield Consolidated paid \$29,000,000 in dividends out of a gross output of \$73,000,000. Mines adjoining the Divide, and owned by companies whose shares are quoted at prices that give these prospects a market valuation of two or three million dollars, have only a few thousand tons of ore, plus glittering expectations, to show for the inflation. Of course, the wise ones do not expect to hold the shares for ten years, or even for ten months; they are expecting to find somebody more optimistic on whom they can unload. Perhaps they will; but that is not mining, it is what is vulgarly called the mining 'game', which has the same relation to legitimate mining as the vagaries of the turf have—or had, for they are now extinguished by law—to the breeding of thoroughbred horses. Mining is an industry, not a gamble.

An Engineer's Duty

In a letter received recently from a mining engineer abroad we found this remark: "You are entirely correct in your statement that the writing of an occasional article is a stimulus, and I often regret my neglect of that phase of what should really be considered a part of an engineer's duty." We think it is; an engineer has many duties to perform; this is one of them; it is one of the most useful, and it brings its own reward. The subject is worthy of consideration, particularly in a day and generation when we are realizing with increased bewilderment how little accurate knowledge is obtainable from amid the mass of misinformation that finds its way into print. Our profession, on the whole, is singularly inarticulate. The number of engineers who can write or speak with satisfaction to themselves and their audience is relatively small. The talking is done mostly by the lawyers and the writing by the professors. Yet the engineer is the man that does things, who travels and observes, who comes into personal contact alike with capital and with labor, and who applies himself to the manifold phases of industry with what we call the scientific spirit, namely, a consistent effort to ascertain the truth. The best way to do so is to start by giving away what small part is already acquired. To give is to receive. A humorist has said that the quickest method of obtaining knowledge of a subject is to write a book on it. Many a true word is said in jest. It is certain that the writing of a technical article, for example, is mentally more enriching to the writer than to any of his readers. While engaged in such work he discovers how much he does not know concerning the subject, he proceeds to correct the deficiency, to fill the holes and to bridge the gaps, and, above all, to correlate facts so that their real significance emerges in the form of logical statement. He seizes hold of the amorphous information he has been storing in the lumber-room of his mind and crystallizes it into a shape likely to prove useful to himself and to others. Card-indexes are excellent things in their way, but the habit of writing is a better aid to memory, for it causes the items of knowledge and of experience to be placed in a logical order rendering them memorable. An engineer who puts his ideas and observations into print soon acquires a storehouse of information, which is easily accessible to him, and it is indestructible. We recall the misfortune that befell a Californian family of mining engineers whose notes and data were being collected for their own use, not for publication, because that meant the giving away of trade secrets, as it were. The San Francisco fire turned this accumulation of special information into smoke. They lost it all; if they had put it in print, perhaps for the benefit of others incidentally, they would have derived advantage from the fact that publication involves such multiplication as to escape individual loss by fire or other catastrophe. We recall a mining engineer at Denver who had a hobby for collecting data of technical interest. He accumulated a great mass of valuable information, of which he himself made but little use, and when he died his notes were not in a condition rendering them useful to anybody else, so they also might as well have gone skyward in a pillar of fire or a cloud of smoke. No waste is so pitiful as the waste of experience. Furthermore, of the fund of knowledge that any one of us may possess, all but a small fraction has been given to us. The amount of first-hand knowledge accumulated by any individual is insignificant when compared with that which he has acquired either from his fellows gratuitously or from books at a price relatively negligible. Mean is the spirit of the man that would secrete the little original information he has gained, instead of giving it without reservation in unequal exchange for all that has come to him without cost. Narrow is the mind of him that would withhold information from others, and foolish too, because what he might give is small in comparison with what he might receive in generous reciprocity. Secret technology is an absurdity, in any event, because no process or practice in mine or mill can escape the intelligent curiosity of a man determined to know about it. No extraordinary detective skill is required to ascertain facts the knowledge of which must be shared with numerous operatives, or by a staff the personnel of which is liable to change. Managers notorious for inhospitality in such matters have often proved to be laggards in technical progress, whereas those remarkable for generosity in giving forth information concerning their operations have usually been distinguished for successful work. Engineers willing to help others have been more than recompensed by the friendly assistance offered to them in turn. Apart from such recompense, the engineer finds that his effort to describe his own methods gives him a better understanding of the principles involved and aids him in designing improvements. To write carefully on anything is to clarify one's notions concerning it. Writing becomes a mental stock-taking, a necessary preliminary to intellectual exchange. Two other phases of the subject should appeal to the professional man. The writing of an interesting and useful article—and to be either interesting or useful it must be written carefully and intelligibly, if not attractively—is one of the few ways of achieving honorable prominence. To have ability or experience is not of much avail unless others know that the engineer possesses them. He cannot assert the fact by vulgar advertisement, but he can prove it by occasionally opening the doors of his mind and sharing its valuable contents. Mining, like every profession, is over-crowded; it is well to emerge from the 'and others' for fear of being counted among the 'also rans'. The professional man to be successful in this workaday world must escape from the promiscuity of the mob; he must win individuality and distinction; and he can do it by an occasional writing good enough to give him honorable identity. Next we like to dwell on the pleasant thought that the publication of a signed article makes mental friends; it promotes an acquaintance wider than that of physical contact; it brings a man at once into the intellectual company of thousands. Smith ceases to be one of that numerous family;

DISCUSSION

Colorado Pitchblende Company

The Editor:

Sir—In your editorial of the 29th ult. in discussing the review of the committee appointed by me to consider the McClave report on the Colorado Pitchblende Company's property, you were good enough to give me more credit than possibly I am entitled to. The committee consisted of Messrs. Nye, Malm, and Lowden with Mr. Stahl as secretary, and they are the ones to receive not only your words of endorsement but also the thanks of this community for the care given and time spent upon it. I was out of the city while the review was being formulated and signed it as chairman as a matter of form on my return.

Richard A. Parker.

Denver, April 3.

The Status of Gold

The Editor:

Sir—I have read, with much interest, Mr. John McPherson's letter in your issue of March 22 in reply to Mr. Van Dyck's letter in your issue of February 1, and I find it serves a double purpose because it, also, replies to Mr. Robbins' letter, published in the same issue, that of the 22nd ultimo.

With two or three exceptions, those of your correspondents who have contributed to the discussion on this subject do not seem to comprehend the basic principles of money, presumably because they have not studied political economy sufficiently. There is no royal road to knowledge, but I had hoped that in my article entitled 'What is a Dollar' (M. & S. P., Aug. 3, 1918) I had answered that query with reasonable completeness. Apparently, however, I did not; or else the above-mentioned correspondents did not read it understandingly or did not read it at all. Permit me, therefore, to add the following:

The 'dollar' of the United States of America is 23.22 gr. of fine or pure gold, no more and no less. Similarly the British sovereign or pound sterling is 113.+ gr. of fine or pure gold, no more and no less. Graphically, they may be represented by two cubes respectively 0.16833 in. and 0.2853 in. on each edge. A cube of pure gold of the smaller size will weigh 23.22 gr. and one of the larger size will weigh 113.+ gr.; and 113.+ gr. divided by 23.22 gr. equals 4.8665+, which means that there is 4.8665+ times as much pure gold in a 'sovereign' as there is in a 'dollar'.

Recently, I showed a sketch of the two cubes to a friend, who had given the subject of political economy some thought and study, and, after viewing them for a moment or two he remarked very positively, referring to the smaller cube, "That may represent correctly the size of a piece of gold that will weigh 23.22 gr. but it is not a 'dollar' till the Government stamp is put on it." I replied, with even greater positiveness, that he was wrong, for the simple reason that such stamps or designs are only the Government's assay-certificates, which certify to the fact that the coins, *when freshly minted,* contain the weight of pure gold indicated by the die or stamp. For if, because of abrasion from use, or of mutilation of one kind or another, the original weight of gold is materially diminished and such diminution of contents is discovered, even though the imprint of the stamp is still quite legible, such a coin will not be accepted at its face-value by the Government, by a bank, or even by an individual.

Furthermore, in settlement of balances between nations, the gold in the form of coin or bars or both is melted and assayed and weighed before full credit for their metallic contents is given, because such shipments might contain counterfeits, in addition to coins of light weight due to abrasion or mutilation. My friend admitted the soundness of my argument and confessed that he was wrong in insisting that the Government's stamp gave the 23.22 gr. of gold its value; and I hope any one who may be interested enough to read this will be similarly convinced, for it is a bare statement of fact. To lessen the amount of gold in our gold coins and to then call them by the same names as before would be debasing our money; and 'debasement' is an ugly word; for it simply means dishonesty and fraud, if the new coins are intended to be circulated at the same face-value as the old ones. Let anyone who is interested in this subject read 'A Treatise on the Coins of the Realm', by Lord Liverpool, if he would like to learn about the injury to trade and commerce in earlier times caused by debasing money.

Mr. McPherson's "gold-brass twin coin" is an apt illustration of our *silver* 'dollar', which passes current at its face-value. For, in reality, its currency value is duplex, because it consists of 77.34 cents bullion value, reckoning silver at $1 (23.22 gr. of gold) per oz. and 22.66 cents fiat, or Government credit value. The value of our gold coins is entirely bullion or commodity value, whereas the value of the silver 'dollar' is composite, being made up partly of bullion-value and partly of credit-value; and the value of our paper currency (gold certificates and silver certificates excepted) consists wholly of Government credit.

Much confusion of thought and meaning is occasioned by calling different things by the same name. The silver 'dollar' was made our unit of value when the Mint was established in 1792, and it consisted of 416 gr. of silver of the fineness of 892.4 thousandths. The gold coins of $10, $5, and $2.50 were called eagles, half-eagles, and quarter-eagles respectively. Now, however, all our currency, in common parlance, is a 'dollar' or multiples thereof, whether it consist of gold or silver or paper. In other words, the true meaning of the term 'dollar' is lost sight of because it is commonly used to designate 23.22 gr. of gold, 371.25 gr. of silver, and five different kinds of promises to pay gold.

Finally, and in spite of the foregoing, I would like very much indeed to meet Mr. Robbins and talk with him about the great Hollinger mine, with its multiplicity of veins; and, incidentally, to dine him at a certain club in this city, and, afterward, to select for his perusal a half-dozen books from the 800 or more volumes on economics that may be found in its library. It might take several days, perhaps a week or more, as well as sundry cigars and refreshments to convince him, but I am reasonably sure that, if he will avail himself of the opportunity, it will no longer seem to him "that re-coining at one-half or two-thirds of the present weights of gold coins is a matter which merits a continued discussion.

New York, April 2. W. deL. Benedict.

International Control of Minerals

The Editor:

Sir—In your number of March 15 there appears an article by C. K. Leith on this subject. From the wording of your editorial, in reference to the same, it is to be presumed that you printed this matter rather to promote criticism and discussion than with any idea that it should be read as gospel. I note with surprise, however, that this same article is to be published in 'Mineral Resources' of 1917. In other words, being contributed by a mineral adviser to the War Industries and Shipping Boards, and approved by the U. S. Geological Survey, it is to be held out to the world as an official sample of American thought on the subject.

Mr. Leith says, "The efforts made to promote or hinder international mineral movement by tariffs, bonuses, embargoes, subsidies, transport control, patents, Government management, financial pressure, and other means have been incited mainly by national or imperial self-interest and have thus been to some extent inimical to an internationalization based on the principle of the greatest good to the greatest number."

In an editorial of the same issue as that containing Mr. Leith's article you correctly say: "Even the relinquishment of some part of the sovereignty of the United States is not terrifying, for every decision of international law involves some surrender of national rights; they are conceded just as the individual citizen forgoes some of his private rights for the sake of the community as a whole." Apparently Mr. Leith would surrender national rights of a nature that the individual citizen would not for a moment forego. The individual reserves to himself the right to buy whatever he chooses with his own money so long as he does not monopolize any market. Undoubtedly the statesmen of other nations will require that their countries shall reserve the same kind of freedom. An import tariff is a luxury paid for by the nation itself; it is no one else's business whether that nation buys of other nations or not. I do not believe any foreigner ever objected to the right of the United States to levy lead, zinc, and diamond tariffs, for example. Such a statesman as President Wilson could never have had a thought of binding the United States to any tariff policy, and no such shrewd politician as Senator Knox ever thought the President had such an idea.

If a nation pays a bonus, or a subsidy, or controls its own transport service, or governs its own patents, what business is it of any other nation? the oceans are public highways and not privately owned public utilities. Does not a merchant have a right to give bonuses or discounts to large or particularly desirable purchasers? Does he not have a right to deliver the goods he sells without extra charge or to manufacture his own patented goods? Certainly he does, because he pays the bill with his own money, and everyone else has the same right.

Mr. Leith makes the reservation that his purpose is "to state the problem of international control of minerals, rather than to present an argument for it." He then immediately indicates the nature of the control he advocates by saying, in the same sentence, "such control entails difficulties which are especially burdensome on the United States, and which at present may be insuperable." What minerals are there, produced in the United States, for which the foreign consumer has to pay more than the home consumer? I do not believe that there are normally any export-taxes, embargoes, Government managements, or financial pressures applying to exported raw materials or manufactured goods. Neither can it be said that the United States has any control over the minerals of other countries. Mr. Leith must therefore have in mind some scheme to make the United States a sort of charitable institution, dispensing aid to peoples who do not even ask it, much less think of making war for it.

There is, however, a legitimate field for international regulations concerning minerals, because some nations make the outsider pay, in excessive mineral prices, the accounts that really belong to its own inhabitants. For example, the government of Chile supports itself by making foreign consumers of nitrate pay all the taxes of the country instead of its own people. The South African war was brought about by conditions of a somewhat similar nature, and many costly civil wars have resulted in other parts of the world owing to disputes over the control of a revenue which the people as a whole have no interest in limiting.

The proposals of the League of Free Nations Association of New York, quoted by Mr. Leith, wisely confines itself to monopolies, but fails to include the very important category mentioned above. Neither the evil nor the corrective for these monopolies would seem to have anything in common with the problem stated by Mr. Leith. It is easily understood that the artificial conditions created by the War cannot all be dispensed with in a moment, but the undue or indefinite continuation of such "Government management" is entirely opposed to a basic principle of our civilization, the equality of economic opportunity.

BLAMEY STEVENS.

Guanacevi, Mexico, March 29.

Investing in Oil Stock: A Caution

The Editor:

Sir—During recent months the country has been deluged with a flood of oil promotions, fostered by recent developments in the north-central Texas region. This hysterical fever for speculation which sweeps the country periodically always gives birth to a litter of wild-cats. The last epidemic of the sort centred in the Jerome district in 1916, and a particularly virulent form of the disease it was. Most of the companies organized at that time are now defunct, many without even having started to develop their properties, while a few of the more successfully financed are still spending their remaining funds in an attempt to find another United Verde Extension bonanza. It is a startling proof of the inherent and unthinking optimism of human nature that the very victims of the Jerome awakening are now eager to take a chance on the more distant and less familiar, and consequently more alluring, oilfields of Texas. The oil literature of today shows the same disregard for the truth, the same neglect to mention important facts and places, the same emphasis on valuable discoveries on properties in many cases miles away, as the copper prospectus of three years ago.

There are several important oilfields in north-central Texas, of which Ranger is the best known and most spectacular. It is a mistaken idea that this is an entirely new area, however. The first well at Ranger, the McCleskey, was drilled on October 25, 1917. It was not long before many of the large oil companies and independent producers had acquired leases on the most favorable acreage in an area 150 miles wide by 200 miles long, after careful and exhaustive geological surveys had been made. Six months ago, when the first of the new companies was formed and its stock floated, only areas that for some reason or other had been 'passed up' by the geologists of the big companies could be leased, and those were held at greatly inflated prices. It should be remembered that boring for oil even in a proved field is a decidedly risky undertaking. The reward of success should be, and often is, great enough to compensate for the risk of complete failure; but in buying shares in a new oil venture the prospective reward and the risk of failure should be carefully weighed so that the gambler will at least get 'a run for his money'. This he rarely finds in a company planned and organized as are those now scattering their stock broadcast. Many factors should be considered in this connection, and these factors are usually the very ones that are never mentioned in the average promotion literature. An analysis of the risk involved is far from the thoughts of the oil promoter.

Almost without exception the wells that have 'come in' have had a definite relation to either surface or underground structure. These structural features guide the experienced oil operator in making his locations but are given scant consideration by the wild-cat promoter. Even favorable structure has in many instances failed to yield oil because of local pinching of the oil-sand, a condition that cannot be foreseen. It is evident, then, that even with favorable structure there is a large chance of failure, but without structure almost a certainty of it. To keep the inherent risk-factor as low as possible a careful study of the ground should be made by an oil geologist and his advice followed.

Most of the companies of this nature fail to mention in their literature the large blocks of promotion stock that have been issued for services or leases of doubtful value. Control is usually vested in the few original organizers, who have made only a nominal contribution, while the public at large finances the whole proposition for only a minority interest in the possible profit. A statement of the promotion stock issued as well as of the total authorized amount should be made, so that a prospective purchaser can determine for himself what share in the future profits he will have if oil is found. To protect the stockholders the promotion stock should be placed in escrow until production is secured or the funds are exhausted. The Arizona 'blue sky' law is remiss in many particulars. The mere fact that an organization is permitted to sell stock does not mean that it has the tacit approval of the Corporation Commission; as a matter of fact, most of them are unincorporated and are merely selling shares in an association.

Another important consideration is the heavy expense of prospecting this field, where the most productive sand is in the neighborhood of 3500 ft. deep. Only a company with ample resources should attempt it. A single hole costs between $40,000 and $60,000, and many a hole is lost before reaching its objective. Sufficient funds for at least two or three tests should be available, for by the law of average the first, even if completed, is likely to be dry. It is furthermore necessary for the protection of a lease to be prepared to drill offset-holes to any producing wells on neighboring tracts near the boundary-line. Otherwise neighboring wells will drain oil which rightfully belongs to the lease. It should, therefore, be evident that a strong treasury is essential for successful prospecting.

The question of offsets is also important in connection with the size and shape of the lease. A small or a long narrow tract is undesirable because of the comparatively large number of offset-holes which would have to be drilled to protect it in the event that oil were found. Where holes are so deep and so costly this becomes a vital consideration for the small company.

Most important of all, perhaps, are the men who are behind the organization. The success of the undertaking depends upon them to no small degree, but even with able and trustworthy sponsors a company should lay all the essential facts on the table when it comes to the public for funds. And the public should insist upon getting the facts or refuse to subscribe. Drilling for oil in wild-cat, or undeveloped, territory is a perfectly legitimate speculation. It is only by taking a big risk in the hope of big profit that expansion and development of the natural resources of the country will proceed, but when the risk involved is entirely disproportionate to the possibility of profit the speculation should be avoided. The risk in oil prospecting is very great even when all possible precautions are taken. The chance of success, however, will be far greater if only those amply financed companies, controlled by able and reliable business men, which propose to drill ground recommended by a reputable geologist, are considered. The tracts must not be too small nor too narrow, nor should the company be overburdened with a great load of promotion stock. Those who after reading the lurid promises of the average prospectus 'invest' savings that might otherwise swell the Victory Loan, deserve the fate that is in store for them.

PHILIP D. WILSON.

Warren, Arizona, April 12.

Flotation Litigation

The Editor:

Sir—I have read with great interest the article appearing in your issue of March 22, under the above heading.

Allow me to call your attention to the fact that the trial of the suit referred to between Messrs. Sulman and Picard and myself took place in May 1905 and the judgment was rendered on May 20, 1905. The application for their British patent No. 7803 (corresponding to their United States patent No. 835,120) was filed on April 12, 1905, but I had no information that such application had been filed until after the issue of the patent in January 1906. The application for the United States patent No. 835,120 was filed on May 29, 1905, and the patent was issued on November 6, 1906. Neither the British nor the United States patent was involved in that litigation.

Allow me also to point out that the examination and cross-examination of Dr. Samuel P. Sadtler were had, not in the Hyde case, but in the case of Minerals Separation, Ltd., v. Butte & Superior Mining Company, as appears from the record in the Circuit Court of Appeals for the Ninth Circuit in that case.

In concluding, let me express my appreciation of your having called the attention of the mining world to facts with regard to my patent which were not brought out in the various litigations to which Minerals Separation was a party. As you well point out, the flotation issue will not necessarily be settled by the decision of the Supreme Court in the pending Butte & Superior case, and, as far as my patent is concerned, can only be settled in a litigation in which my patent is directly involved.

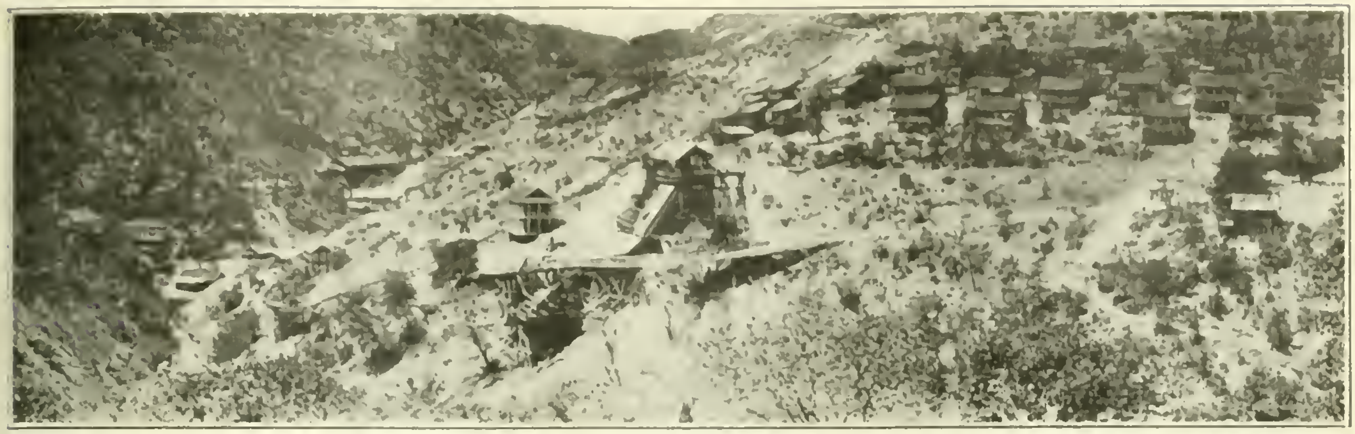
New York, April 7. J. D. WOLF.

Persistence of Ore in Depth at Cripple Creek

Recent correspondence from Cripple Creek, published in the Review of Mining, reports numerous discoveries of rich ore in the district. Some of these have been made by lessees, others by companies, at depths varying from 800 to 2130 ft. The Cresson company has found an extensive shoot at 800 ft., while the Portland is developing two rich veins from the Roosevelt drainage-tunnel at a depth of 2130 ft. The elevation of the Portland's new workings is 8113 ft. above sea-level. On the other hand, the annual report of the Vindicator Consolidated contains the following:

"Early in 1918 development was discontinued on the 20th level, the bottom of the Golden Cycle shaft. On this level a total of 4240 ft. of work has been done, and no ore of a commercial grade exposed. This work has systematically explored the known ore-zones which at this level should possibly produce ore. The vein-systems were found in place and the fracturing was strong and well defined, and with a general physical appearance favorable to ore-deposition. However, the value necessary to make commercial ore was lacking. This level is at a depth of 2150 ft. from the collar of the shaft, and at an elevation of 7920 ft. above sea-level. The productive areas in the property maintained well with depth to an elevation of about 8300 ft. In sinking below this there was a gradual but marked decrease in the production of the areas, the ore-shoots being more broken up, and showing a decrease in the average grade of the ore produced. Extensive work has been done on the 20th level with the view of developing ore below a possible barren zone existing at the elevation of the 19th level, with negative results. There are possibly existing orebodies at a greater depth, but it is the opinion of the operating-staff, from a thorough study of the habits of the existing orebodies, that there will not in this property be sufficient ore opened at a greater depth than that to which exploration work has been carried to warrant the expenses of sinking and exploring. However, this does not mean that exploration should stop, as there is a considerable area on the upper levels of the property that has not been thoroughly prospected, and it is the intention of the management to explore this ground during 1919. Due to the intense labor shortage during the year 1918, this work was impossible."

FINAL FIGURES of the pig-iron output of the United States during 1918 show a total of 39,051,991 tons, compared with 38,621,216 tons in 1917, and 39,434,797 tons in 1916. The production last year was much below capacity.



VILLAGE OF IRON MOUNTAIN

A Metallurgical Journey to Shasta, California

By HERBERT LANG

Shasta county boasts a metal production valued at nearly $200,000,000. Gold, in placers and veins, was the first metal to be discovered. Then came the discovery of silver in the early 'eighties, and now copper, zinc, iron, lead, and chromium have been added to the list, proving the varied resources of this northern Californian mineral-bearing area.

The first metallurgical work in Shasta county was done with a frying-pan. Armed with this instrument, Major Pearson B. Reading, a rancher from Sutter's Fort, near Sacramento, tested the sand of Clear creek and found gold. Later, with the assistance of a few Indians and with the rudest extemporized apparatus, he made himself the possessor of $60,000, working, they say, within a space no greater than a horse-blanket. Others followed him, and still others; and for years Clear creek was the best known and most productive district in northern California. The rich gravel is now worked out; but placer mining is still carried on. The waters of the creek are turbid with the debris of many placers, where the progress of mining methods is marked step by step from the pan to the rocker, the long-tom, the ground-sluice, the hydraulic stream, and finally the floating dredge. At the lower end of Clear creek float the dredges of Gardella; at its headwaters important quartz mines have been exploited successfully. It was at the Washington quartz mine that the first stamp-mill in Shasta was erected. This was of six heads, and seems to have antedated most of the arrastras with which the county was sprinkled. The mill and mine, it is agreeable to relate, produced in all about a million dollars.

Instances of a similar character might be multiplied; the salient fact is that the course of events was like that of other Western regions: as the richer placers became exhausted the poorer gravels began to be worked in a larger way, whereas the quartz mines, which began operations a few years later than the placers, have kept up production ever since, with vicissitudes of depression and excitation. About 1880 the base-metal deposits began to receive attention. Regarded as silver mines pure and simple, they were worked on a small scale for several years, and a few mills were built. Within a comparatively short time the richer silver ores, which, following the general rule, were close to the surface and limited in quantity, were exhausted, and the mills without exception were shut down. This was prior to the fall in silver, which took place in the early 'nineties. A period of depression followed in 1895, while the West was staggering under the blow dealt to silver. Diminishing production marked those years, the annual output, which had been much greater, sinking to $800,000. The mining camps of Shasta assumed a seedy appearance, giving the impress of age to what were relatively new settlements. Old-time camps, such as Piety Hill, Horsetown, Whiskytown, and others, were in decadence. The town of Shasta itself, once the distributing point for the Northern mines, seemed to live only upon the reputation of its former usefulness, one of its principal claims to eminence being the fact that it was the former abode of James Keene, the celebrated financial juggler.

At this time, when the mines had fallen off in their yield and the best blood of the county was leaving, an event took place which was to have the most far-reaching effects upon the fortunes of the county, and in fact upon those of the entire State. This was the sale of the Iron Mountain copper mine to an English company.

The Iron Mountain mine was discovered in 1880, and was acquired by James Sallee, Charles Camden, and their associates. For a time it was regarded as a silver mine, the existence of copper not being suspected. The orebody, as is common in Shasta county, and indeed in many other regions, carried an 'iron hat' of portentous dimensions, easily seen from a distance of miles. Great quantities of this gossan are scattered on the surface and along the canyon of Slick Rock creek. It is a mystery how its content of gold and silver escaped detection for so many years, during which the region was combed by prospectors. But prospecting at that time was an adventure; now it is a business; some day it will become a science. James Sallee, who died, much lamented, about a year ago, was an assayer, and a practical kind of person, whose gifts of industry and enterprise proved valuable to the county in after-days. He it was who took hold of the Bully Hill mines after they had been practically abandoned for years. After some little development, he sold out to Capt. Joseph R. De Lamar. Of this transaction something remains to be said in these notes.

Having at hand no means of reducing the Iron Mountain ores, the new firm proceeded to ship a quantity of selected material to outside smelters, receiving therefor the handsome sum of $100,000. It should be mentioned that certain portions of the orebody had been surface-enriched to a great extent, assays of 100 or even 200 ounces of silver being not uncommon. The rich spots were soon exhausted, however, and the company turned its attention to constructing a mill, in which they were assisted by John O. Earl, an enterprising San Franciscan, who furnished the money for building the plant, the most complete reduction works at that time in northern California. A brief description of this somewhat celebrated silver-mill may not be out of place. The ore to be worked consisted of oxidized material, chiefly limonite, the familiar hydrated oxide of iron, rendered impure by the inclusion of aluminous derivatives of the country-rock, then known as granite, but now called 'alaskite', 'alaskite porphyry', or, more simply, 'quartz-porphyry'. This is the prevailing country-rock of the Shasta copper belt. It analyzes about 70% silica—a fact having a bearing on its employment as flux in the smelting processes subsequently introduced. The copper-sulphide zone had scarcely been reached, nor was its importance recognized for years afterward, as will be shown. Copper was disregarded. Gold existed to a trifling extent in the Iron Mountain ore, as in the other base-metal mines, except the Bully Hill, where it occurred rather abundantly at the very surface. For this reason, attention was given only to the silver. Thus the new mill was a silver-mill, pure and simple, which is not to say that such a mill could not save gold also, for on the Comstock lode, in Nevada, such mills were exclusively employed in treating the gold-silver ore, with reasonable success.

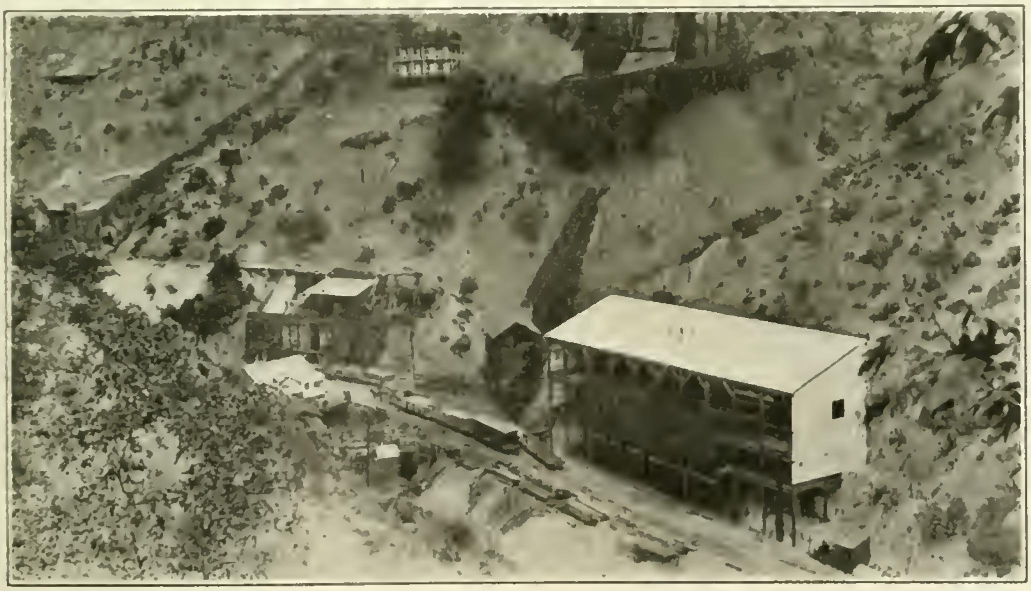
Tests with the mill were said to have shown that 80% of the silver could be saved by simple pan-milling without roasting; and that by roasting the ore before panning, 96% was recovered. This figure is probably an exaggeration, since it was only with exceptionally favorable ore and the greatest skill and care that such result could be attained, and it is certain that the Iron Mountain ores were not exceptional in this respect. Even today in Nevada, such high extraction is uncommon.

The pan process, which is now of little more than historic interest, was carried on in the following way at Iron Mountain:

The ore as it came from the mine was fed to rock-breakers, of which there were two, 7 by 10 in. When broken to egg size, the ore was delivered by gravity to the drying-furnace, a simple cylinder of sheet-iron, placed on a slight incline and fired at the lower end. The dried ore while still hot went next to the stamps, of which there were 20, each weighing 950 lb. and having a total capacity of 40 tons per day, crushing to 40-mesh. The pulverization was dry. Next, the pulp was conveyed to the roasting-furnace, a Brückner cylinder, and was roasted with the addition of 5% of common salt, by which the silver minerals were converted into chloride, susceptible to the attack of mercury. The chloridized pulp was then conveyed to amalgamation pans, of which there were 16, of the combination pattern much used at that day, ground wet with quicksilver, thus forming an amalgam, whose density and mechanical condition admitted of a complete separation from the worthless pulp. After prolonged treatment in pans more water was added and the mixture passed into the settlers, of which there were eight. In these the pulp was stirred gently, permitting the amalgam to settle and to be removed after filtering through canvas, after which it was retorted to separate the silver from the mercury. The silver was melted into bars, commonly of a purity above 95 or even 98%. This is the roasting-amalgamation, or Reese River process. The roasting was sometimes omitted, when the method became essentially that known as the Comstock process, which is effective upon silver ores containing but small quantities of the more difficult compounds, such as the arsenates and antimonates of silver. It was found that the roasting operation increased the cost of treatment from $9 per ton to $17, largely by reason of the expense of fuel and the lessened capacity of the plant. The fuel used was necessarily wood, which cost $4 per cord delivered, and of which a plentiful supply, pine and oak, was available. Eight cords of wood were burnt daily in the furnaces and four cords under the boilers, of which there were two, to provide for the 150-hp. Corliss engine. So much for the Iron Mountain mill, which in its time was regarded as the last word in metallurgical science.

Like most mines the Iron Mountain became poorer with depth, the surface ores of good grade became scarce, and in 1888 the plant was shut-down. This was five years before the disastrous fall in the price of silver. When the mill closed Mr. Earl left the company, relinquishing his rights to Sallee, Camden & Co. They had no trouble in getting rid of him; that gruff personage was said to have observed: "Take your damned old mill, which I have built, and go to hell." They took the mill, but never ran it again. After a period of idleness the property was taken under bond, about 1895, by Hugh McDonnell and Judge Cleary, promoters, who eventually sold it through the agency of Alexander Hill, to British investors, notably Jardine, Matheson & Co., great London merchants connected with the Rio Tinto copper mines in Spain. Then began a new era in Shasta county, during which copper took the place of gold and silver as the main object of exploitation Whatever development the mines of Shasta have undergone is due largely to the initiative of the Mountain Copper Company, as the new organization came to be known. Mr Hill was one of the first to recognize the great possibilities of the property as a copper producer, but not quite the first, since it lies in my recollection that W. Lawrence Austin, the inventor, or at least the improver, of the pyritic method of smelting, who had visited the mine prior to Mr. Hill, had spoken of it as an enormous sulphide body, and had recognized the amenability of its ore to the pyritic process. This was about the year 1891. It is also remembered that the mine was offered for sale to local people, including many Californian capitalists, who were unanimous in 'turning it down', the prevailing impression hereabouts having been that there could be no copper in that part of the State since "our people" had lost money after the copper boom of the 'sixties when, as will be recalled, copper took a decided drop.

IRON MOUNTAIN MINE



LOADING-BUNKERS, IRON MOUNTAIN MINE

It is pleasant to record that although the owners of the mine received but $75,000 for it, out of the $300,000 for which McDonnel and Cleary sold it, they were eminently satisfied, in particular Mr. Camden, who retired on his little fortune to Oakland, where all good miners eventually go, and observed the progress of operations with complacency until the mine under its new ownership began to make large profits. Having felicitated himself at first that he had the better of the British people, his tune changed afterward and he spent his days in complaining that he had been cheated. Mr. Camden, like his partner, Sallee, has gone over the range, while his mine, after an active existence of 20-odd years and the production of nearly $40,000,000, is still alive and profitable. It would be interesting, no doubt, to know who 'absorbed' the difference between the $300,000, which was paid the vendors for the mine, and the $1,000,000 for which it was turned over to the real purchasers, the Mathesons and the other Rio Tinto people who formed what ultimately became the Mountain Copper Co. But this is irrelevant: in fact it is nobody's business, and the question, in view of the present international amity, had better be left alone. It is certain that no American got it.

The methods of the new company differed in some respects from those usually employed in this country, in being more deliberate and more thorough. The opening of the mine is a case in point. Most American engineers would have seen in the great Iron Mountain deposit an opportunity for cheapening extraction by the use of the 'glory-hole' method, whereby timbering with its many drawbacks could have been avoided. The mine suffered from a number of cavings and was on fire for years. Oxidation in such great masses of sulphides is rapid when once the air has access to the interior, and the heat set up frequently proved sufficient to ignite the timbers. The mine was fairly wet, but this fact tended, if anything, to hasten combustion. The fact of rapid oxidation was sufficiently shown in the earlier years by the quality of the water draining from the lower openings, for this effluent water carried copper to such an extent that its recovery was attempted by the old-time method of precipitation on scrap-iron, and a motley array of tubs, tanks, sluices, and vats decorated the hillside for many years. It is likely that the greater part of the cupriferous liquid came from the gossan, the lower portions of which, just above the sulphide orebody, contained, here and there, some copper in the form of chalcanthite. This was moist and porous, facilitating contact with the air, thus forming additional sulphate. The orebody was opened up thoroughly and its limits determined under the direction of Alexander Hill, a most competent manager, who after a distinguished career in various parts of the world, died in 1912. Mr. Hill, at first consulting engineer to the new company, later succeeded Gilbert McM. Ross as manager, and was himself succeeded by Lewis T. Wright, and he by William F. Kett, who now administers the company's affairs. Over all these, and continuously since the inception of the enterprise, has been C. W. Fielding, managing director of the company, now, in consequence of his eminence in financial and, it is said, national, affairs, Sir Charles Fielding, as he was knighted last year.

It has often been remarked that the managers of the Mountain Copper Co. were thorough in their plans and methods. This is shown in the construction of the Iron Mountain railway which connects the mine with the smelter at Keswick and with the outer world. This road is an excellent piece of work, well laid out and well built, though passing through rough country. It was engineered and constructed under the supervision of M. M. O'Shaughnessy, now City Engineer of San Francisco. Its only fault is its steepness, the grade being excessive even for a mining railway, namely 3½%. With its numerous and sharp curves (it is one of the crookedest railroads in the world) it is extremely hard on rolling-stock. The wear and tear upon wheel-flanges and brake-shoes is appalling. Down the descent of 1700 ft. in 10 miles two million tons of ore have rolled and slid to the smelter, the brakes tightly set and everything screeching and groaning. Perhaps it would have been as well to have made the road a little longer and have it come out somewhere else; but smelter-sites are scarce in that part of the country, and Keswick was perhaps the best that could be reached by a road of reasonable length. Perhaps also it would have been as well to have built an aerial tramway. Between the two there was not much choice, as the experience of neighbors has demonstrated. Looking regretfully at the expense and trouble of the steam railroad, Mr. Kett, of the Mountain Copper Co., sighs for a tramway. Others, provided with trams, yearn for railways. Both are good. It is rather a pity that someone with an eye for the future, did not build a real mineral railway, taking in as many of the numerous copper and gold mines as possible, so as to bring their product to some common centre on the main line, thereby solving the problem of transport once for all. The amount of ore thus far handled on rails and wires has already reached seven or eight million tons, and the end is not yet. It has been said that there are, between the Iron Mountain mine on the south and the Golinsky on the north, more than 200 ore exposures that have been mined, and that there are at least 1000 on which locations have been made. None of the mines so far as known have been exhausted, though many are getting poorer. The matter of transport, therefore, continues to be of serious future import.

In order to appreciate the advances that have been made in the metallurgical treatment of local ores, it will be well to consider the character of the minerals composing them. The prevailing ores of Shasta county, excluding the auriferous gravel, may be divided into two classes, namely, gold-bearing quartz and the base-metal sulphides. The former, occurring in typical veins, is in no respect different from the ordinary millstuff of other gold-mining districts. It consists of quartz carrying a small proportion of sulphides—almost exclusively pyrite—with a little gold, free or enclosed in the sulphide mineral. Other sulphides, such as galena, blende, chalcopyrite, mispickel, and pyrrhotite, occur subordinately, as elsewhere. Calcite and dolomite are also found intermixed with the quartz, but generally in small quantity; and fluorite and barite are not unknown. Taken as a whole, the gold-bearing quartz deposits of Shasta are typical of their class, so that no special metallurgy has been needed, old methods sufficing.

Even such exceptional vein-matter as that of the Niagara mine, in the high divide above French gulch, which carried much calcite, and that of the Banghart mine, near Stella, which yielded large lumps of gold from its gouge-like ore, derived not from a quartz vein but a decomposed dike, required no more specialized treatment than ordinary mill-ore. The Banghart, indeed, obtained the major part of its yield from a plain little arrastra.

The stamp-milling practice could scarcely be called good. None of the mills were distinguished for their size, capacity, or excellence of design, and probably few of them did effective work, if one may judge by contemporary accounts or by the evidence of the tailing heaps. Notwithstanding that by the year 1895 the practice of concentrating the tailing had become general elsewhere, the mills of Shasta county were only in part provided with apparatus for this purpose, and it was common even at that date to allow the sand to escape into the stream. In that year the mills of the county contained 290 stamps, but possessed only 35 concentrators, of which the great majority were Frue vanners. Hence there was one machine to eight stamps—a ridiculous disproportion. One mill, the Uncle Sam, with 35 stamps, the largest of all, had 14 Frue vanners, or two to every battery of five stamps—a proportion usual in modern mills.

The lack of capital caused the early operators to resort to many makeshifts, in which respect they do not differ from those of today. Some have an interest, for example, in the miniature plant of a certain little mine at the foot of Iron mountain. Having for a part of the year the use of one of the small periodic streams so common in that region, the owners built a 16-ft. overshot wheel with 34-in. breast, driving a 9-ft. arrastra, with stone drags and pavement. The ore contained a small proportion of auriferous pyrite, necessitating some means of concentrating, so that the tailing was run over, first, a strip of carpet, 25 in. wide by 15 ft. long, and then over 12 ft. of canvas, 5 ft. wide. Thus one ton of concentrate was saved each month. The Little Maud claim, not far away, improved on this modest installation, putting in, instead of the arrastra, a Jones mill, so-called, which was one of the innumerable inventions of that day by which the apparent inconveniences of the stamp-battery were to be obviated. The Jones mill has, like most of its kind, passed into oblivion, and it is only recorded that it resembled the Huntington pulverizer in outward form, but instead of crushing by the pressure of the rollers upon the peripheral die, it had hammers. It had a pan 3.5 ft. diameter and its rate of crushing was 6 tons in 24 hours. Determined not to use any so-called standard methods, copper plates gave way to cone-shaped amalgam-traps.

The arrastra process, introduced to treat the silver-bearing ores of Spanish America, was modified when transplanted to the gold-mining regions of the United States. The arrastra is not a continuously working agent; it works by charges, and when applied to the reduction of gold-quartz is made to combine the functions of pulverizing and amalgamating. After introducing the ore, which is usually first broken by hand to egg-size or less, it is mixed with enough water to form a thick paste when the grinding is completed, in this respect resembling the ordinary pan treatment of silver ores. Unlike the latter, only a small quantity of mercury is added—just enough, in fact, to form an amalgam of the maximum density, which is in the neighborhood of 16, the proportion of gold being nearly 50%. In the silver process a large addition of mercury, sometimes amounting to 50 times the weight of the silver, is made for reasons connected with the specific gravity of the amalgam, which is comparatively low, and also on account of the solubility of the silver amalgam in mercury, which exercises a favorable influence on its separation from the pulp.

After the amalgamation of the metal, which is ascertained by panning, the charges in both cases are thinned by the addition of water, the speed of the grinding parts is increased, and the charge suffered to flow out. But in the arrastra, the amalgam, having subsided to the bottom, collects in the interstices of the rock composing the bed, and remains there to be removed at the clean-up, when the bed must be broken out.

This neat, though slow and laborious, process was much used in Shasta in former days and was highly esteemed. One notable attempt was there made to improve it. Almarin B. Paul, a noted Californian metallurgist, who had distinguished himself in connection with the mines of other localities, notably the Comstock, was a devotee of the arrastra, and made it an important feature of the Calumet mill, not far from Copley. This was a radical departure from ordinary design. Crushing was performed in two of Howland's circular batteries, which, on account of Mr. Paul's advocacy, came to be known as the Paul mill. The peculiarity of the Howland mill lies in the shape of the mortar, which is saucer-shaped instead of straight, the stamps being arranged on the circle. They were simple gravity-stamps, of the usual kind, 8 or 12 in number and of the usual weight. They were lifted by means of a cam fastened to a vertical revolving shaft in the centre, to which motion was communicated by means of gearing. This mill achieved some popularity, but was neither better nor worse than the ordinary type, its principal advantage lying in the less first cost, but particularly in the increased crushing area of the mortar.

Following the stamps came four of Paul's patent blanket concentrators, also a forgotten invention. Finally the pulp passed to four arrastras in which it was reground and again amalgamated. Some success was achieved and the works continued active for several years. In 1892 Mr. Paul added another invention of his to the mill in the form of an Americanized arrastra, of which he set up 24. Later he introduced the cyanide process, but having developed his dry amalgamation process and patented it, he gave his attention later exclusively to this method, which achieved no vogue.

In the effort to avoid stamp-milling a great many other devices for pulverizing and amalgamating came into use. Thus Shasta became, like Boulder county in Colorado, a refuge for the inventive process-man. Among the legion of 'improved' machines, the cannon-ball mill for a time held an exalted place. This mill, which became the progenitor of many better forms, proved faulty in several particulars. The balls followed each other around a circular raceway, which they were supposed to fit, grinding the ore beneath them. While they kept their size and shape they performed well; but as they wore away the useful effect diminished. When the balls became small the raceway became larger and their surfaces ceased to connect, so that the capacity of the mill decreased. Many of these machines, so beautiful in principle, were erected in California in early days, but it was rare that one ran longer than a month or two. It was only after men had learned to turn the balls loose in the ore and let them take their own path that success was achieved. To do this it was necessary to tip up the mill so that its vertical driving axis became horizontal, and to increase the number and diminish the size of the balls.

The New Price Revolution

By IRVING FISHER

At the present time there is a marked halt in production. Industry is slowing down. Unemployment of labor increases. Some industrial concerns are failing to earn profits, and others are suffering the dissipation of their accrued profits, because, even by shutting their plants down, they cannot save certain of their expenses or any of their fixed charges. The Government's revenues, dependent as they are upon the national income, may fall short at the very time we need them most. In brief, we are threatened with a widespread business depression and from peculiar causes, for the unsound conditions usually preceding a widespread business depression are absent.

The main reason why business is not going ahead better is that most people expect prices to drop. The merchant is selling, but not buying. The manufacturer holds up the purchase of his raw materials. People quote the disparity between present prices and those prevailing "before the War," and decide they will not buy much until present prices get down to "normal." This general conviction that prices are sure to drop is putting a brake upon the entire machinery of production and distribution. Readjustment waits because we keep on waiting for it. We have waited in vain for over three months. It is interesting to observe that many manufacturers think that prices must come down, including the price of labor; but they are ready to demonstrate to you that their own prices cannot come down, nor can they pay lower wages. Almost everything they buy somehow costs twice as much as before the War, and their labor is twice as dear. They cannot pay their labor less if labor is to meet the increased cost of living. Now, as a matter of fact, when we investigate almost any individual one of the so-called high prices for industrial products we are likely to find that individually it is not high; that is, it is not high relatively to the rest. Our quarrel is with the general level of prices.

Variations in the general price level may be compared to the tides of the sea, while individual prices may be compared to waves. Individual prices may vary from this general level of prices for specific reasons peculiar to individual industries, just as the height and depth of waves vary from the general level established by the tide. The causes controlling the general price-levels are as distinct from those controlling individual prices as the causes controlling the tides are distinct from those controlling individual waves.

All prices have risen, but some have risen more, some less, than the average for particular reasons affecting each industry. In some cases an improved organization of both employers and employees has enabled them to combine against the public and take full advantage of the price-advance. The War brought about an abnormal demand for certain products like copper and steel, and they advanced faster than the average. The abnormal demand having disappeared, these prices are being adjusted downward. Wheat is a case where demand increased and at the same time certain of the usual sources of supply—Russia, Australia, and Argentina—disappeared, with a resultant abnormal price increase. The closed sources of supply have opened again, and wheat prices in the world market have dropped. In some cases, as in many of the industries making building materials, the War meant a great slackening in demand, an enforced curtailment in use by Government order. In such instances we are likely to see an upward swing in prices as the suppressed demand again makes itself felt. To-day we are witnessing throughout the country such price readjustments, up and down, but the general price-level has shown little sign of falling, as is evidenced by price index-numbers. It is apparent to every thoughtful observer that some great force has affected all prices, creating a new standard to which they are all conforming.

The fundamental practical question confronting business men is whether the general level of prices is going to fall. In my opinion, it is not going to fall much, if at all. We are on a *permanently* higher price-level, and the sooner the business-men of the country take this view and adjust themselves to it the sooner will they save themselves and the Nation from the misfortune that will come if we persist in our present false hope.

The general level of prices is dependent upon the volume and rapidity of turnover of the circulating medium in relation to the business to be transacted thereby. If the number of dollars circulated by cash and by check doubles while the number of goods and services exchanged thereby remains constant, prices will about double.

The great price changes in history have come about in just this manner. The 'price revolution' of the 16th century came upon Europe as a result of the great influx of gold and silver from the mines of the New World. Europe was flooded with new money. More counters were used than before in effecting exchanges and prices became 'high'. People talked then of *temporary* 'inflation', just as they talk of it now. But it was not temporary; it was a new price-level.

A similar increase in prices all over the world occurred between 1896 and 1914, following the discovery of the rich goldfields of South Africa, Cripple Creek, and Alaska, the invention of the cyanide process in mining, and the vast extension of the use of bank-credit.

Circulating credit, that is, bank deposits subject to check and bank-notes, is a multiple of the banking reserve behind these deposits and notes; and the essence of this reserve is gold. Our present monetary system is an inverted pyramid, gold being the small base and bank-notes and deposits being the large superstructure. The superstructure grows even faster than the base. The deposits are the important elements. They are transferred by check from one individual to another; that is, the circulation of checks is really the circulation of deposits.

Thus any increase in the country's gold-supply has a multiplied effect. The possible extent of that effect is dependent upon (1) the amount of gold available, and (2) the gold-reserve requirements, determining the volume of credit that can be put into circulation based upon the gold. Over a billion dollars in gold has come into this country from abroad since 1914, and a large amount has disappeared from domestic circulation. The gold from both these sources has found its way into the United States Treasury and into bank reserves. On June 30, 1918, the portion of the *gold* reserve of the Federal Reserve banking system, which supported National Bank deposits and Federal Reserve notes, was more than three times as large as the gold reserves under the old national banking system on June 30, 1914—$1,786,000,000, compared to $592,000,000. During the same period credit instruments (demand deposits and notes) increased about twofold—from $6,100,000,000 to $11,700,000,000. This increase of credit instruments is typical of the banking situation for the country as a whole and largely explains the present high level of prices. The increase of gold has been so great, however, that the base has grown faster than the superstructure—which is contrary to the normal tendency. The ratio of gold to credit has risen from 9.6% to 15.3%. The legal reserve requirements of the present system are such that for 1918 there is an excess of gold above these requirements of more than $700,000,000. The reserve required by law to support the $11,700,000,000 of credit instruments of 1918 is $1,070,000,000. The $700,000,000 of free gold could support an additional superstructure 70% as large as the existing one, which indicates that for the banking of the country as a whole a potential future expansion of 50% is a conservative estimate.

Many people, referring to this inflation in the circulating medium, and assuming that it is temporary, are waiting for this inflation to subside. When we speak of *inflation* we mean more circulating medium than is needed to transact the business of the country on a given price-level. But what price-level? Some people mean the price-level of 1913-'14. Our currency is certainly inflated in terms of the prices of that period, just as the currency in 1914 was inflated with respect to the prices of 1896, but our currency is not inflated at the present time relative to the new level of prices in the world which the War has brought. The country's volume of money will have to be judged in terms of this new price-level, not in terms of a price-level that is past. To speak of the present 'inflation' as temporary is to assume the very thing about which we are contending—to assume that the normal prices are those of 1914.

Let us examine the factors upon which any future price movements must depend:

1. Gold will not return to circulation.—No great effect in the direction of falling prices can be expected from any return of gold and other lawful money into daily circulation. Such a reversion would be contrary to monetary experience everywhere. When people have learned to leave their gold and silver in the banks and use paper-money and checks instead they find the additional convenience so great that they will never fully return to the old practice.

2. No great outflow of gold through international trade.—It should be noted that many of the former reasons for a flow of gold from America abroad have disappeared. We used to owe Europe a huge balance of interest payments upon American securities she held. The situation is reversed today. Moreover, Europe must pay us money for the materials we will send her for reconstruction, or at least pay us interest on credit we will extend her. Thus our exports will probably exceed our imports during the reconstruction period. We used to pay ocean-freight money to foreign carriers; today the American merchant marine will keep in American hands tens of millions of dollars of ocean-freight money. The huge volume of American tourist-travel abroad, for whose expense we had to settle, has stopped and can not resume for a year at least. For all these reasons the lines are laid for a movement of gold from Europe here rather than a movement of gold from America to Europe.

"Yes, but," people say, "wait until trade is resumed between the United States and Europe, then surely 'low-priced European goods' will flow over here in such enormous volume that they will liquidate all annual obligations to us in goods." Ultimately Europe must pay her obligations to us in goods, but it will take many years. Meanwhile she needs our tools, machinery, and raw materials for immediate reconstruction.

At the present time European goods are not 'low priced' (however little the money-wages of European labor will buy). Prices in Europe since the War began have risen more than they have in the United States. The price-rise has been less the farther from the seat of hostilities. It was least in Australia and New Zealand. It was next least in the United States, Canada, and Japan. Then came neutral Europe; then our present allies; and finally Germany and Russia. Gold tends usually to flow from high-priced countries to low-priced countries, so that until 'inflated' European prices fall gold is not likely to flow thither. Prices are no more likely to fall there than here, and for the same reasons, which will be explained below.

3. Reduction of outstanding credit.—The chief dependence of those who predict lower prices is on a reduction of the superstructure of credit resting upon our gold rather than on any reduction in the volume of this gold itself. They look for a contraction of bank-credit.

a reduction in the volume of deposits subject to check. which circulate throughout the country.

But the main cause for the present extension of bank-credit is the Liberty Loan, and there is soon to be another. Subscribers for the new loan will not pay for their bonds in full any more than they did in the previous cases, but rather less. Many of them will deposit the bonds with the banks as security for loans to be re-paid later. The effect on our circulating medium will be the same as if the Government were to impose a levy of $6,000,000,000 of credits upon the Federal Reserve banks, and then order them to apportion these credits out among the banks of the country. This process will certainly lead to an expansion of credits. The former issues of Liberty bonds are still carried by the banks to a considerable extent. It may be contended that the bank-credit expansion represented by the new Victory notes has already occurred in the form of Treasury certificates, which are merely to be funded by the Victory notes. The Victory note issued thus represents only a shifting of the obligation to pay credits advanced to the Government, a shifting from the shoulders of the banks to the shoulders of the Victory-note buyers. The volume of outstanding bank-credit remains the same. To a certain degree this contention is true. But a portion of the April Victory-note issue will go to pay future expenditures, not accrued expenditures. Then as soon as the Government needs additional money, it will issue new Treasury certificates, resulting in new extension of bank-credit. Moreover, there is little doubt that there will be at least one more Government bond-issue during the reconstruction period, and this will tend to further increase our present credit structure. [The Secretary of the Treasury says that there will be no more issues.—EDITOR.]

The banks must lend credit and create deposits to meet the expenditures not only of our own Government, but of foreign governments as well. The same thing results even if these governments are served directly by private investors here instead of through the United States Treasury. These investors pay for foreign Government bonds as they do for our Liberty bonds—on the installment plan—paying a small part down and borrowing the rest from the bank. This increased purchasing power will be mostly spent in this country for supplies to be sent abroad for rehabilitation. This continuance of vast loan-issues, connected with war and reconstruction throughout the world, is a factor which will maintain the high price-level temporarily, which means many months.

It is also worth keeping in mind that Liberty bonds and other Government securities held here do not wholly cease being a source of credit expansion when the individual subscribers have completed their payments on the bonds and really own them. These new bonds are unrivaled security for further borrowings from banks for commercial purposes, and they will continue to be so until the Government which issues them redeems them.

The availability of the vast issues of war-bonds as bases for future credit expansion, coupled with the fact that our banking system has still many unused reefs, sure to be taken out later, when business wishes to spread more sail, is the chief reason why prices will keep up permanently, that is, for many years.

Between the period of temporary and the period of permanent effects, there may be a slight dip in the price-level, say, a year from now. If so, it is the more incumbent upon business to proceed now; for it cannot wait a year. During the War the flotation of stocks and bonds of commercial concerns has been greatly diminished. During the period upon which we are now entering, the issue of such securities will increase greatly.

Against any considerable reduction in bank-credit and hence in the general level of prices, we shall find the whole business community in arms. Falling prices mean hard times for the individual and for the nation, and every one resists the tendency. At the end of the Civil War the Treasury started to reduce the quantity of greenbacks. A start had hardly been made, however, before the business depression of 1866 and 1867 caused Congress to forbid by law any further reduction. Should the Federal Reserve banks attempt, by raising their discount-rate or otherwise, to reduce the volume of bank-credit outstanding, they will meet with the same sort of opposition. Moreover, the hostile attitude of labor toward the lowering of wages will deter legislators and bankers from any organized policy of contraction.

Looking into the still more remote future, there will be in Europe, particularly on the Continent, a vast increase in deposit-banking. The need of the governments there for funds during war-times hastened the introduction of deposit-banking. Money went out of circulation into bank-vaults, and there became the basis for circulating credits. This means a new habit which will lead to a great currency expansion. Far-away countries, like India and China, are also learning to use deposit-banking. It is as if a new source of gold-supply had been discovered. What has been discovered is a new way of using the gold-supply. The world, during the course of the War, has thus started, or has hastened, an equivalent of the price revolution of the 16th century.

Business-men should face the facts. To talk reverently of 1913-'14 prices is to speak a dead language today. The buyers of the country, since the Armistice, have made an unexampled attack upon prices through their waiting attitude, and yet price recessions have been insignificant. The reason is that we are on a new high-price level, which will be found a stubborn reality. Business men are going to find out that the clever man is not the man who waits, but the one who finds out the new price-facts and acts accordingly.

ARRANGEMENTS have been made to continue the investigations on the manufacture of graphite crucibles at the U. S. Bureau of Mines' experiment station at Columbus, Ohio, with particular reference to quality of crucibles that may be made of domestic graphite. Statistics of production and stocks of graphite are no longer collected monthly by the U. S. Geological Survey.—F. B. Hyder in March report of the Bureau of Mines.

The German Metal Octopus—I

ISSUED BY THE ALIEN PROPERTY CUSTODIAN

Introduction. To appreciate what has been accomplished in ridding the metal industry of the United States of the influences of the so-called German metal octopus, it is necessary to briefly sketch the growth of the German metal concerns on their native soil, and then to point out how these gradually invaded foreign markets and to what extent the American metal markets came under their domination. At the outset, however, it must be pointed out that however much justification there is for the assertion that the German metal combine controlled the metal markets of Europe and Australia—especially in zinc and lead—it is not the fact that they controlled the metal market of the United States. Their influence here was potent, no doubt, and it was growing, but it was far from sufficient to control either the production or the price of metals in the United States. The octopus was spreading his tentacles across the Atlantic, but he had not yet assumed the 'octopian' proportions.

The Alien Property Custodian has taken over the German-owned metal concerns in the United States, and, by disbanding some and Americanizing others, it is believed that the German influences in our metal market have been completely eliminated.

Growth of the German Metal Trade. Germany has never been a great producer of metals. Her production of copper is but 3%* of the world's output, against about 60% produced by the United States. Her production of refined zinc is about 28% of the world's output, and of lead she produces 16% of the world's total production. Yet unquestionably Germany has for years controlled the zinc and lead metal markets of Europe and of the rest of the world except the United States. What is the secret of her power? It is not alone that she is a large consumer of metal. For though she consumes annually about 500,000,000 pounds of copper more than she produces, she consumes only 23% of the world's zinc against her own production of 28% of the world's output; and of lead she consumes only 20% of the world's output against her own production of about 16%. Yet she completely controls the zinc and lead markets of the world. The secret of her power lies in the fact that her great metal firms act in concert in the purchase of zinc and lead ores, co-operate in the control of smelters and refineries, and, by the free use of unlimited credit extended to them by the German banks, who themselves participate in these industrial enterprises, they are enabled to buy and sell huge quantities of metals, thereby influencing the market prices.

The German Metal Triumvirate. There are but three great international metal concerns in Germany—the Metallgesellschaft of Frankfurt, Aron Hirsch & Sohn of Halberstadt, and Beer, Sondheimer & Co. of Frankfurt. These giant organizations, whose operations now circle the globe, are of comparatively recent development and are the growth of very small and humble beginnings.

Around the year 1800 there were in Germany three small concerns or individuals devoting themselves to the metal business, namely, Jacob Raviné, Berlin; Philip Abram Cohn, Frankfurt; Aron Hirsch, Halberstadt. They traded in the products of the country—lead produced in the Hartz mountains or in Saxony or Silesia, copper produced by the Mansfield works and other small concerns, and they also brought in some copper from Sweden.

In the 19th century the three concerns developed on somewhat different lines: Raviné drifted more into the iron business, Cohn developed into a large metal merchant, and Hirsch developed into a combination of industrial manufacturer and metal merchant.

(1) *The Metallgesellschaft* is the largest of these concerns and is by far the most powerful metal concern in the world. It is a stock corporation with a capital of 18,000,000 marks. It is the outgrowth of the metal business founded by Philip Abram Cohn early in the 19th or late in the 18th century. In the early 'sixties of the last century, Henry Merton, whose real name was Moses and who was related to Philip Abram Cohn, founded a metal firm in London which later became the powerful house of Henry R. Merton & Co. The Metallgesellschaft and the Merton firm worked hand-in-hand for the advancement of German domination of the metal markets of the world.

(2) *Aron Hirsch & Sohn*, a co-partnership, is the business founded by Aron Hirsch and it has always been kept in the Hirsch family. This house has not confined itself strictly to metal trading but has also engaged in metal manufacturing. It has interests all over the world.

(3) *Beer, Sondheimer & Co.*, a co-partnership, was founded in the latter part of the 'seventies by Messrs. Beer and Sondheimer, two salesmen of the Metallgesellschaft, who broke away from the Metallgesellschaft and with the assistance of the Mitteldeutsche Credit Bank started in business for themselves under the name of Beer, Sondheimer & Co. This firm has confined its activities principally to the zinc-smelting business.

The Federal Trade Commission in its Report on Co-operation in American Export Trade issued in 1916 has included a very excellent chart showing the inter-relations between the German metal-houses. This has been used as a basis for the charts hereto annexed which havbeen brought to date according to the latest information available, and which show the ramifications of the German metal combine. We find in their control not only German metal and chemical companies, but also French, Belgian, English, Australian, American, Swiss, Austrian, Italian, Spanish, and Mexican. In addition, they control syndicates for the exploration of mines in South America, Hungary, Russia, and the African continent. In this vast combine we find charted 245 separate companies whose interests lie in almost every part of the globe and who produce every known form of mineral.

---

*All figures herein regarding Germany are for 1913.

The Zinc Syndicates. At the outbreak of the European war the zinc industry of the whole world, save only the United States (as to which comment will be made separately), was completely in the control of the German metal triumvirate—the Metallgesellschaft, Aron Hirsch & Sohn, and Beer, Sondheimer & Co. The control of the purchase of ores, principally Australian ores, was exercised by means of joint accounts among the three German firms, while the control of the smelters and the zinc spelter which they produced was exercised in Germany by the German Zinc Syndicate, and in the other European countries by an International Zinc Syndicate. But the Metallgesellschaft—and its English offshoot, Henry R. Merton & Co.—Aron Hirsch & Sohn, and Beer, Sondheimer & Co. were in absolute control of these syndicates.

(a) *The Australian zinc-ore purchasing combine.* When Australia, during the 'nineties of the last century, came to the fore as a large metal-producing country, principally zinc ore, the German metal triumvirate— the Metallgesellschaft, Aron Hirsch & Sohn, and Beer, Sondheimer & Co.—took hold of the situation and became the dominating influence in the purchase of the Australian zinc ores. This took the form not of a syndicate but of an arrangement for joint accounts, resulting in the elimination of nearly all competition both in the purchase of raw material and in the allocation of the ore among the smelters on the European continent. It is interesting to note the development of this combine:

The Broken Hill mines in Australia were prolific producers of zinc ore. The annual production was about 477,000 tons. The ore was refractory, and there was great difficulty in disposing of the huge production. England, apparently, was not in a position to handle the product, and a situation developed more or less similar to the situation which arose in the United States in the 'eighties when England, through her inability or unwillingness to treat the copper product coming from America, stimulated the erection of large smelting and refining plants in the United States. The three German metal concerns immediately invaded the field and sought to find a market for this tremendous output. Each of them opened an agency of its own in Australia. The Metallgesellschaft created for this purpose the Australian Metal Co. Aron Hirsch & Sohn formed a connection with Francis H. Snow of Adelaide. Beer, Sondheimer & Co. engaged the shipping firm of Elder Smith & Co. as their agents. At first these German firms were in keen competition with one another in the Australian field, and there were also in the field several English firms, as well as the great Belgian zinc smelting concern, Société Vielle Montagne. Competition was very keen and profits small. Production was increasing all the time. During the Boer war and the depression incidental to it the metal concerns suffered severely under their contracts with Australians and as a result of the losses which they suffered during that period they came to the conclusion that, being the largest buyers of products coming from Australia, a way should be found to eliminate the competition both in the purchase of raw material and its disposal to the various smelters on the European continent. About the year 1902 joint accounts were arranged—first between the Metallgesellschaft and Aron Hirsch & Sohn in which later on Beer, Sondheimer & Co. were included and a working arrangement was reached with the Société Vielle Montagne. These arrangements were nothing but loose joint-account arrangements changeable and changed from time to time, but, in effect, they resulted in a dominating influence as far as the purchaser of zinc ore was concerned, which continued to be exercised by the German metal triumvirate until the outbreak of the European war.

Having acquired what amounted to practically a monopoly of zinc ore, the German metal triumvirate next sought to obtain control of the smelters where the ore was treated and of the spelter, which is the finished product. And here they sought not only to control the output of the metal but also to fix the prices. They established zinc smelters in Germany, Belgium, France, Russia, Poland, and Austria, and they even acquired interests in British zinc smelters. Aron Hirsch & Sohn, for instance, practically owned a zinc smelter at Swansea Vale, in Wales. They succeeded completely in Germany, where they established the German Zinc Syndicate, which controlled the output of zinc in Germany and fixed the prices therefor. They also succeeded in establishing an international zinc syndicate, but through that they regulated only the output outside of Germany and not the prices.

(b) *The German Zinc Syndicate (Zinkhüttenverband).* This was organized in 1909 with a capital of 2,000,000 marks. The organizers were the same old triumvirate, the Metallgesellschaft, Aron Hirsch & Sohn, and Beer, Sondheimer & Co. All the large zinc concerns of Germany entered the syndicate, with the single exception of the firm of Giesche's Erben; but even this concern agreed to sell only at prices fixed by the syndicate. The triumvirate was appointed the exclusive selling agent of the syndicate and through a subsidiary of the syndicate, the Kolner Zinkhüttenverband, the syndicate regulated the prices of zinc in Germany. The syndicate is said to be absolute in its control of the German zinc output and in price-fixing. Through the German Zinc Syndicate the Germans have controlled one-half the zinc output and about one-third the world's output.

(c) *The International Zinc Syndicate.* With such a large control of the world's zinc output the German Zinc Syndicate became a menace to the English, French, and

THIS CHART APPEARED IN A REPORT OF THE FEDERAL TRADE COMMISSION DATED JUNE 30, 1916

Belgian smelters. For their own protection, therefore, the English works formed a syndicate of their own, while the Belgian and French works formed a separate syndicate. The most important Belgian zinc concern, the Société Vielle Montagne, which had extensive works all over the world, had, however, entered into a working agreement with the German zinc syndicate, so that the German Zinc Syndicate's preponderance over all the others were so great that they were forced to join the Germans in the formation of the International Zinc Syndicate, which was formed in 1911. In the preamble to the contract creating the International Zinc Syndicate, the purpose of the syndicate is stated as follows:

> "The undersigned German, Austrian, Belgian, French, Dutch, and English zinc smelters have agreed to combine for the purpose of curtailing the actual total production, if proof is available that consumption does not absorb the production."

The duration of this syndicate is fixed for five years beginning January 1, 1911. There are three groups, the first group representing the German zinc smelters, Belgian and French smelters controlled by German concerns; the second group represents Belgian zinc smelters owned by Belgians; the third group English smelters regardless of ownership. The arrangement states:

> "A curtailment of production is to be effected whenever the stocks held by the various zinc smelters at the end of a quarter exceeds 50,000 tons, provided, however, that if the price of spelter in London should be £23 or more no curtailment of production is to take place."

Changes in the price for the metal were agreed upon from time to time at meetings held by the zinc smelters, according to the necessities of the market. For the purpose of distributing the product of the smelters and for the purpose of avoiding competition, the sale of the metal was placed in the hands of the three German metal concerns—the Metallgesellschaft, Aron Hirsch & Sohn, and Beer, Sondheimer & Co. and their branches. Not all the zinc smelters were bound; some of the more important ones retained their selling organizations, but they were bound to the price agreement as laid down by the zinc syndicate.

This syndicate absolutely controlled the world's output of spelter (except the United States), and though theoretically all the syndicate members except the German works were free to fix their own prices, in practice the German metal triumvirate fixed the prices, since the International Zinc Syndicate prices and those of the German Zinc Syndicate were always the same.

The Lead Syndicate. At the outbreak of the European war the lead output of the world was likewise centred in the hands of the Germans. The Metallgesellschaft had the exclusive sales agency of what was known as the International Lead Convention, which was formed in 1909 and continued thereafter for a number of years. It embraced the principal Australian lead-producers, as well as most of the German, and most of the Spanish and Belgian lead mines. At least two American firms, to wit, the American Smelting & Refining Co. and the American Metal Co., as far as their production of lead from ores imported in bond is concerned, and some of the Mexican mines, were likewise members of the syndicate which regulated output and fixed prices.

Copper. In copper the Germans were never able to gain control of production, but they had a marked influence on the market price of the metal. Their inability to control the production was due to the fact that the mining industry of the United States, which produces more than 60% of the world's total output of copper, could not be brought under German domination. The large American producers have maintained their own agencies abroad and have through those agencies dealt directly with the foreign consumers. Important American producing concerns like Anaconda had branch-offices of their own in London and later on in Berlin and Paris. The American Smelting & Refining Co. had the same organization. The Calumet & Hecla Co. was represented at London and Paris, and at Bonn, in Germany. Phelps, Dodge & Co. were represented in London, Paris, and Frankfort on the Main. All these important American producers practically prohibited the sale of copper except to consumers, through their foreign branches. Nevertheless, the European metal merchants did buy copper from some of the large producing companies in America, but these purchases were negotiated in nearly every instance in New York between the seller and the respective agent of the European purchaser.

Outside the United States, and especially in Australia, the Germans did largely control the copper output. The Metallgesellschaft through its Australian Metal Co. at one time exercised a decided influence in the copper business of Australia. Aron Hirsch & Sohn, however, later became the most important copper interest in Australia. This firm had control, through refining and purchasing contracts, of the copper production of the three largest copper producers in Australia, to wit, the Mount Morgan Gold Mining Co., the Wallaroo & Moonta Mining & Smelting Co., and the Mount Lyell M. & R. Co., having a combined total output of about 15,000 tons as against 45,000 tons, which was Australia's total annual output of copper.

But though Germany has never controlled the output of the world's copper, she has exercised a powerful influence over the price of the metal. This was due to two causes: (1) Because Germany was a large consumer; (2) on account of the activities of the German metal triumvirate.

In 1913 the world's total production of copper was about 993,000 tons. Germany produced only about 30,000 tons, or a little over 3%. The world's consumption of copper in 1913 was about 1,000,000 tons and Germany alone consumed 256,500 tons, or more than 25% of the world's total consumption. Germany imported most of her copper from the United States. In 1913 she took from the United States about 200,000 tons. It is but natural that the huge buying power of German consumers would wield a marked influence on the price of copper. There is no direct proof, however, to show that the German consumers buy as a unit nor that the German metal triumvirate act in concert in making purchases of copper. In fact, Beer, Sondheimer & Co. play an unimportant part in the metal trade as far as copper is concerned. The most powerful group in the copper markets of the world, outside the large American producers, was the Merton-Metallgesellschaft-American Metal Co. group. Next to them the Hirsch-Vogelstein group. There is no evidence that these two groups co-operated in their copper business. Statistics show that the American Metal Co. controls by purchasing contracts and selling agreements about 250,000,000 lb. of American copper; Vogelstein controls in a similar way about 150,000,000 lb. of American copper. In addition to this the Hirsch group controls about 30,000,000 lb. of Australian copper, while the Merton-Metallgesellschaft group controls probably a similar quantity of copper of various origin. It might be assumed, therefore, that the two groups control together about 460,000,000 lb. of copper, or approximately 23% of the world's market. This in itself would not have given them the power which they exercised in the market. The underlying reason for that power must, therefore, be found elsewhere.

It is believed that the underlying reasons will be found primarily in the ability of the German metal concerns, by the use of their unlimited credits, to finance large purchases of copper over long periods of time, including periods of depression, and secondarily in their splendid organizations and ability to operate on metal exchanges abroad, thus taking immediate advantage of fluctuations which in a large measure they themselves create.

Since the days when Lewisohn Bros., in New York, were active trade manipulators and selling agents of copper—from 1890 to 1899—there was no important copper house in the world outside the two above-mentioned German firms. These firms took advantage of the psychology of the situation as well as of the facilities which the European markets offered to them and the high credit which was at their disposal. They operated on the metal exchanges of London, Hamburg, Berlin, and Havre, and, anticipating market movements, they either bought or sold on these exchanges, thereby creating sentiment, and, through a well-developed chain of agencies which they had established in all of the principal consuming centres of the world, they had a decisive influence on the policy of consumers. In America there was no open trading in copper and the business was done absolutely between selling agencies and consumers. In Europe the metal dealers, and there were many in addition to the three big German firms, acted, so to say, as a buffer between the producing interests and the consuming interests and helped to tide over changes in the markets so that the changes were much more gradual than in the United States. American consumers, and, as a matter of fact, all consumers, prefer to buy on a rising market and hesitate to buy in a falling market. When markets were lowest, when producers were tired out by a long period of business inactivity, when stocks were accumulating in the hands of producers, these large German metal firms entered into the market and bought large tonnages of copper at low prices. The purchases were often in quantities of 10,000 and 25,000 tons at a time. The effect of these purchases was, in the first place, to relieve the producer of his accumulating stock of copper and thereby remove pressure from the market; in the second place, after they had purchased these large quantities of copper, then by encouraging the buyers, by manipulating the metal-exchange markets, and by withholding offers from the market, they created an improved market sentiment and started the market on a boom of which they in turn took advantage by selling at higher prices quantities of copper that they had accumulated at low prices.

As pointed out recently by a prominent American producer, the manipulation of markets for futures and the power to buy huge quantities of copper at low prices have given to foreign consumers the advantage of having been able to buy American copper on an average of one cent less per pound than the domestic consumers had to pay for it.

While the German metal-houses largely speculate in futures of copper, the theory of the large American producers has been that speculation should be eliminated. The results of such a policy are rigid conditions and long periods of inactivity following periods of advances. It stands to reason that at the termination of a purchasing movement when consumers had bought at advancing prices and an increased impetus for forward delivery had run its course, a market had to be reached when purchases ceased and when consumers sat down to wait for weeks and months until they should resume purchases. These were the periods when the Germans came into the market and made purchases in large quantities.

Thus we see that Germany through her three large metal concerns absolutely controlled the zinc and lead markets of the world and exercised a powerful influence over the price of copper to the extent of being able to buy her copper from America at a lower price than the domestic American consumer had to pay for it. But of what significance is all this to the United States since the German and international zinc syndicates did not control the American output of zinc and only partially that of lead, and since they could not control our huge production of copper? This brings us to a consideration of the activities of the triumvirate.

(To be Continued)

Operating and developing costs at the North Star gold mine at Grass Valley, California, averaged $7.77 per ton from 1884 to the end of 1918. During that time, 1,898,584 tons of $11.47 ore was extracted and treated.

Vanadium ore imported from Peru during February amounted to 841,257 lb., valued at $2510, equal to about $6 per ton. Imports of ore from the same country in the first 15 days of March were 373,900 lb., worth $1106.

Piping that is used to carry acetylene or hydrogen should be painted a distinctive color so that it will not be possible to mistake the line for anything else.

Chromite in Wyoming, and Manufacture of Ferro-Chrome in Colorado

According to the annual report of the Vindicator Consolidated Gold Mining Co. of Cripple Creek, Colorado, three claims, 23 miles south-east of Glenrock on the C. B. & Q. railroad, were purchased from Wheeler and others in September 1918. The lease-rights were sold for $7500, and the bond called for a purchase-price of $25,000. The lease also called for a royalty of 12½% on cars at Glenrock, the amounts not to be deducted from purchase-price. In October, the owner accepted $8750 cash in lieu of the bond price of $25,000, due a year later, so the Vindicator became owner. The sellers had extracted 500 tons of 34% chromite. Some prospecting showed other lenses in the east end of the property, carrying 39% ore. During development, 610 tons were shipped, and there is available 2000 tons and over, according to the February 10, 1919, report of the Ferro Alloy Co., absorbed by the Vindicator company in September 1918. A good deal of road construction had to be done, also three surface trams—two of 500 and 1200 ft. on 36° incline, and one level of 500 ft. This work, buildings, and development cost $30,897. The purchase of lease and property cost $16,250, so the total outlay was $47,147. Chromite sold realized $9602, leaving $37,544 net expenditure to the end of 1918, reduced by February 10, 1919, to $33,602. Since January 1, $5469 has been received from ore sold. When the indicated ore is extracted, the mine will show a profit, after having paid the purchase-price of the property, development, and improvements. Californian, Oregon, and Washington chromite has a freight-rate $8.70 per ton higher than from Glenrock to Denver.

The electric smelting plant of the Ferro Alloy Co. at Utah Junction, Colorado, was purchased by the Vindicator Consolidated in September 1918 at a cost of $68,697. Up to the end of 1918 the plant resulted in an operating loss of $2270. S. B. Tyler is now in charge, and is producing ferro-chrome at low cost, considering the low capacity of 100 tons per month. When the additional 1500-kva. General Electric furnace is in operation the output will be doubled. The company has some contracts for delivery of the alloy during 1919, and is receiving orders frequently for spot delivery. Having its own chrome mine, a low freight-rate, and its own smelter the manager, Nelson Franklin, considers that the company is in a position to compete with others in the manufacture of ferro-chrome. A profitable year is expected during 1919.

Phosphate Rock

There was little change in the phosphate-rock market during March. Labor costs are one of the principal items in the mining and preparation of phosphate rock, and there has been no change in these charges; hence there has been no marked change in the price of this important fertilizer commodity. Florida land pebble, containing 68% bone phosphate, f.o.b. Tampa, Florida, was about $5 per ton; with 75%, the price was $7.50 to $8 per ton; high-grade Florida hard rock, containing 77%, f.o.b. Florida ports, was $9 to $10 per ton. Tennessee rock, guaranteed to contain 75% bone phosphate of lime, averaged $9.50 to $10. The Tennessee rock with 58 to 72%, ground so that it will pass through a 100-mesh screen, was priced at $7.25 to $7.50 per ton.—W. C. Phalen in March report of the U. S. Bureau of Mines.

Molybdenum

By H. C. MORRIS

*Persistent statements to the effect that the use of molybdenum is increasing with relative rapidity are being received from various sources, although it is not known to what extent these are based upon the war uses in parts of airplane engines, etc. It is clearly the presumption that if a molybdenum alloy was found satisfactory in these engines, it may also be desirable in automobile engines, unless the price or difficulty of working is too great. Molybdenum steel, once it is made, has many desirable qualities, but the chief difficulty with the metal seems to be in the making of the steel. The molybdenum volatilizes, is difficult to mix uniformly in the steel, and causes a red shortness responsible for a large scale loss.

Imports of molybdenum ore during February totaled 68,599 lb., valued at $48,255. The greater part came from Canada. There were no imports of molybdenum metal or ferro-molybdenum. There were no imports of ore in the first 15 days of March, none of metal or ferro.

Flotation at Cripple Creek

The annual report of the Vindicator Consolidated Gold Mining Co. contains the following data regarding its milling operations during 1918:

On company account there was hoisted 230,304 tons of crude ore, averaging $6.15 per ton. Of this quantity, 6.67% was sorted out and sent to the Golden Cycle mill at Colorado Springs. All rejects from ore-dressing operations and the Golden Cycle shaft ore-house are delivered to the flotation plant, where they are screened and all coarse waste rejected, and the residue sent to the flotation-plant crusher. During the year there were sent to the flotation plant from all sources 222,626 tons of ore, of an average assay-value of $2.13 per ton. Of this, 176,623 tons, assaying $1.42 per ton, was rejected by screening, and 46,003 tons valued at $4.18 sent to the flotation-plant crusher. There was shipped from the flotation plant 6209 tons of concentrate having a gross value of $206,255, equal to $34.21 per ton, and a net value after marketing charges of $171,038. After the deduction of all operating costs the net profit from this source amounted to $27,955. The royalty paid on flotation rights was $2578, equal to 5½ cents per ton on 46,003 tons so treated.

*Abstract from March report of U. S. Bureau of Mines

REVIEW OF MINING

PACHUCA, MEXICO

SANTA GERTRUDIS, EL BORDO, AND REAL DEL MONTE.

The Santa Gertrudis Company in London recently issued a circular, accompanied by reports on the properties by Hugh Rose and L. Chevrillon. These, in part, are as follows, with a property-map:

Mr. Rose stated that El Bordo, in which Santa Gertrudis acquired a 40% interest, is in the centre of the Pachuca district, surrounded by the most-highly productive mines thereof, and 3½ miles from the Santa Gertrudis mill, with which El Bordo is being connected by an aerial tram capable of transporting 100 tons of ore per hour. By reference to the attached sketch, it will be noted that there are four groups—El Bordo, Malinche, El Cristo, and La Zorro. The last-mentioned is on a vein of minor importance with no record of production, and is of no special interest at this time.

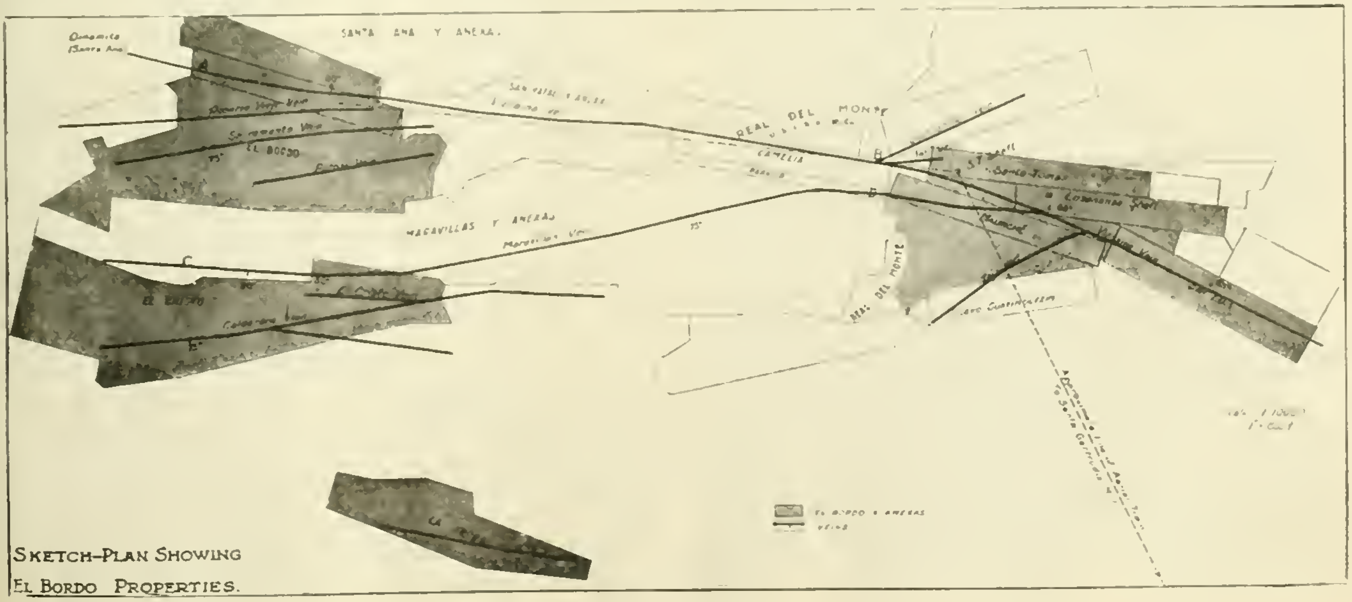
El Bordo mine has produced a large tonnage of ore in the past, and its present reserves are taken at 300,000 tons of ore averaging 1.60 dwt. gold and 17 oz. silver, with large development possibilities both in depth and laterally. Production at the beginning will be from this property alone.

The Malinche mine is practically a virgin property. The only development, done many years ago, consists of two shafts—Santa Tomas and Ensenanza—both sunk to a depth of 750 ft., where a limited amount of cross-cutting was done to the main Vizcaina vein. As this work was not at sufficient depth to reach the ore-zone as indicated in the mines to the west, these shafts are to be sunk another 250 or 300 ft., whereupon extensive development of both the Vizcaina and Maravillas veins is to be started. Particular attention is invited to the possibilities of this property.

Two strong vein-systems enter the ground at B and D (see map). On the Vizcaina to the west are located three great mines—Camelia, San Rafael, and El Bordo, as well as the smaller Santa Ana mine covering a succession of large orebodies from A to B, a distance of 8000 ft. on the strike of the vein. In the Camelia mine, 150 ft. west of the Malinche line, is an orebody 50 ft. in width, averaging 20 oz. silver per ton. The Maravillas vein, for a great many years, over a length of 8000 ft. from C to D has yielded a large quantity of ore to the Maravillas company. Near point D the vein enters the property of the Real del Monte company, where it was worked to the Malinche boundary-line, at which place the ore is reported to have averaged over 30 oz. silver for a width of 20 ft. Upon the foregoing record and information are based favorable expectations in Malinche.

El Cristo is an old mine, which has yielded a considerable tonnage of high-grade ore, and has in sight 125,000 tons of ore averaging 9.5 oz. silver, and probably capable of considerable expansion, and likely to prove a useful feeder of low-grade ore to the mill. No development will be undertaken on this group until El Bordo is in regular operation.

At the present price of silver, 101½ cents (U. S.) per fine ounce, and on the proposed basis of treating 500 tons of ore per day from El Bordo, the net mining profit is



SKETCH-PLAN SHOWING EL BORDO PROPERTIES.

estimated at an average of £30,000 ($145,000) per month, Santa Gertrudis 40% share amounting to £12,000 per month. For a time at first, owing to higher-grade ore, the monthly profit should be from £40,000 to £45,000, Santa Gertrudis share amounting to £16,000 to £18,000. It is expected, barring unforeseen delays, that El Bordo will commence production next July or August, with full-rate earnings probably reached a month or two later. Therefore it may be expected that combined profits from Santa Gertrudis and El Bordo mines will reach £35,000 to £40,000 by the coming late summer or early fall. Later on, as the grade of El Bordo ore is reduced to normal, these profits should total £30,000 to £35,000 monthly ($145,000 to $169,000).

Although not connected with El Bordo business, mention might be made of the several other properties that are being taken by Santa Gertrudis under option to purchase, after two years in which to develop. The most important of these is Espiritu Santo, which is believed to have the northerly extension of the Veta Nueva, the vein upon which within the past four years the Real del Monte company has discovered and developed a very large and rich orebody, said to contain £8,000,000 ($38,800,000) profit. At any rate, a good and strong vein has been surficially developed in Espiritu Santo ground, and it is proposed to sink the shaft a further 300 ft. and drive, on the supposition that sufficient depth to reach the main ore-zone has not been reached. Sinking will be done on a small exposure of pay-ore. Such work as the above, while entirely of a prospecting nature, is undoubtedly good business for Santa Gertrudis to undertake, having in view the great productivity of the Pachuca district and desirability of providing further sources of ore-supply for the mill.

Mr. Chevrillon said that he could only convey to the directors of Santa Gertrudis his full endorsement of Mr. Rose's report. The results obtained have so far borne out, in El Bordo proper, the expectations formed at the time of examination by the engineers; and it is gratifying to note that after a few months of development the tonnage and grade of ore available are sufficient to more than repay any past or future outlay connected with the equipment of El Bordo and the acquisition of the interest in the group. At the time of Mr. Chevrillon's visit in December last the principal orebody showed a decided tendency to persist both along the strike and in depth.

The annual report of the U. S. S. R. & M. Co., which controls Real del Monte, operating at Pachuca, contains the following:

> With the exception of the high costs pertaining to supplies, operations in Mexico during 1918 may be considered to have run on a normal basis. The two mills treated 690,000 tons of ore, approximately 58,000 tons per month. Extraction of ore from the new vein was increased from month to month, and will before long reach the anticipated regular tonnage. This ore being of much higher grade than the average formerly supplied to the Guerrero mill, has had the effect of materially raising the mill-heads, resulting in a substantial increase in profits. No difficulty is anticipated in maintaining these results. A moderate tonnage of the highest-grade ore obtained from this vein is being shipped direct to smelter. The output from this vein and from other localities, both in the Real del Monte and Pachuca districts, is capable of an increase beyond the present capacity of the two mills. This situation will be met by the additions to the mills started last year, and are now approaching completion. It is expected that by the middle of 1919 the capacity will reach 80,000 tons per month. The erection of a third mill of 15,000 tons monthly capacity is still under consideration. Tests are not completed to determine the best process to be adopted, neither do costs and deliveries of materials favor construction at this time. In view of the more stable general conditions in Mexico, and the favorable results in opening ore-reserves, the prospects for earnings in these properties are more favorable than ever before.

GOLDFIELD, NEVADA

LESSEES' RICH ORE.—EXPLORATION IN THE CONTACT.

A carload of ore each week is being shipped from the Witt-Brandon-Taylor-Mechlin lease at the Florence Goldfield, which attracted attention several months ago by the opening of a seam showing free gold over a width of from 6 to 18 in. The grade has been much lower than was anticipated when shipments were started, carload lots assaying under $100 per ton. A stope 80 ft. long has been started from the 400-ft. level, and the material is being broken for a width of from 3 to 4 ft. When first opened, assays of $400 per ton were returned from a width of from 4 to 6 ft., but recent assays have proved that a short distance above the level practically the entire value of the vein is confined to the rich seam, so the lessees are planning to raise the value of shipments by breaking ore over the narrowest possible width. The ore was opened in a drift from the top of a 116-ft. raise, and the lessees have started to explore the vein 50 ft. below to determine if the rich seam extends to this depth. Nine other lessees are working, shipments of low-grade ore being made by them at irregular intervals.

The Spearhead, Merger, and Grandma are exploring at or near the shale-latite contact. The first is raising toward the contact from the 910-ft. level and the raise, after having, in the opinion of the management, paralleled the surface of the shale, dipping west at this point, for a distance of over 100 ft. has been turned at right angles, and is expected to break into the latite within a short distance. Owing to the numerous seams of good ore found on the 910-ft. level in an intrusion of the latite into the shale it is supposed that the opening of the contact on which a large mass of quartz is known to lie, will result in the discovery of an orebody of good size and grade. Small quantities of ore of shipping grade are being saved from work at other points on this level.—— The Merger, which recently secured permission from the Spearhead company to work through the latter's shaft, has advanced a cross-cut well into Merger ground. This cross-cut is being driven to open in the Merger, the contact of the quartz-mass with the shale. —The Grandma is working at a depth of 815 ft. in the Spearhead-Grandma vein, a vein distinct from the quartz-mass lying on the shale. Although at 815 ft. the Grandma shaft is in the shale, drifts and cross-cuts driven in all directions from the shaft have failed to expose this formation again. A number of promising cross-veins have been found. The claims of these three companies adjoin and their efforts to find ore on the shale-latite contact are of interest at this time.

YERINGTON, NEVADA

WORK AT THE MASON VALLEY, BLUESTONE, NEVADA DOUGLAS, WESTERN NEVADA, WALKER RIVER COPPER COMPANY, BUCKSKIN, AND NORTHERN LIGHT.

The entire copper district of Lyon county is very quiet since the smelter at Thompson closed on March 1. All the small properties are closed, and nearly all lessees have stopped work. Locally it is thought that the smelter may not re-open until next year, although it is realized that this will depend on the foreign demand for copper. At present prices, with continued high cost of supplies and labor, it is not possible for the local mines to make profits.

The Mason Valley Copper Co. has 30 men working.

The Bluestone M. & S. Co. is reported to be making plans for increasing the size of its flotation plant, which was a big success. Concentrates were shipped to Utah smelters, as the Thompson plant is not equipped for handling such product. It is, however, thought that the smelter will be so improved before re-starting.

Nevada-Douglas development is giving good results; this is also true of the Western Nevada mine owned by the same company. Large bodies of sulphide ore have been opened in the latter, and a flotation plant is under consideration. This mine is near or at the southern extremity of the mineralized limestone belt, which is the ore-bearing zone of the district, and adjoins the McConnell mine on the south but at a lower elevation.

The Walker River Copper Co. continues drilling operations on its Empire Nevada group. Many engineers consider that this property has the brightest future of any in the district. Large tonnages of oxidized ore have been developed, and no doubt a leaching-plant will be built in the near future, as the ore is ideal for sulphuric-acid leaching process. The general formation is monzonite, and the valuable copper minerals at or near the surface are the carbonates and oxides. The ore is highly silicious, and has been in demand for converter lining, etc. Iron minerals are conspicuous by their absence. J. E. Gelder is in charge of operations.

The Northern Light, 15 miles east of Yerington, is the scene of the most recent strike in the district. This property has some of the characteristics of the Ludwig, but is not a vein. The limestone is not garnetized as in Mason Valley district proper, and the orebodies are irregular lenses in a rather narrow belt of limestone. This property has been worked almost entirely by lessees, and as the ore is usually of a grade better than 8% it has been profitable for them. The recent strike is a lens of sulphide ore reported to average over 15% copper, and more extensive than any deposits found in the past

CHLORIDE, ARIZONA

CHANGES IN OWNERSHIP AND NEW DEVELOPMENTS.

The McCracken Silver-Lead Mining Co. has taken over the Otsega mine. Development done during the past few months has opened good ore on the 100-ft. level. It is expected that the workings will be ready for stoping and shipping within a short time.

McKesson & Marinez, lessees at the Gold Trails mine, have made a shipment of ore assaying over $100 gold per ton. The company owning the property proposes to do extensive development.

The Arizona Ore Reduction Co. has taken over the Diana mine at Chloride. Unwatering and cleaning out the old workings is under way. The shaft is 200 ft. deep. The late owners took out $10,000 worth of ore.

The Cerbat Silver Mining & Milling Co. has taken over the Elkhart property at Chloride. The company proposes to spend $250,000. The Elkhart is situated on the Tennessee lode to the north, and has been developed to a depth of 600 ft. The ore is refractory, but it is believed that it can be treated by flotation. A considerable tonnage of high-grade ore has been shipped in the past.

E. F. Campbell has taken a bond and lease on the old Distaff mine at Chloride. Large shipments of rich silver ore have been made from the property in the past.

F. E. Berry has completed arrangements for taking over the interests of the Washington-Arizona mine at Mineral Park. He has completed financing, and the mine and a 10-ton mill are to be operated at once.

The Lookout mine has been optioned by A. Fuller of Phoenix. A 10-ton mill is to be erected immediately.

DIVIDE, NEVADA

SOME RECENT UNDERGROUND PROGRESS.

On its 465-ft. level the Tonopah Divide company has driven the south-east drift over 200 ft. to get under the high-grade area of No. 3 level. A station is to be cut on No. 5 level as soon as the 1200-cu. ft. compressor is erected. Shipments last week were 420 tons. William Watters is superintendent.

The south-east drift at 500 ft. depth in the Brougher Divide is out 125 ft., for the greater part in milling ore, a good distance averaging $24 per ton. It was reported that the first lot of ore was to go to the West End mill at Tonopah early this week. Gust. Hanson is superintendent.

The Gold Zone Divide has opened a number of promising seams, but has so far no great quantity of pay-ore. The shaft is to be sunk 300 ft. below the 500-ft. level.

Divide Consolidated has erected its head-frame, sunk the shaft 50 ft., and is preparing to erect a 10-drill compressor, and a hoist. W. S. Norris is manager.

The Aztec Divide has purchased a hoist and other machinery, and has started sinking. Rudolph Burton is in charge.

THE MINING SUMMARY

ARIZONA

Ajo.—New Cornelia during 1918 made a net profit of $2,527,806. This is the first full operating year. The mining profit was $4,791,180, depreciation, ore-depletion, and interest absorbing the balance. The output of copper was 46,950,139 pounds.

Duncan.—The Ash Peak Mines Co. has arranged to purchase part of the dismantled cyanide-plant of the Aurora Consolidated at Aurora, Nevada. The Ash Peak plant when completed will be of 100-ton capacity.

Miami.—The Miami Copper Co. pays 50 cents per share, $373,557, on May 15. This makes $1,120,771 for 1919, and $20,715,715 to date. The last distribution was $1.

Inspiration Consolidated during 1918 made a profit of $8,229,163, after paying taxes, compared with $11,086,732 in 1917, and $20,629,489 in 1916. Dividends totaled $9,455,736. Ore mined amounted to 5,139,132 tons, yielding 98,540,041 lb. of copper.

Phoenix.—The State Tax Commission announces that the total valuation of producing mines in Arizona, including machinery and equipment, increased from $153,385,383 in 1915 to $467,941,673 in 1918. In 1915 the valuation of mining property was 36½% of the assessed valuation of the State; in 1918 it had increased to 56%. The Commission says that the outstanding feature of the past two years' assessment of producing mines under the new method had been the large increase in valuation of this class of property brought about with comparatively little friction and a minimum amount of litigation.

Ray.—The Ray Hercules during the first 25 days of March treated 878 tons of 1.6% copper ore daily. The recovery is 80%.

CALIFORNIA

Bakersfield.—Oil shipment from Californian fields during March averaged 284,641 bbl. daily, an increase of 18,000 bbl. over February, but production was 278,665 bbl., almost similar to the previous month. Stocks declined 185,236 barrels.

Campo Seco.—The smelter of the Penn Chemical Co. near this place in Calaveras county was closed on April 1, and will probably remain idle for six or eight months, during which time extensive repairs are to be made in the mine.

Grass Valley.—Operations have been started on the proposed debris and power dam at Bullard's bar on the Yuba river, 28 miles west of Grass Valley. W. F. Mandry and associates will erect a saw-mill of a daily capacity of 20,000 ft. three miles from the site. He also has a contract for hauling machinery and supplies to the site. The dam will be 140 ft. long, and the first section 80 ft. high, backing the water 6½ miles. A double use will be made of the proposed reservoir; one for tailing from the Brandy City hydraulic mines, and the overflowing water converted into electrical energy. The mine-owners will be charged for debris storage, and the finished dam will permit of hydraulic operations on a large scale in that district.

The North Star company has commenced development of new ground on an extensive scale, following the reduced cost of steel and explosives.

There has been an exodus of miners from Grass Valley to Divide, Nevada, but as their places have been taken by newcomers the labor market has not been affected.

Nevada City.—The Monarch Consolidated quartz mine, in Sierra county, will be re-opened in the spring on an enlarged scale. The property is equipped with a 20-stamp mill and good mine plant. It was formerly a heavy gold producer.

Driving is progressing on a 4-ft. vein in the Argo quartz mine ,and a good showing is made of free gold. A new tunnel, 150 ft. below the present workings, is proposed, and if the value continues, a small mill is to be erected.

Jackson.—After the fire in the Argonaut mine revived on the 13th, drifts and the Muldoon shaft were quickly bulkheaded to confine the outbreak. Pumping and hoisting water is progressing steadily from the 4000-ft. level of the Argonaut shaft.

Redding.—All the mining equipment at the Tedoc chrome mine at Beegum, over the line in Tehama county, is being shipped to a gold mine in Arizona. The Tedoc company last season spent $40,000 building a wagon-road to haul its ore to rail, and 75 men were employed.

COLORADO

Breckenridge.—The state of the metal markets resulted in closing the Wellington zinc mine, the Climax molybdenum mine, and other base-metal producers, but increased activity in gold and silver help to keep Summit county going. Five dredges are ready for the season's work. Several gold and silver mines are reported to be yielding rich ore.

Durango.—The Lewis Mountain M. & M. Co., J. F. Warnecke, manager, has driven its tunnel 3400 ft. in the Ten Broeck property, finding vein formation in limestone at a depth of 2000 ft. The company proposes to erect a power-plant and mill. The owners of this property are Perini brothers of Denver.

On April 21, fire destroyed all buildings except the transformer-house at the Sunnyside mine at Eureka, the property of the U. S. S. R. & M. Co., causing a loss estimated at $250,000. A special train was sent from Durango to bring back 300 miners who lost all their personal effects by the destruction of the company boarding-house.

Idaho Springs.—Mining men here are optimistic as to the future price of silver, and expect a rise before long. The Randolph Gold M. M. & T. Co., composed of Denver and Cheyenne people, has acquired the Empire T. & T. Co.'s property at Empire. An examination shows 1,773,000 tons of $6.35 ore, on which a profit of $2 is expected.

Leadville.—A general strike was likely to start here on April 20 as a result of the cut in wages from $4.50 to $3.50 per day.

The threatened strike took place on the 20th. The men organized a local union. A committee will suggest $4 per day to the mine-owners, against the latters' $3.75.

During 1918 the Ibex (Little Johnny) employed 125 men, about half of normal, but the full complement is again at work. The property is leased to a number of different syndicates. Four shafts are in operation, the company looking after these. Gold ore is being extracted from the 300 to the 1200-ft. level. Some of this ore is in pockets, and is rich. One lease is yielding copper-silver-gold ore.

At the Fanny Rawlins new electric machinery has replaced the steam-plant burned last fall, and developments are reported as very encouraging. The New Monarch Mining Co. is to unwater its New Monarch shaft so as to develop the large gold-copper and silver-lead-zinc deposits worked by lessees in the upper levels. E. G. Kelly is in charge.

Rico.—The Rico Wellington, in charge of H. R. Trenholm, is sending three 100-ton lots of iron pyrite to Alabama, Florida, and Ohio acid and fertilizer-works. The ore carries 51% sulphur and 44% iron, and is free from impurities. An immense quantity is available. At a point 2500 ft. from the portal of the Mountain Spring tunnel of the Rico company, and 270 ft. below the Wellington level, a fine body of copper ore is being opened.

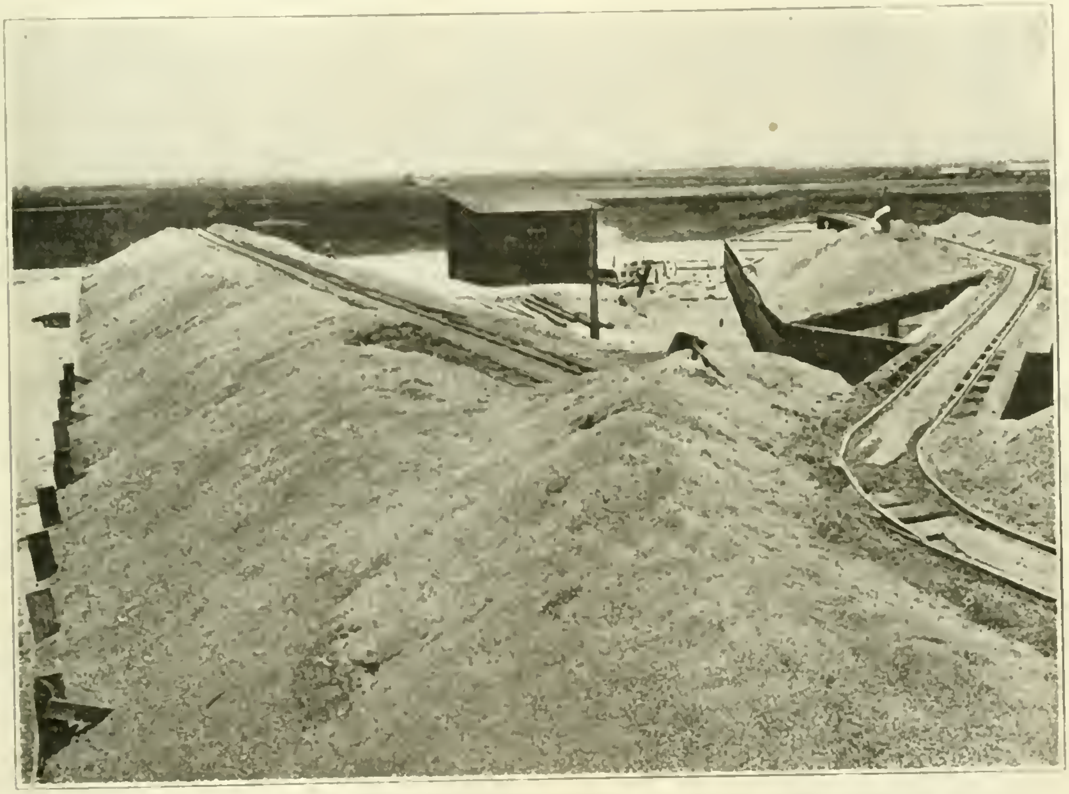
IDAHO

Burke.—It is reported that the Hercules and Tamarack & Custer mines are to resume operations at an early date. These properties, and the smelter at Northport and Lone Pine-Surprise-Pearl mines at Republic, Washington, are all controlled by Day brothers. The smelter is expected to be blown-in 30 days after the Idaho group resumes. These properties will employ 600 men when in full operation.

Moscow.—The University of Idaho School of Mines Bulletin No. 2, for January 1919, contains detailed statements on tungsten, cinnabar, manganese, molybdenum, and tin deposits of Idaho, by D. C. Livingston, and notes on the antimony deposits, by F. A. Thomson. The examination of these deposits, save those of molybdenum, were undertaken during the summer of 1918. Those interested should secure copies of this useful reference.

Mullan.—Further exploration of the West Hunter claims, between the Morning and Gold Hunter mines, is to be started on May 1. T. B. Cosgrove is in charge for the new owners. The No. 2 tunnel, in 950 ft., is to be extended to cut the vein, estimated to be 150 ft. ahead.

Salmon.—The Pope Shenon Mining Co. is to issue bonds in order to hasten construction of a 50-ton mill. The ore carries copper. A. Boulais is superintendent. Utah capital controls the property.



PILING ZINC CONCENTRATE ON THE DUMP, AT A MILL IN OKLAHOMA, SUGGESTING THE ABSENCE OF A FAVORABLE MARKET.

MISSOURI

Joplin.—Production of the Tri-State region last week was as under:

State	Blende, tons	Calamine, tons	Lead, tons	Value
Kansas	1,631	. . .	544	$97,880
Missouri	1,409	852	285	96,481
Oklahoma	4,576	. .	747	223,294
Total	7,616	852	1,576	$417,555
Average per ton	$39	$26	$60	. . . . .

The stocks on hand have become about normal, 100,000 tons. Sales last week were equal to the present weekly production, which has been greatly curtailed by the mines closing down on account of unsatisfactory prices.

MONTANA

Butte.—The East Butte Copper Co. in 1918 made a profit of $765,469, a little less than in 1915, but compared with $1,021,962 in 1917 and $1,565,768 in 1916. The cost of production was 19.71 cents per pound, a rise of 2.03 cents, but 7.86 cents more than in 1915. There was mined 184,493 tons of 4.25% ore, yielding 24,599,890 lb. of copper, 776,818 oz. of silver, and 1419 oz. of gold.

The Butte & Superior company last year made a profit of $628,348, compared with $2,450,686 in 1917. Ore mined amounted to 462,744. A review of the recent apex suit will appear in the 'Press' at an early date.

Elliston.—The Monarch Mining & Power Co., operating on Bison mountain, in Powell county, 14 miles south of Elliston, has a large tonnage of silver-lead ore. A 200-ton concentrating mill and hydro-electric plant are to be erected as soon as possible. The sawmill on the ground cuts all lumber needed. A 15 drill air-compressor and 150-hp. boilers are in commission. The shipping-point is Elliston. Auto-trucks are to be used in transporting ore and material.

NEVADA

Rochester.—Under the management of Charles Mayer, the Preston & Mayer lease on the Buck & Charley is shipping sulphide ore averaging $67 gold and silver. The ore comes from a deposit opened in a winze 90 ft. below the tunnel. The richer part of the vein is 4 ft. wide. A gasoline hoist was recently erected.

Silver Peak.—The Allied Mining & Milling Co. has been incorporated at Lewiston, Montana, with a capital of $500,000, to develop the old McNamara mine in this district. A. Heinecke of Lewiston is president, D. M. Trepp of Butte vice-president, and E. G. Ivins secretary. The property was discovered in 1875 by Mathew MacNamara, who also located the mine of the same name at Tonopah. Some work has been done to a depth of 175 ft., but a hoist and other machinery are to be put in at once.

Tonopah.—Production of the district last week, including 420 tons from the Tonopah Divide, totaled 7099 tons, valued at $120,683. Some March outputs were as under:

Mines	Tons	Silver, oz.	Gold, oz.	Profit
Belmont	9800	113,571	1080	$58,802
Mining	4915	77,780	665	35,825
Extension	9000	104,975	999	36,190

Virginia City.—Somewhat of a boom has been started here by the finding of $165 silver-gold ore at 2500 ft. from the C. & C. shaft of the Consolidated Virginia. Recent shipments of 407 tons averaged $39.07 per ton, but not from this point.

The Gould and Curry, Savage, and Chollar properties have been consolidated, also a working agreement arranged with the Best and Belcher, so that the four mines will be explored together. H. L. Slosson, Jr., will be in charge. Drilling is to be undertaken below the 1640-ft. level, the depth of the Sutro tunnel. The first drill will start on the property line of the Gould and Curry and Best and Belcher mines. Water has always made exploration costly in the past. All of these mines produced many millions in the early days.

NEW MEXICO

Alamogordo.—The Alamorgordo Shale & Oil Co. is to diamond-drill a 5-in. hole to a depth of 2500 ft., after which the size will be 4 in. J. H. Hogan is in charge.

Pinos Altos.—The Calumet-New Mexico Mining Co.'s new mill is almost ready for work. Thirty-five men are employed in the Langston mine, which is producing a good deal of ore assaying 0.24 oz. gold, 6.94 oz. silver, 1.16% copper, 8.64% lead, and 18.2% zinc. Joseph Hunt is superintendent.

SOUTH DAKOTA

Hill City.—The National Tin Corporation, through J. Robinson-Duff & Co. of New York, has issued a prospectus. The company has leased the property and mill of the American Tin & Tungsten Co The Cowboy mine has been opened to a depth of 250 ft., and 6000 tons of ore are said to be available in bins. A net return of 1.98% tin was given by assays made by the Denver Engineering Works and Henry E. Wood of Denver. A trial run of the mill yielded 50 tons of 61% concentrate.

TEXAS

Austin.—The Governor, W. P. Hobby, on April 4 vetoed the Dudley mining bill, which applied only to metals. In disapproving this measure, the Governor gave the following as his reasons: "This bill, S. B. No. 186, is disapproved because it limits the compensation allowed the State to $250 per acre for minerals other than oil, coal, gas, and lignite. There are circumstances which may arise that would cause the State to lose heavily As the result of such a law, if it might be discovered that an acre of the land from which the mineral rights are sold contained a deposit of gold, silver, quicksilver, copper, or other minerals and the same might be taken therefrom over a period of years to the value of $1,000,000, yet when $250 is paid out as royalty, that would be the extent of what the State would receive for the mineral deposit. I am in favor of the purpose of this bill to provide a way for development of the mineral resources of the State's land, and so I will submit the subject to the called session, to the end of accomplishing this and at the same time fully protecting the State."

R. M. Dudley of El Paso, the senator who was responsible for the mining bill, was much surprised at the Governor's action, saying that he had only given an excuse, not a reason, for doing so. "The Governor just went wrong, that's all," said Senator Dudley. "Mining out in west Texas is not like it is in some parts of Arizona and New Mexico. It is a pretty blank prospect. It needs stimulation and encouragement This bill was the result of hard work by some of the best mining men in the West and was modeled after the United States mining laws. It was passed by an almost unanimous vote, after thorough discussion in both Houses. The Governor seems to be using his own judgment where the representatives of the people were practically unanimous otherwise. I don't think the veto power was intended to be for the individual use of the Governor just because he did not agree with the Legislature, but the veto was to prevent hasty partisan legislation, and not to upset the deliberate and sober wish of the people as expressed through their representatives. He seems to have the deluded idea that the 'hard' metals should have the same laws as oil and gas. Oil and gas pay one-eighth of their gross production as a tax where produced from State lands, but 'hard' metals cannot do that. Such a law will absolutely prohibit the mineral development of west Texas."

Bay City.—The Texas Gulf Sulphur Co., which recently increased its capital from $1,000,000 to $3,000,000, is now operating its third well or shaft, increasing the daily output of raw sulphur to 1600 tons. Other wells are being sunk, and will be connected with the boiler-plant as rapidly as they are finished. The company is constructing storage and shipping facilities at Texas City, and will make that port its ocean shipping-point. It expects to handle not less than 200,000 tons of sulphur per year through Texas City, in addition to rail shipments.

Burkburnett.—The Burk-Waggoner well, 3½ miles west of town, came-in last week with a flow of 2000 bbl. of oil. The oil-sand was picked-up at 1630 ft., yielding oil soon after

UTAH

Alta.—Rich lead carbonates and sulphides and silver ore has been opened in the Woodlawn mine. Some months ago, at a point 1245 ft. in the main tunnel, high-grade ore was found. This yielded a good deal of ore. Then further exploration opened the new orebody. Henry Gardner is in charge.

Marysvale.—It has been announced officially that the Armour company had purchased the full interest of H. F. Chappell and of the U. S. S. R. & M. Co. in the Mineral Products Corporation. The alunite mine and potash works were closed several weeks ago, but they are to resume within 60 days. C. F. Hagedorn is chief chemist for the Armours, and R. H. Knapp superintendent of the plant here.

Tintic.—Grand Central pays 4 cents per share on April 31 This is equal to $20,000, and makes $1,822,000 to date.

The Greeley M. & M. Co. is to sink a shaft on the old Empire fissure, expected to be found at a depth of 500 ft. Theo Nicholes is manager.

WASHINGTON

Chewelah.—The winze below 1100 ft. in the United Copper mine has reached a depth of 1400 ft. It followed rich silver ore for 70 ft. During March, 100 tons of crude ore and 450 tons of concentrate were sent to smelter.

Loon Lake.—The new concentrator for the Loon Lake

Copper Co. is over 60% complete, according to W. L. Ziegler, who is in charge. A 200-hp semi-Diesel engine will drive the plant. Ball-mills will reduce the ore for treatment. A six-drill Ingersoll-Rand compressor is ready for the mine.

Nespelem.—Waste dumps left many years ago near this place by miners who could not be bothered with silver while searching for gold, are yielding good returns to the Great Metals Mining & Milling Co. This concern was formed by Big Bend wheat-farmers and old prospectors of Nespelem. A 100-ton mill was constructed last year at the falls on the Nespelem river, three miles from the townsite. Water concentration and flotation is the process, and the dumps treated to date have shown a recovery of 80%. Newly-mined ore has in many cases shown a recovery of 90%. A number of high-grade leases were worked out in the early times, but the bulk of the ore carries from 10 to 20 oz. silver per ton, with some gold and lead.

Seattle.—In Bulletin No. 4 (124 pages and map) of the Engineering Experiment Station of the University of Washington, 'A Summary of Mining in the State of Washington,' has been prepared by A. H. Fisher. The text is really a compilation, but one of much value. Part 1 is a summary of the more important metalliferous resources, together with the factors influencing their development. Part 2 is a list of mining districts, set under their principal economic metal. The other section of the book is in the nature of a bibliography, listing practically everything published concerning mining in the State. A peculiar but important omission, is the entire lack of mention of the great magnesite deposits in Stevens county. The bulletin is edited by Milnor Roberts.

MEXICO

According to the El Paso 'Herald', copies of two proposed mining laws to be submitted to the Mexican national congress when it convenes on May 1 were received at El Paso last week by American mining men having interests in Mexico. Of two bills, published in parallel columns in book form, one was prepared by the Department of Mines of the section of Industry, Commerce and Labor. The other was drafted by a commission appointed by the national congress of industries held at Mexico City last year. The one proposed by the Department is considered even more drastic than the present mining law. If passed, it would make difficult the operation of mining companies by foreigners, as it prohibits foreign companies from owning mining claims within 100 kilometers of the national boundaries, or 50 kilometers from the seacoast. Individual foreigners may own and operate claims within this zone by special permission, but companies are specifically barred unless they become Mexican corporations. The proposed bill also seeks to compel operations or forfeit the claims. In the past it has been possible to hold such claims by paying the pertenencia taxes.

Jalisco

El Favor.—At El Favor and Mololoa mines, the mills have been re-built, and 15 of 35 stamps are dropping. High-grade ore is being sent to smelters. Twenty-two cars had been shipped to the end of March, the last one being settled for $5043 net, expenses of $34.12 per ton deducted. The gross value was $217.38 per ton. Makeever brothers of New York, who control these properties, are sanguine over conditions in Mexico, and are preparing for another plant at their Candelaria mine.

El Oro.—The Mexico Mines of El Oro during the year ended June 30, 1918, made a profit of $1,272,000, and paid $960,000 in dividends. Ore-reserves decreased slightly to 416,200 tons, averaging $11.72 gold and 8.34 oz. silver per ton. The mill treated 121,793 tons, yielding $1,631,373 gold and 945,320 oz. silver.

Guadalajara.—Part of the railway to Chamela was opened last week.

PERSONAL

Note. The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Ralph W. Perry is at Tonopah.

P. K. Lucke, consulting mining engineer, is now in Mexico City.

Bulkeley Wells has arrived in San Francisco from Colorado.

Edmond N. Skinner has returned from Tonopah to New York.

Lawrence Addicks goes from New York to London on May 17.

Frederick Burbridge, of Wallace, Idaho, has been in Oklahoma.

Hennen Jennings and **W. W. Mein** are on their way to New York.

D'Arcy Weatherbe is at Toronto, he has not yet started for London.

Willet G. Miller sailed last week from New York on his way to London.

W. W. Mein is expected in San Francisco on his return from Nicaragua.

W. C. Ralston has moved from Reno, Nevada, to 25 Broad St., New York.

Joseph L. White is superintendent of the Bluebell mine, at Mayer, Arizona.

Frank H. Probert has returned from Europe to the University of California.

Harry M. Rockwell is with the International Smelting Co., at Tooele, Utah.

John W. Mercer, Major in the American Red Cross, is now at Berne, Switzerland.

W. J. Clifford, recently of the 27th Engineers, has returned to San Francisco.

C. C. Broadwater, now in London, will be returning to San Francisco early in May.

Hugh Rose, manager of the Santa Gertrudis, has returned from London to Mexico City.

G. B. Holderer recently returned to New York from an extended trip through Mexico.

I. J. Cole is making an examination of nitrate deposits near Yale, in Malheur county, Oregon.

Cecil A. Gorelangton, Captain of Engineers, has returned from Camp Humphreys to Pasadena, California.

Preston E. St. Clair Locke, head of the A. S. & R. Exploration Department, at Seattle, was in San Francisco this week.

Howland Bancroft and **B. L. Thane** have formed a partnership as consulting engineers with offices in the Crocker Bdg., San Francisco.

William Beaudry, director and manager of the Stewart Mining Co. and of the Nabob Consolidated Mining Co., at Kellogg, Idaho, has resigned.

J. R. Buchanan has been discharged from the Army as Captain of Engineers, and has resumed his position with the Homestead Iron Dyke Mines Co., at Homestead, Oregon.

C. K. Leith, professor of geology in the University of Wisconsin, has returned from Paris, where he served as mineral adviser to the economic section of the American Peace Commission.

W. B. Devereux, Jr., Major in the Air Service, has returned from overseas and received his discharge. He will resume his work with the firm of Wilkens & Devereux, in New York.

Theodore J. Hoover has been appointed Dean of the Mining Department of Stanford University, to take effect on

October 1. He will organize the department on the basis of graduate study.

George W. Blackinton, Major in the A. E. F., formerly office manager at Denver for the Sullivan Machinery Co., has been awarded the D. S. C. for extraordinary heroism at Nammes, France, on September 12, 1918.

Amor F. Keene has accepted the position as consulting engineer and a member of the New York advisory committee of the Gold Fields American Development Co., which is associated with the Consolidated Gold Fields of South Africa.

Claude Cooper, recently returned from overseas service as Captain in the U. S. Army, has been named as superintendent of the Calumet & Hecla electrolytic plant at Hubbell, Michigan, succeeding **J. C. Bryant**. Mr. Cooper was formerly assistant-superintendent of the C. & H. smelting-plant

Obituary

George F. Becker, the veteran physicist and geologist, an officer of the U. S. Geological Survey, died at Washington on April 21. He was born in New York in 1847, the son of a Dane. He graduated successively from Harvard, Heidelberg, and the Royal School of Mines at Berlin. For four years, 1975-'79, he was instructor in mining and metallurgy at the University of California, leaving to join the U. S. Geological Survey. He wrote voluminously and well on many scientific subjects, notably the origin of the South African banket and the quicksilver deposits of the Pacific Coast.

C. S. McKenzie, two weeks ago, established an office with Jay A. Carpenter as mining engineers at Tonopah, Nevada, having charge of three of the new properties at Divide; but immediately after the partnership was formed McKenzie died, on April 18. He was discharged from the Chemical Warfare Service, as divisional gas-training officer at Camp Fremont, in January. Three days after returning to Tonopah he contracted pneumonic-influenza, resulting in his death. His wife died four years ago. He was born at Melones, California, in 1889. For several years he was on the Tonopah Belmont company's engineering staff.

Joseph Esrey Johnson, Jr., had already achieved the essentials of a great career when death cut short his activities on April 4, 1919, in the 19th year of his age. He belonged to a family of iron blast-furnace men and mine managers. His father, Major J. E. Johnson, after serving with distinction in the Army of the North, identified himself with the iron mines and blast-furnace at Longdale, Virginia, with which he was connected during almost his entire business life. From him his son obtained not only a thorough training in blast-furnace practice and iron mining, but great personal courage and force of character. His mother, who survives both her husband and sons, possesses rare intellectuality, humor, and a tenderness and human sympathy which those who were privileged to know well J. E. Johnson, Jr., recognized beneath his exterior of aggressiveness and will power. His early education was obtained under a private tutor at Longdale, and this circumstance probably enhanced a natural tendency to independence of character and individuality, which, however, under the control of his straight thinking and clear analysis never allowed him to go far astray. If once he set his mind to a problem, however knotty, he scored a bull's-eye before the subject was dropped. His manner of attacking a subject involved first mastering the details of the available knowledge; then putting this acquired information to one side with an untrammeled mind blazing out a path of his own, so clear, so well-defined, and expressed in such simple terms that he illuminated the whole subject without distorting the original data or discussion. His two books on the iron blast-furnace together form the most comprehensive, the most enlightening, and the most useful treatise on the subject ever produced in any language. But his ability did not end with the mastery and elucidation of principles enunciated by his predecessors. His own discoveries and inventions in the metallurgy of iron have established his reputation. Many stories are told of Esrey Johnson's personal courage; probably the most spectacular is the prevention of an attempted lynching in Virginia in 1908. A young white girl had been murdered by a colored boy under those horrifying circumstances, with accounts of which we are all too familiar. Johnson was not only manager of the mines and the blast-furnace in that locality but was one of the officials of the county. He organized the search whereby the negro was captured, brought to Johnson's office and a confession of the crime wrung from him. The usual crowd collected quickly, thirsting for vengeance in the form of hanging or burning. Practically alone, Johnson held this crowd at bay for several hours, sometimes mixing with the crowd and pledging his honor that the colored boy should be tried and executed according to law, sometimes pleading for the good name of the community, and when necessary, 'showing his teeth' to those who can understand no other argument for the curbing of their personal inclinations or intentions. He has told me that he expressed himself in substantially these words: "I am going to see this nigger hung in accordance with law and order. If you fellows try to prevent me, you may get me, but I will get some of you first." I am sure that at this point in the argument he smiled, for he had an expressive smile which endeared his friends to him, and which he could make very convincing when he desired. Finally, the morning train arrived on the track just outside Johnson's office. He realized that this was the moment when a coup would be attempted, but he had already laid his plans with the sheriff over the long-distance telephone. The train stopped exactly where he had directed. He rushed the trembling culprit by the crowd of angry heavily-armed men into an empty railroad-car occupied only by the sheriff. The door was barricaded behind the three men and the train pulled out before a rush could be accomplished. Another crowd had to be over-awed at the entrance of the county courthouse, where the judge had called a special term of the court. To him Johnson delivered his prisoner and made good his promise that justice should be done. Johnson led a white life. There was no weak spot in his professional or personal armor of honor and sincerity. His home life was unusually happy and congenial. He married Margaret C. Hilles of Wilmington, Delaware; she was not only his friend and comrade, but an intellectual stimulus and helpmate in a busy life. Johnson always identified himself with the public work of his profession and community. He was for many years a member of the principal engineering societies, and especially of the American Society of Mechanical Engineers, the Mining and Metallurgical Society of America, and the American Institute of Mining and Metallurgical Engineers. B. S.

The annual meeting of the American Zinc Institute is to be held at St. Louis on May 12.

The Kansas City club of the American Association of Engineers at its meeting on March 21 elected the following officers: chairman, J. E. Jacoby; vice-chairman, W. H. Cast; secretary, R. N. Clark; and treasurer, S. M. Bate.

The Washington chapter of the American Association of Engineers at its Seattle meeting on March 25 elected the following officers: president, Harry Stevens; first vice-president, A. Y. Hess; second vice-president, Clegge Thomas; secretary, E. L. Howard; and treasurer, O. M. Sutherland.

THE METAL MARKET

METAL PRICES

San Francisco, April 22

Aluminum-dust, cents per pound	40—60
Antimony, cents per pound	8
Copper, electrolytic, cents per pound	15½
Lead, pig, cents per pound	5¼—6¼
Platinum, per ounce	$100
Quicksilver, per flask of 75 lb.	$75
Spelter, cents per pound	8
Zinc-dust, cents per pound	12½

EASTERN METAL MARKET

(By wire from New York)

April 22.—Copper is inactive and easy. Lead is listless though steady. Spelter is dull and lower.

SILVER

Below are given official (not Government) quotations, in cents per ounce, of silver 999 fine. In order to make prompt settlements with smelters and brokers, producers allow a discount from the maximum fixed price of $1.01½, hence the lower price. The Government has not fixed the general market price at $1 but will pay this price (as from April 23, 1918) for all silver purchased by it. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange. On August 15, 1918, the Treasury announced that the maximum price was fixed at $1.01½ per ounce. The British government fixed it maximum at 49½ pence on September 2, but on November 12 this was changed to 48¾, on December 13 to 48 7/16, and on February 20 to 47¾ pence. On March 25, on account of the low rate of exchange, the London price was adjusted, with a minimum of 95 cents, resulting in daily fluctuations.

Some silver authorities predict that silver will work higher after May 1 according to the 'Boston News Bureau'. On that date Government control over the metal ceases in the domestic market. At present the Government will not receive the metal for assay unless it is sold to it. After May 1 the Government will either buy metal or return it to producers. This however, only applies to domestic silver. The embargo has not yet been lifted on shipments abroad.

An official statement was made in the Imperial Legislative Council of India that during the last four years, 1200 millions of rupees (1 rupee = 30 cents) have been drawn from the Mints. This quantity, vast as it is, represents less than one rupee per annum for each inhabitant of that Empire.

The stock of silver at Shanghai on March 8 consisted of 30,600,000 oz in sycee and 10,800,000 dollars, compared with 30,500,000 oz in sycee and 15,900,000 dollars on the 1st.

TIN

Prices in New York, in cents per pound. The monthly averages in 1918 are nominal. On December 3 the War Industries Board fixed the price to consumers and jobbers at 72½c. f.o.b. Chicago and Eastern points, and 71½c. on the Pacific Coast. This will continue until the U. S. Steel Products Co.'s stock is consumed.

Tungsten. An improvement in sentiment and in business done in the last week is reported. As high as $8 per unit is said to have been paid for concentrates. High-grade scheelite is obtainable at $10 per unit. One dealer states that tungsten metal has sold at $1.50 per lb. Another dealer says that unless he wanted ferro-tungsten badly he would not offer as much as $1.25 per lb. of contained tungsten.

The United States Steel Corporation during 1918 reported the following production: iron ore mined, 28,332,939 tons; limestone quarried, 5,141,365 tons; coal mined, 31,748,135 tons; coke made, 17,757,630 tons (by-product coke 43%); pig-iron and ferro-alloys, 15,940,954 tons; steel ingots, 10,583,493 tons; rolled and other finished products, 13,849,483 tons; spelter, 41,715 tons; sulphate of iron, 42,321 tons; fertilizer, 12,022 tons; and cement, 7,287,000 barrels.

Eastern Metal Market

New York, April 16.

A decidedly easier tone has developed in nearly all of the metals as the week progressed, resulting in lower prices

Antimony has not changed.

Copper demand has decreased decidedly, but prices have not fallen much, and are fairly firm at slightly lower levels.

Lead has been reduced, with little increase in demand as a result.

Tin is still stagnant and under control.

Zinc is inactive, and prices have eased off on light demand.

ANTIMONY

The market is unchanged and is fairly firm at 6.62½ to 6.75c. per lb., New York, duty paid, for Asiatic grades.

ALUMINUM

Quotations are nominally unchanged at 29 to 31c., New York, for No. 1 virgin metal, 98 to 99% pure, with about 2c. per lb. less for re-melt metal of the same analysis.

COPPER

The market has turned quiet, and the demand and buying in evidence a few weeks ago has largely disappeared. This is attributed almost entirely to the probability that consumers have provided for their immediate wants, which could not be very large or expansive as to the future under present conditions. The market is fairly firm, however, and the drop in quotations has been small and mostly by small interests so far. Electrolytic copper is quoted at 15.25c., New York, for early delivery, with Lake at 15.50c., a decline in the week of only ⅛c. The export situation is unchanged. There is some demand, mostly from England, with a little from neutral countries, mostly Scandanavian. A report is current that the British government plans to sell its copper at the market-price, and will thus be in a position to undersell any new offerings. British stocks of copper on April 1 are reported as 48,702 long tons, a slight decline from those a month before.

LEAD

The American Smelting & Refining Co. reduced its price for lead from 5.25 to 5c., New York, or 4.75c., St. Louis, on April 9, much to the surprise of the rest of the trade. It was entirely unexpected, because conditions were not regarded as bad, and it is believed that production cannot thrive at a price below 5c. The 5.25c. price was therefore considered as justified and sound. The real cause for the decline seems to have been the Mexican output, and the inability of its absorption by foreign interests, particularly the British. Mexican lead could be delivered at American ports, duty paid, in competition with the American product. Business in general has been small, and the reduction has not brought out purchasers. On Monday there was a substantial inquiry for future delivery, but sellers are not eager to negotiate this position. Yesterday, Tuesday, there was good inquiry, involving 500 tons, for prompt delivery. British Government stocks on April 1 were 96,456 tons, an increase of nearly 100% over those on hand at the middle of December. The outside American market is 4.95c., New York, or 4.75c., St. Louis.

IRON AND STEEL

Steel producers are booking but little new business, and do not seem worried about the future course of prices while they await the outcome of the price muddle at Washington as to Government aid to resumption in buying of steel. The scale of operations is gradually declining, with the U. S. Steel Corporation's plants in the Chicago district working at less than 74% capacity, against 80% a week ago. Most of the independent companies of the country are operating at 40 to 45% of capacity. Foreign trade in steel is insignificant, but prospects for locomotive orders are good, with every industrial country short of motive power. American rails for export are now quoted at $55 to $57 per ton, against $45 to $47 for domestic consumers. Pig-iron sellers, especially those making basic iron, see little prospect of an active market for several months. Revised figures of the 1918 steel ingot output makes the total 815,000 tons larger than earlier estimated, or 43,027,000 tons.

TIN

The market continues stagnant and devoid of interest from a market point of view. There is but one price, and that is the controlled one of 72.50c., New York. With American tin out of the market, there is nothing left but the allocated metal, all of which is said to have reached this country. An evidence of this is that there have been no arrivals at Atlantic or Pacific ports so far in April. The absorbing topic is the date on which a free open market will again prevail. As to this there are all sorts of guesses. Some give the date as May 1, others at June 1, and still others at July 1; while there is also a small number who contend that it will be months before import restrictions are removed. The majority of those best informed or qualified to express an opinion hold to June 1 as the probable date. It ought to be not later than this, they argue, so that the gap between the possible arrival of tin from the Far East and the absorption of the allocated metal may be as small as possible and thus prevent a wild or excited market. There are already offers of metal for shipment from the East as soon as restrictions are lifted. The London quotation yesterday for spot Straits was £223 per ton.

ZINC

The market has turned weak, due largely to a decided lack of demand from all classes of consumers, and to some pressure to sell by a few producers or dealers. Prime Western for early delivery is quoted at 6.15c., St. Louis, or 6.50c., New York, with the probability that this would be shaded to 6.10 to 6c., St. Louis. The uncertainty in the steel market, particularly as to prices for sheet-bars, is one cause of lack of demand from the galvanizers. Zinc stocks in Great Britain in the hands of the Government on April 1 were 27,676 tons of ordinary grades and 10,371 tons of high grade metal.

ORES

Ferro-silicon: The 50% alloy is obtainable at $90 per ton, delivered, on contract or spot requirements. A 15%, guaranteed 14 to 16%, electric ferro is obtainable for $55 per ton, delivered. The maker of this alloy also offers a silico-manganese of 20 to 25% silicon and 50% manganese, low in carbon and phosphorus.

Manganese: Indian manganese ore is offered at 55c. per unit at the Atlantic seaboard, the lowest price in many months. No sales are reported yet.

Manganese-Iron Alloys: Domestic 80% ferro has sold as low as $110 per ton, delivered, but it was re-sale material Producers continue to quote $150 delivered for 78 to 82% alloy, less $2 per unit under 78%. Spiegel is quoted at $40 to $45, delivered, depending on quantity and analysis. Business is very light in either alloy.

Molybdenum: The market is lifeless, with quotations nominally unchanged at 80 to 85c. per pound.

Company Reports

HECLA MINING CO.

Property: mine and mill at Burke, Idaho.

Operating Official: J. F. McCarthy, general manager.

Financial Statement: the income in 1918 was $4,035,339, of which $2,054,717 was profit, taxes, etc., deducted. The surplus is $2,943,962.

Dividends: these amounted to $350,000, compared with $1,600,000 in 1917. The total to March 1919 is $7,405,000.

Development: new work covered 13,566 ft. The shaft was sunk to 2000 ft., station cut, and driving toward the ore started. Reserves are 1,180,058 tons in the Hecla, and 404,057 tons in the Ore-Or-No-Go.

Production: a comparison with previous years follows:

	1918	1917	1916	1915
Ore shipped, tons	379,703	374,213	250,559	116,075
Ore milled, tons	326,809	328,696	210,727	120,461
Lead, per cent	48.55	48.77	49.25	47.55
Silver, ounces	30.06	30.00	29.30	26.10
Zinc, per cent	4.50	7.65		...
Lead, pounds	51,035,676	44,363,559	40,217,573	24,917,867
Silver, ounces	1,590,062	1,366,960	1,195,841	692,414
Zinc, pounds	133,341	507,888		

YUKON GOLD CO.

Property: gold-bearing gravels, dredges, hydraulicking plant, ditches, and power-plants in Alaska, California, Idaho, and the Klondike.

Financial Statement: the revenue in 1918 was $2,283,862. Working costs were $1,980,117, leaving an operating gain of $303,745. After paying royalty, interest, and general charges, the profit was $45,899. Depletion and depreciation totaled $921,420, so the year ended in a deficit of $875,521. Assets include $409,362 for supplies, $1,863,990 advances to Elkoro Mines Co. in Nevada, $259,525 for accounts collectable, $204,653 for bullion in transit, $938,630 cash, and $249,000 in U. S. Liberty and Canadian Victory bonds. Liabilities include $195,877 for accounts payable, and $5,000,000 to the Yukon-Alaska Trust. The excess of assets over liabilities, including all items, is $4,255,576. Note No. 2 for $625,000, due the Trust, due on February 1, 1918, was eventually extended to February 1, 1926. Note No. 3, of like amount, was liquidated.

Production: details will be given in another issue of this journal. In 1918, the dredges and other plant recovered gold worth $2,283,862.

JUDGE MINING & SMELTING CO.

Property: mine, mill, and electrolytic zinc plant at Park City, Utah.

Operating Officials: G. W. Lambourne, general manager; O. N. Friendly, general superintendent; J. T. Ellsworth, zinc plant superintendent.

Financial Statement: the revenue in 1918 totaled $1,090,342, plus the previous balance of $133,840. All expenditures were $912,002, and after paying dividends the balance remaining was $72,180.

Dividends: four No. 31-34 absorbed $210,000, making $2,310,000 to the end of 1918.

Development: the year was a trying one for the mine, on account of abnormal conditions, and only half of the orebodies were worked, and these in the dry areas. If operations had been normal the output could have been doubled. On three veins, on four levels—900 to 1400 ft.—there was 5761 ft. of work done.

Production: crude ore sold amounted to 9633 tons, and ore milled 40,622 tons. Metal production was 490 oz. gold, 508,434 oz. silver, 7,931,566 lb. lead, and 371,036 lb. copper, also 1310 tons of 99.9% spelter. These sold for $1,061,642, making $9,337,660 to date. There was on hand or in transit at the end of the year, 801 tons of high-grade spelter, 1000 tons of zinc concentrate, and 1200 tons of residue.

SILVER KING CONSOLIDATED MINING CO. OF UTAH

Property: mines and mills at Park City, Utah.

Operating Officials: Solon Spiro, general manager; H. A. Lee, assistant.

Financial Statement: the balance on January 1, 1918 was $239,086, and receipts during 1918, $570,241, (including $266,265 from sales of shares), making a total of $809,327. All disbursements were $762,619, leaving a balance of $46,708 for 1919.

Dividends: No. 19 absorbed $70,000, making $1,562,705 since 1913.

Development: the principal interest at the property lies in driving the Spiro tunnel, which was advanced 4001 ft. last year, to a point 9001 ft. from the entrance. Most of the distance was in Woodside shale, but in October this formation gave place to limestone, alternating with bands of shale. The tunnel will eliminate shaft-sinking, hoisting, water troubles, and the surface transportation of ore and supplies.

Production: the California-Comstock mill was remodeled, and by December was at capacity of 150 tons daily. Crude ore sold—4032 tons—assayed 0.037 oz. gold, 38.63 oz. silver, 22.10% lead, and 1.04% copper, worth $49.45 per ton. Concentrate—869 tons—contained 0.059 oz. gold, 58.23 oz. silver, 37.45% lead, and 1.35% copper, worth $88.14 per ton. Total sales were $275,971.

VINDICATOR CONSOLIDATED GOLD MINING CO.

Property: gold mines and works at Cripple Creek, Colorado; chrome mine in Wyoming, and ferro-chrome reduction plant in Colorado.

Operating Officials: G. A. Stahl, general manager; W. E. Ryan, general superintendent; S. B. Tyler, metallurgist at ferro-chrome plant.

Financial Statement: ore sales, lessees' royalties, and sundries during 1918 totaled $1,175,471. The operating profit was $538,951. Current assets total $574,928, and liabilities $32,724, giving a net working capital of $542,203. There was spent on a chrome mine in Wyoming $45,671 and in purchase of the Ferro Alloy Co.'s works in Colorado $68,897.

Dividends: two absorbed $60,000, making $3,772,500 to the end of 1918.

Development: new work in the Vindicator and Golden Cycle mines totaled 5113 ft., of which 2899 ft. was by lessees. Total openings are 50 miles. On No. 20 of the Golden Cycle, 4240 ft. has exposed no commercial ore, so work was discontinued. As it was only possible to do a moderate amount of development in the mines, reserves were greatly depleted, the total now being 104,230 tons.

Production: 230,304 tons of crude ore was hoisted, on company account, producing 21,392 tons of shipping ore valued at $1,166,295; and 53,463 tons of lessees' ore, yielding 24,320 tons, worth $463,514, making a total of $1,629,809. Further reference to development, flotation, and chrome will be found in other issues of this journal.

ARIZONA COMMERCIAL MINING CO.

Property: mine at Globe, Arizona.

Operating Official: R. R. Boyd, mine superintendent.

Financial Statement: during 1918 the operating profit was $270,158, less $156,912 for depletion, leaving $113,246. In 1917 the net total was $464,751.

Dividends: the total was $262,000.

Development: new work covered 6729 ft., nearly double that of 1917. Results in the east end of the mine were so favorable that a new shaft is being sunk and is now down over 240 ft. The upper portion has been concreted. On No. 15 level—the lowest developed—west of the fault a vein of more than normal width and value than ore in the eastern section of the mine, has been opened. Water pumped totaled 311,000,000 gal., a decrease of 56,000,000 gal. The maximum flow on November 1 was 1,202,500 gal., and minimum on October 13 was 692,500 gal. The apex litigation with the Iron Cap Copper Co. has already been referred to in this journal.

Production: the last two years compare as under:

	1918		1917	
	Tons	Copper %	Tons	Copper %
Smelting ore.	11,712	10.26	12.686	9.64
Concentrating ore	51,052	4.86	27,015	4.52

The totals were 62,796 tons of 5.8% and 39,702 tons of 6.15%.

Concentrating ore goes to the Old Dominion mill.

UTAH CONSOLIDATED MINING CO.

Property: mines at Bingham, Utah.

Operating Official: Fred Cowans, manager; A. S. Winther, mine superintendent.

Financial Statement: sales of metal in 1918 realized $3,067,919. Deducting all charges, and adding sundry receipts, the profit was $252,761. Litigation with the Utah Metal and Utah Apex companies cost $101,155. The former trouble has been settled. Current assets total $2,130,981, and liabilities $317,213.

Dividends: $450,000, making over $12,700,000 to date.

Development: new work covered 21,067 ft. The most important exploration was in opening 1400, 1500, and 1600-ft. levels off a vertical winze from 1300 ft. The copper orebodies improved in metal content as follows from 1200 to 1600 ft., inclusive: 1.90%, 2.30%, 2.36%, 2.37%, and 2.65%. These shoots are in limestone. The lead shoots at 1400 and 1500 ft. are maintaining their width and value. Reserves consist of 277,939 tons of 2.33% copper, 0.78 oz. silver, and 0.048 oz. gold ore; 29,591 tons of 15.93% lead, 5.23 oz. silver, 0.058 oz. gold, and 0.8% copper ore, an increase; and 526,000 tons of 1.63% copper, 0.55 oz. silver, and 0.042 oz. gold ore. Flotation tests are being made on the last class of ore. The Yampa mine was purchased for $100,000, and is developing satisfactorily. An option is held on the Utah Lead & Copper Co.'s claims.

Production: shipments to the International smelter at Tooele were 221,651 tons of copper and 31,725 tons of lead ores, yielding 8,476,197 lb. of copper, 7,812,653 lb. lead, 306,152 oz. silver, and 13,307 oz. of gold.

CONSOLIDATED INTERSTATE-CALLAHAN MINING CO.

Property: mines and mill at Interstate, Coeur d'Alene region, Idaho.

Operating Official: C. W Newton, mine manager; L. J. Fogle, mill superintendent.

Financial Statement: the income in 1918 amounted to $1,228,616. Operations cost $936,678, leaving a profit of $291,938, less $31,650 for construction, etc. After paying dividends, the surplus of $556,992 at the end of 1917 was reduced to $254,552 by January 1919. For a greater part of 1918, operations were on half capacity.

Dividends: one of 50 and one of 75 cents per share, amounting to $456,222, were paid, making $6,966,082 since April 1915.

Development: new work amounted to 5389 ft., also 20,000 cu. ft. of station and skip-chutes. The three-compartment shaft was sunk to No. 9 level, a total depth of 1100 ft. below No. 4 level, the main working-tunnel. Development at this depth added considerably to the resources of the mine, proving that the lower levels maintain high-grade zinc-sulphide ore. The mine is in splendid condition for future heavy production. In the mine is 293,000 tons of ore of average grade, and on dump is 125,000 of 10% zinc tailing.

Production: this may be summarized as under:

Ore mined, tons	85,363
Crude ore shipped, tons (48.3% zinc, 3.46% lead) . .	2,757
Crude ore shipped, tons (54.7% lead, 19.91 oz. silver)	1,634
Ore concentrated, tons (6.51% lead, 19.64% zinc, 2.21 oz. silver)	69,002
Tailing concentrated, tons (2.11% lead, 11.02% 0.86 oz. silver)	84,065
Contents of all products:	
Zinc, pounds	40,891,881
Lead, pounds	12,098,429
Silver, ounces	202,850

The gross value, as sold to smelters, was $1,866,444, compared with $5,153,398 in 1918. The Graselli Chemical Co. takes the zinc until June 1, 1919; and the Ohio & Colorado S. & R. Co. at Salida takes the lead-silver ore until 1920.

NORTH STAR MINES CO.

Property: mines and mills in Grass Valley district, California.

Operating Officials: A. B. Foote, superintendent; R. H. Bedford, in charge of North Star mine; R. E. Tremoureux, in charge of Champion mine, Nevada City.

Financial Statement: gold realized $1,046,797 during 1918, and adding the previous balance of $989,408, plus sundries, there was available $2,072,536. Operations cost $989,128, and improvements, etc., $32,759. After paying two dividends the balance carried to 1919 was $950,648. This sum consists of cash, $137,352; investments, $671,430; bills receivable, $61,000; and supplies, $80,866.

Dividends: No. 54 and 55, equal to 4%, absorbed $100,000, making $5,437,040 since 1884.

Development: North Star mine—the 3400, 4000, 4400, 4700, and 5000-ft. levels produced most of the ore. The yield was $3.64 per ton less than in 1917, due to unfavorable conditions, and the poorer and less uniform quality below 4000 ft. Bunches of rich ore are noticeably absent. No development was done between March and September. A re-estimate of reserves reduces the positive ore by 100,000 tons, making them equal to two or three years for the mill. Prospects for additional ore, both on and above 4000 ft. and at the bottom of the mine—6300 ft. are very favorable. The X vein at 6300 ft. has been opened for 1000 ft. It is rather irregular in value, and difficult to separate from waste. The outlook for 1919 is considered encouraging.

Champion mines—for the first time this property gave a profit amounting to $8000. Nearly all of the ore came from the 2400 to 2700-ft. levels of the Providence mine. Apart from the 2700-ft. orebody, which is developing favorably, exploration revealed nothing of value, and the outlook is not promising. The Champion venture has been disappointing.

Production and Cost:

	North Star	Champion
Ore mined, tons	130,445	41,300
Waste discarded, per cent	7.6	. . . . .
Ore treated, tons	99,550	41,300
Value per ton	$7.79	$6.56
Extraction, per cent	94	. . . . .
Cost per ton mined	$7.29	. . . . .

The cost of development was only 9 cents per ton, against 65 cents in 1917; so if the equivalent had been spent in 1918 the total cost would have been $7.85 per ton, compared with $7.19 in 1917, $5.43 in 1914, and $5.20 in 1913.

Book Reviews

Making the Small Shop Profitable. By John H Van Deventer. Pp. 110, ill, index The McGraw-Hill Book Co., Inc, New York For sale by 'Mining and Scientific Press'. Price, $1.75.

This book comprises articles and other material from 'The American Machinist'. Machine-shop practice and allied subjects from pattern-making to painting the completed device are discussed, with particular reference to the small shop. About half the book is devoted to sketches of various 'shop kinks'.

Metal Statistics, 1919. Compiled by C. S. J. Trench and B E. U. Luty. Pp. 384 American Metal Market Co., New York, 1919. For sale by 'Mining and Scientific Press'. Price, 50 cents.

This is one of the most useful of our desk references, especially as prices and production of metals are given for many years. The publishers of this annual issue what they term the 'steel and metal trio'—the 'American Metal Market', daily; the 'Steel and Metal Digest', monthly; and 'Metal Statistics', yearly. Any one wishing to learn anything about any of the metals will find it in this work, also a long list of manufacturers and dealers.

Oil, Paint and Drug Reporter Year-Book, 1918. Pp. 321, charts. May be obtained from Oil, Paint and Drug Reporter, Inc, 100 William street, New York.

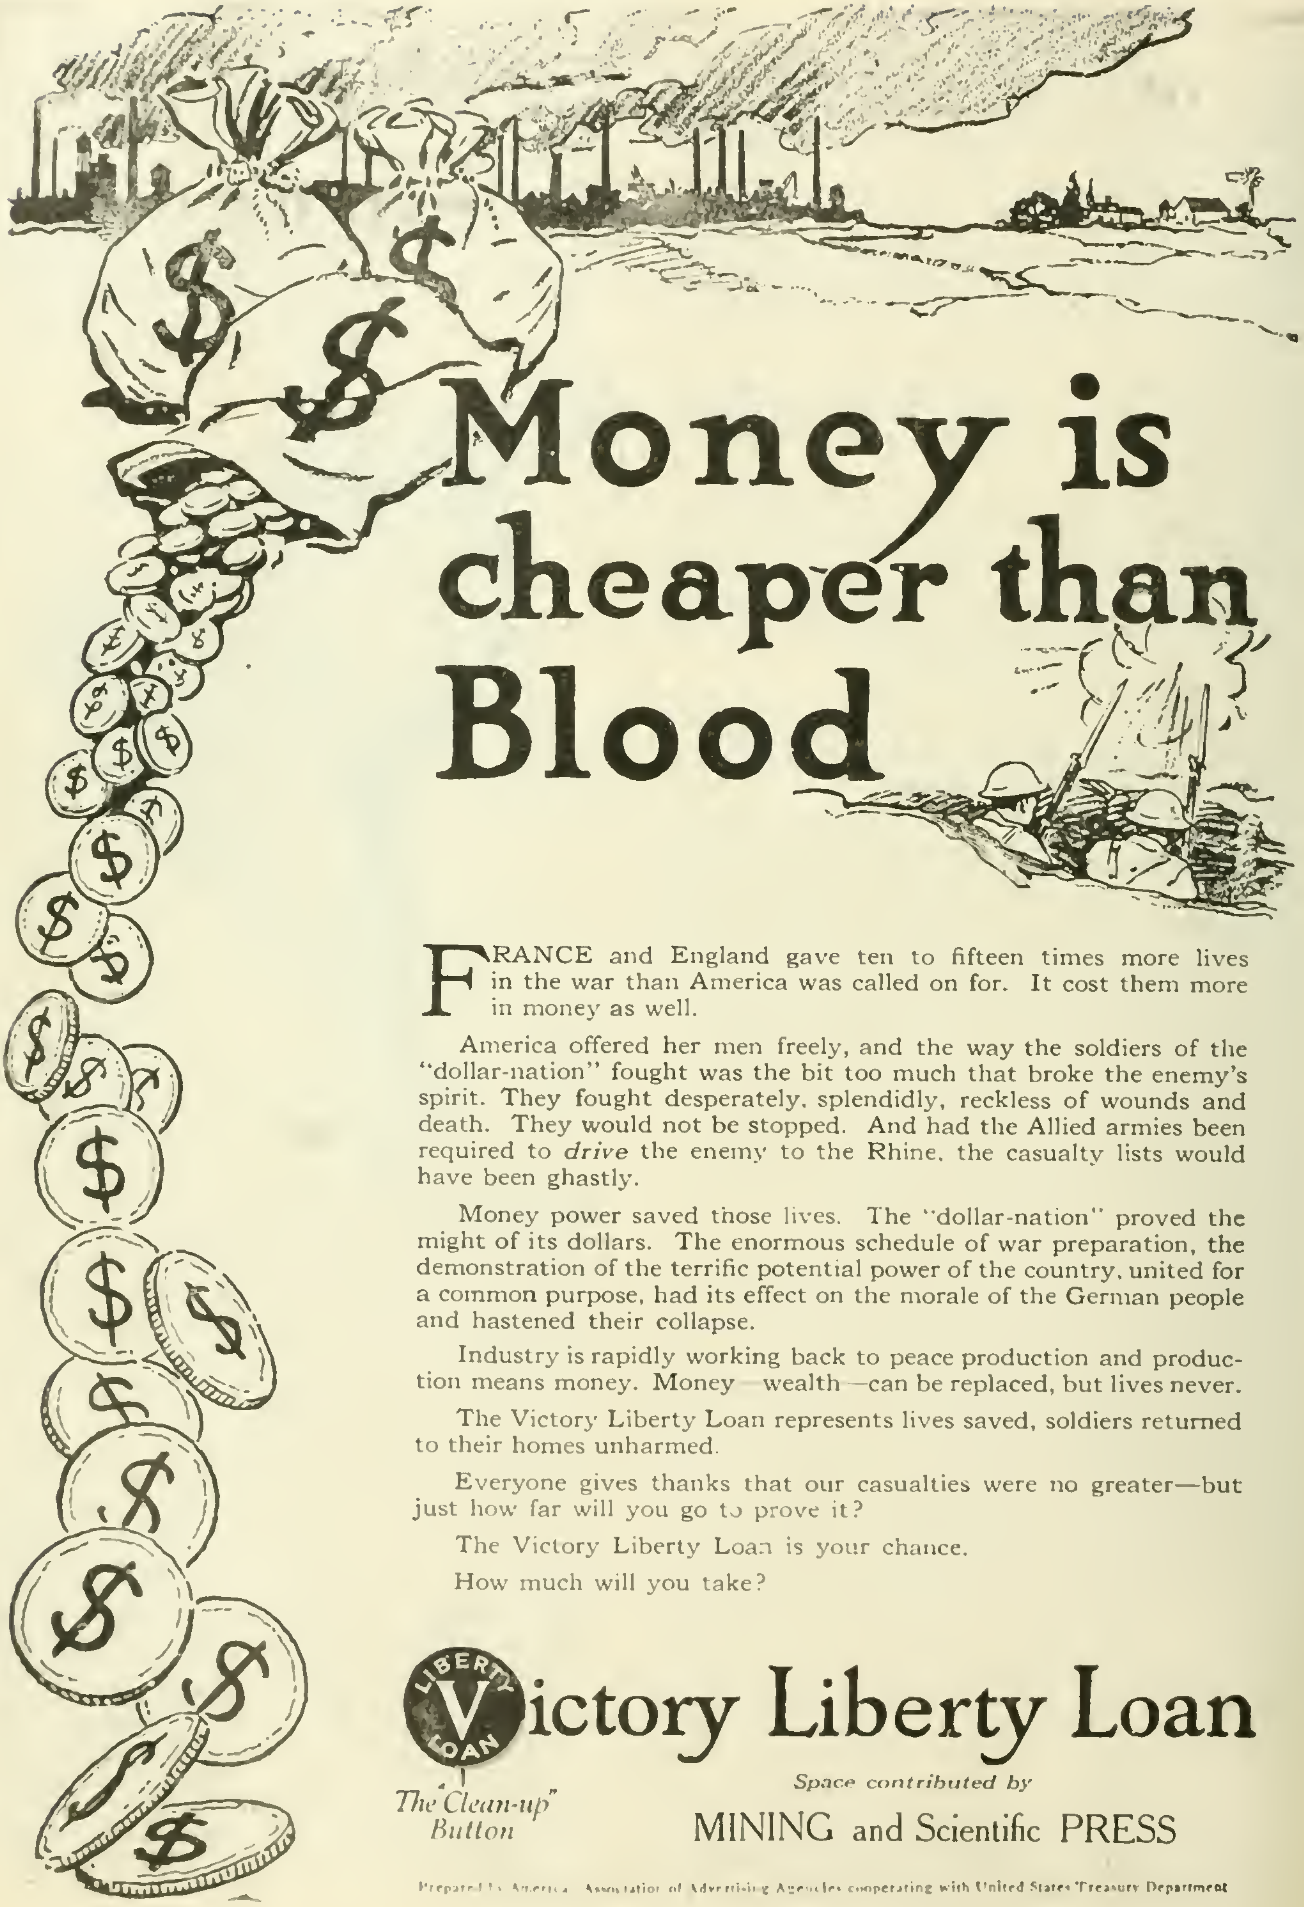
Among our valued weekly contemporaries is the 'Reporter', published by the above firm. In it is given an immense amount of information on the state of the chemical, oil, and mineral markets, our only adverse comment being the alternation of reading matter with advertisements. The Year-Book is an all-the-year encyclopedia for desk use, from which we will abstract from time to time, and also keep right at hand. The comparison of prices from 1914 to 1919 is of great value; so is the matter on trade, patents, dyestuffs, drugs, fertilizers, oils, paints, and the like. The editors' names are not given, which is rather an oversight.

Physics and Chemistry of Mining and Mine Ventilation. Second edition, revised and enlarged. By J. J. Walsh. Pp. 219, ill., index. D. Van Nostrand Co., New York, 1918. For sale by 'Mining and Scientific Press'. Price, $2.

The author is mines inspector at Wilkes-Barre, one of the coal centres of Pennsylvania, and this book is intended to be a practical handbook for vocational schools, and for those qualifying for mine foreman and mine-inspector certificates. We recently published some data on ventilation in the mines of the Coeur d'Alene, Idaho, and at the United Verde Extension mine in Arizona, so this subject is of much interest. Metal-mining companies will find herein much of value. The fundamental laws of matter, motion, liquids, heat, and gases, including one on the barometer, occupy the first ten chapters. No. XI, on the sampling and analysis of mine gases, is new matter. It includes the preparation of reagents and description of apparatus. Sixty-four pages are devoted to mine-ventilation problems, which discuss air pressure, gages, friction, air-currents, fans, shafts, doors, and regulators. In view of the recent fire at the Argonaut mine in California, the chapter on mine fires is apropos and instructive. Air consists of 20.93% O and 79.04% N, plus 0.03% CO_2, and after a fire is sealed it will burn brightly until it has consumed 3 to 4% O, after which the flame diminishes, finally dying away when the O has fallen to 13%; then a smoldering fire exists, as is the case in several American metal mines today. After each chapter in this book are a number of questions and answers, and all the problems discussed are worked out in detail, leaving nothing to be understood Mr. Walsh's presentation of the subject is well worth-while.

Mineral Deposits of South America. By B L. Miller and J T Singewald Pp. 589, ill, maps, index McGraw-Hill Book Co, New York, 1919. For sale by 'Mining and Scientific Press'. Price, $5

Most Americans, even mining men, when asked about the mineral deposits of the southern continent, show only a vague idea of that country, in spite of the fact that there are numbers of great copper, gold, iron, manganese, and nitrate properties in full production The authors of this much-wanted work made an extended trip through Bolivia, Brazil, Chile, and Peru, also rapid trips through some of the other republics, during 1915. In the 'Bulletin' of the Pan-American Union and our New York contemporary they published their observations. Additional to their own studies, the authors have been aided largely by many government departments, mining companies, and individuals in order to bring the subject-matter up to date. In the first chapter is a review of the economic geology of South America, in which it is said that the continent possesses both varied and rich deposits, and the mineral industry has not reached the state of development of that of Europe and the United States. Inadequate means of transportation, lack of exact information, and lack of capital are the causes that have hindered exploitation. Then follow 11 chapters covering a résumé of mineral production, topographic and geologic features, distribution of deposits, and details of each class of ore worked, in Argentina, Bolivia, Brazil, Chile, Colombia, Ecuador, the Guianas, Paraguay, Peru, Uruguay, and Venezuela. Each chapter has a small map showing positions of the mining districts, and each has a complete bibliography, Chile having 219 and Peru 218 references. It is impossible to review this complete work as it should be, but suffice it to say that the lack of knowledge of South America should be remedied thereby.



Money is cheaper than Blood

FRANCE and England gave ten to fifteen times more lives in the war than America was called on for. It cost them more in money as well.

America offered her men freely, and the way the soldiers of the "dollar-nation" fought was the bit too much that broke the enemy's spirit. They fought desperately, splendidly, reckless of wounds and death. They would not be stopped. And had the Allied armies been required to *drive* the enemy to the Rhine, the casualty lists would have been ghastly.

Money power saved those lives. The "dollar-nation" proved the might of its dollars. The enormous schedule of war preparation, the demonstration of the terrific potential power of the country, united for a common purpose, had its effect on the morale of the German people and hastened their collapse.

Industry is rapidly working back to peace production and production means money. Money—wealth—can be replaced, but lives never.

The Victory Liberty Loan represents lives saved, soldiers returned to their homes unharmed.

Everyone gives thanks that our casualties were no greater—but just how far will you go to prove it?

The Victory Liberty Loan is your chance.

How much will you take?

Victory Liberty Loan

EDITORIAL

WILSON street in Genoa has been re-named Fiume street. According to latest reports the Avenue Wilson in Paris has not yet been re-named after Colonel George Harvey, but everything is possible in this mad world.

SO, the Germans have arrived in Paris at last! They expected to be there in September 1914 and they are there in April 1919; they expected to arrive as conquering heroes; they come now to ratify an abject surrender. Against the triumphal entry into Paris of which they vaingloriously dreamed, they can set the cowardly procession of their great warships into the Scapa Flow.

ESTIMATES of the cost of producing copper are the product not only of arithmetic but of emotion: they are largely subjective and vary with the feelings of those responsible for making them. According to the 'Boston News Bureau', officials of copper-mining companies consider 15½ cents per pound a correct average today; but this represents the direct operating expense, to which must be added allowances for the depletion of orebodies and the burden of taxation, which, with depreciation, bring the total cost, it is said, close to 20 cents per pound.

GREAT COBAR shares, says the 'Financial Times' of London, "curled up" recently, collapsing from the equivalent of a dollar to the "nimble bob", which we call "two bits", the price of a good cigar. A few years ago they stood at $22. Thus ends one of the worst fiascos in British mining enterprise, and one involving the reputations of several honorable engineers, whose names we forbear to mention. Irresponsible finance and reckless share-dealing were the undoing of this mining venture, which might have made profit and reputation for all concerned, but which now leaves a soiled page in the records of mineral exploitation. The mine was over-estimated and over-capitalized from the very beginning; it was burdened with excessive promotion profits and started with an entirely inadequate working capital. All these handicaps were caused by mixing engineering with financial participation, corrupting the judgment and undermining the conscience of men from whom an unbiased opinion and a trustworthy management were expected. The various efforts to put the mine on its feet and to establish a profitable production of copper during the last five or six years have been farcical, largely because the chairman and directors were without first-hand experience in mining and were embarrassed by undue attention to the share-market. Great Cobar's story is a sad warning to the British public against mixing promotion with engineering and management with share speculation.

IF denunciation, satire, and contempt could drive a Government official back into private life, then the Postmaster General would cable his resignation to the President. Mr. Burleson has been called many bad names and has awakened the hearty dislike of many kinds of people. He has shown himself narrow, vindictive, and intolerant. It seems a pity sometimes that cabinet ministers at Washington are not accountable to Congress, because by such accounting they could be compelled to defend or explain their official acts. Mr. Burleson has challenged the publishers to make good their attacks upon his administration. They will. We shall be disappointed if he is still a member of the President's cabinet when Mr. Wilson's term expires. As Mr. Samuel Gompers says, "he must walk the plank sooner or later." Let us hope that it will be sooner.

COMPARING the markets for steel and for copper, it has been noted that whereas the price of steel during the War advanced 233% as compared with the preceding decade, that of copper gained only 127%; again, when our Government fixed prices, steel retained an advance of 111%, while copper kept only 69%; it is noteworthy also that current quotations show a drop of only 14% from the former 'fixed' price of steel, as against a drop of 42% from the copper peg; finally, that the present price of copper is 2% below the pre-war quotation, whereas that of steel is 80% above the peace normal. All of this argues that copper is unduly depressed. However, it is to be remembered that much of the buying of copper before the War, especially the purchases made by Germany, was stimulated by the expectation of hostilities. In 1913 the United States exported 826,441,000 pounds, of which 307,151,000 pounds went to Germany. Exportation was checked by the War until the Allies began to clamor for the metal at the close of 1916. In January 1917 exports totaled 51,322 long tons and during that year exportation reached its maximum, of 493,156 tons, equivalent to 1,104,893,240 pounds. By December 1918 exports had declined to 19,379 tons, and in March this year to 9735 tons only. Europe used to take 40% of our production; that 40% now would be equivalent to about as much as our entire exportation of the metal in 1913. Europe is in greater need of copper than in the year preceding the War, and would import it if only industrial equilibrium were re-established across the Atlantic. The copper market waits on the declaration of peace.

AN official statement shows that on November 11, 1918—the day of the Armistice—the various belligerents had mobilized strengths as follows: Great Britain 5,680,000, France 5,075,000, United States 3,707,000, Italy 3,420,000, making a grand total of 17,882,000 in the Allied armies. On the other side Germany had 4,500,000, Austria-Hungary 2,230,000, Bulgaria 500,000, and Turkey 400,000, making 7,630,000. The figures for our enemies, except Germany, represent conditions at the end of October, for soon after that the process of demobilization and dispersion had begun in Austria, Bulgaria, and Turkey. The British total includes the Indian army and garrisons abroad not available for fighting the enemy. By February the Allied forces had been diminished, by demobilization, to a grand total of 13,360,000, whereas the Enemy forces had dwindled to 1,125,000, of whom 820,000 were in Germany.

IN order to give its readers a story about the Tonopah mining boom, the 'Examiner' sent Mr. Peter Clark MacFarlane into Nevada, and last Sunday it published a sophomoric article on the subject. Mr. MacFarlane is, we are told, "a war correspondent and trained observer." He may be all that, but whatever he may know about war, his geology is like "the Kingdom of Heaven, which cometh not by observation." He saw "a big fault-fissure which shows itself plainly on the surface, towering 40 ft. into the air." A fault or a fissure or the combination of the two that can "tower into the air" is a phenomenon beyond the ken of the oldest prospector. It reminds us of the mine manager in Australia who wrote to his company that the ore-shoot was looking well and all that was needed was a winze on the bottom level, whereupon the secretary of the company cabled to him authorizing him to procure a first-class winze without delay! Mr. MacFarlane has been informed that the ore in the Divide mine is estimated to be worth $5,000,000, whereupon he proceeds to tell us that it is "the greatest defined orebody of silver-bearing character since the days of the Consolidated Virginia." Shades of Broken Hill and Leadville, of Huanchaca and Nipissing! has no silver bonanza been uncovered since the days of the Comstock boom, 40 years ago, or have we been dreaming? In behalf of the wild-cats clustering around the Divide mine, he suggests that one point in their favor is that "they are all located within one or two miles of what is proven to be a great mine." Somebody ought to tell him that a mile from a bonanza is about as near to wealth as a drive into a bunker is to winning the hole. It can be done, but it is rarely done. The second point in their favor is analogy with Tonopah and Goldfield, both of which, according to him, but contrary to our recollection, had only a single successful strike "at first," meaning presumably during the first year or two, for the Divide orebody was cut a year and a half ago. The analogies suggested by a war correspondent are not likely to be safe guides for those who speculate in mines. In short, the 'Examiner' is as trustworthy as usual.

Finish the Job

The American people has participated, honorably and successfully, in a stupendous task, namely, the defence of the world against an onslaught of savagery, the restoration of civilization, and the assertion of the ideals underlying democracy. We met the Prussian threat by raising three and a half millions of soldiers and by subscribing 18½ billions of dollars in four Liberty loans; our soldiers and sailors did their duty so effectively that the War was brought to a victorious end many months earlier than we had hoped; but our work is not yet finished and it behooves us to see that it is finished properly. We owe a debt to those who died for us on land and sea, not only our own fighters but those of our Allies, whom we continue to assist by money and in other ways. A fifth Liberty loan is offered for popular subscription, it is for four and a half billion dollars, in four-year notes bearing 4¾%. The opportunity to subscribe expires on May 10. It is the duty of every citizen, more particularly those unable on account of age or other disability to serve in the Army or Navy, to subscribe his quota, that is, the largest sum within his means. No more advantageous use of money is possible; the loan is safe and it offers a high rate of interest; as a short-time investment the market can offer nothing better. It is called the Victory loan because it is to be used to set the seal on the work done by our victorious Army in comradeship with the victorious armies of England, France, Belgium, and Italy. They have done their share toward winning the great War of Liberation; it is for us to discharge the debt incurred in that effort. After a battle there is much 'mopping up' to be done, says the returned soldier. There are machine-gun nests to be bombed, there are stray units to be captured, there are wounded to be gathered and removed, there are munitions to be collected, and so forth. This is a 'mopping up' loan; the money is needed to clean up our accounts and finish the job. We still have two million men under arms, and we still have to bring them home; moreover, there is the subsidy on wheat, one of our most onerous obligations, still to be met; we still have a swollen organization in Washington and elsewhere; we are still finding food and money for our Allies in the great enterprise on which we started two years ago; let us complete these remaining tasks cheerfully and thoroughly. In order to do so the Victory loan must be supported loyally. Another point suggests itself: a new enemy is lifting his ugly head, Bolshevism, the spawn of defeat. We are proud of our domestic ideals and of the principle of 'live and let live' on which this nation is founded. Let us answer this menace as we did the Prussian, and prove that we are standing whole-heartedly behind our Government—no matter what our politics—in the great work to which the United States is committed. Buy your bonds before it is too late!

Alaska's Resources

In this issue we publish an unusual article, by Mr. F. Le Roi Thurmond, who describes the accidents and hazards of a journey into Alaska for the purpose of examining a prospect on which he had been engaged to report. He had all sorts of bad weather and worse luck, but in the end he achieved the purpose of his journey and returned safe and sound. The transcript from the diary will appeal to the reader as a genuine record of the sort of experience that the prospector undergoes in the North, but it must not be supposed for a moment that every mining engineer engaged in similar work has to undergo anything so unpleasant; on the contrary, most journeys of inspection in that great region are as devoid of danger as they are rich in all the pleasures of outdoor life; indeed, we believe that the day will come when the extraordinarily vitalizing air of the 'inside' of Alaska, that is, the country beyond the coast range, will attract the valetudinarian and the invalid. For the present, it attracts the most vigorous of the race: the hunter, the fisherman, and the prospector. The mineral resources of Alaska constitute only a part of its wealth, but they are remarkable. The output during 1918 suffered for lack of labor and shipping, due to the War; in fact, since 1914 the mining activities of the entire region have been crippled by the same cause. In 1917 the value of the gold produced was $17,950,000, of which $11,140,000 came from placers and $5,910,000 came from lode mining. Last year the total output was worth only $10,000,000. The grand total yielded by the Territory since it was bought from Russia is $302,000,000, and the reader will recall the fact that the Territory, which covers 590,884 square miles, was bought for the sum of $7,200,000 in 1867. Soon after William Seward, as Secretary of State, had concluded this transaction with the Russian envoy, Edward de Stoeckl, he was asked what he considered the most important event in his career. "The purchase of Alaska," he replied, "but it will take the people a generation to find it out." It did, for not until 1900 was the varied richness of the country fully appreciated. In 1916 the output of copper, namely, 114 million pounds, was worth $28,000,000, or nearly four times the price Seward paid. In 1918 a big decrease was caused by an unfavorable combination of circumstances, the output having been only 70 million pounds, worth $17,180,000. Of this total, four mines in the Chitina district yielded 52,585,000 pounds, which suggests the importance of the Kennecott mine. Alaska responded to the call of the War and contributed a considerable tonnage of chrome and tungsten, besides some antimony, lead, and tin. In 1916 the total mineral production was worth $50,900,000. Altogether, Alaska in 32 years has yielded fifty times the price at which the Territory was bought from Russia. But that is only a part of her production. In 1916 she produced 285,000,000 pounds of marketable fish, the value of which was $26,156,560. This included 4,900,627 cases of canned salmon, worth $23,269,430. A sum of $39,569,612 has been invested in the fisheries of Alaska. It is believed that this industry is still capable of expansion and that the fishing for herring and cod can be developed much beyond its present stage. On another page we show a photograph of a salmon cannery, set amid beautiful scenery. The waste from the canneries yielded 4,413,880 pounds of fertilizer, besides 1,040,376 gallons of fish-oil. The fur trade, which first brought the white man to Alaska and was the chief industry before gold was discovered, is declining. From 1880 to 1890 the annual winning of pelts was worth $3,500,000, but in 1916 it was valued at only $1,143,601, to which the skins of the fox contributed $182,469, the lynx $259,296, and the seal $211,830. Here we may make mention of a new resource, namely, the herds of reindeer, which have increased to a total of 170,000 animals, valued at about $5,200,000. In 1892 the first reindeer were introduced to provide profitable activity for the Eskimo and the Indian. Apart from their service for haulage, the reindeer give a meat as palatable and nourishing as mutton, and their milk compares well with that of the domestic cow. The herds are said to be multiplying rapidly under the favorable conditions in which they find themselves. There remains another asset to be considered, and it is most important, namely, agriculture. Most of us are so accustomed to thinking of the North as a land of snow and ice, wolves and auroras, that it surprises us to learn how far the cultivation of grains and vegetables has been advanced. We give a couple of photographs showing the crops of wheat and cabbages grown in the vicinity of Fairbanks, which is to be the terminus of the Government railroad now being built inland from the coast at Seward. In 1917 the potato yield of Central Alaska, of which Fairbanks is the chief community, sufficed for the local consumption, in addition to the demands of the northwestern region, that is, the Seward peninsula. It is anticipated that soon Alaska will be able to produce all the vegetables required by her people, besides wheat and other grains, the growing of which is as yet in an experimental stage. Much credit is due to the experiment stations established by the Government at Rampart, Fairbanks, Sitka, Copper River, and Kodiak. Rampart is in latitude 65° 40′, just inside the Arctic Circle, yet even there it has been found possible to mature barley and oats from year to year, besides rye and wheat three years out of four. The aim of those in charge of these stations is to develop varieties of grain that will mature even in the most unfavorable season. In the Tanana and Matanuska valleys, the ripening of wheat, oats, barley, and rye is as perfect as in the Mississippi valley; moreover a most promising start has been made in the growing of sugar beets in the Matanuska district, along the line of the Government railroad. In 1918 the first flour-mill was erected at Fairbanks. It is estimated that Alaska contains 90,000 square miles available for pasturage and agriculture, that is, an area equal to that of the two States of New York and Pennsylvania. For a comparison we can quote Finland, which is bounded on the south by latitude 60° and on the north by latitude 70°; it covers an area of 148,000 square miles, or about a quarter of Alaska; and one-third of Finland is lake or marsh, yet it supports a population of 3,000,000, which is about sixty times that of Alaska. What the Territory needs is population and transport—in other words, men and markets. Of the 5000 men that were enlisted in the Army and Navy fully 80% will return to Alaska, and we shall be surprised if the youth of the States does not hear 'the call of the wild' and go to the North now that the War is over. The building of the Government railroad promises some of the facilities of transport that the country needs for the distribution and exportation of its products, but the restoration of the shipping is even more important at this time. Coastal trade will be stimulated by the successful exploitation of the coal deposits of south-eastern Alaska, in the Bering River and Matanuska districts especially. We hope that the Chambers of Commerce at Portland, Seattle, and San Francisco will awaken to the importance of the subject and make a renewed effort to initiate activity in that direction. Alaska is a great American asset and it deserves the most friendly attention of our people, and of Congress.

The Italian Impasse

Whatever may be the final settlement of Italy's insistent demand for the possession of Fiume, it is evident that the dispute affords a premature test of the sincerity of the efforts to organize a league of nations for the settlement of international differences. It is a fact that the secret arrangement between France, England, and Italy, known as the Treaty of London, signed just before Italy became a militant Ally, did not give Fiume to Italy but to Croatia, at that time a province of Austria and now a part of the consolidated Jugo-Slavia, which includes all the Slavic elements in the Balkan-Adriatic area. If Italy stands by the pact of London, she must not pick the clauses that suit her; she must abide by all of them, and that would leave her without Fiume. To give possession of this port to Italy would be unjust to the new republic on the eastern shore of the Adriatic, for without it the Jugo-Slavs would have no gate to the sea. Italy has regained Trieste, which is near-by, and she has Venice, at the head of the Adriatic. That the population of Fiume is largely Italian may be true, but Alexandria and Smyrna are largely Greek in population, so likewise many other ports are populated by those of a race alien to their governments; it would be wholly impracticable to re-distribute sovereignty on such a basis without doing wrong to the peoples using these ports as their front doors. In adjusting conflicting claims it may be necessary to hurt the feelings or even to trespass on the rights of one of the opposing claimants in the effort to settle a difficulty and establish a stable government. If Italy refuses to play the game and prefers to sulk by herself at this great juncture, she will do herself grave discredit. The ardent desire of the Italian populace for this outpost of Italian commerce is not enough to upset the great plans to which her leaders have committed themselves at Paris. France does not receive all she wants, yet her delegates do not leave the council chamber in protest. The crisis has given President Wilson a great opportunity and he has risen to it superbly. We confess that many of his utterances leave us cold, but his statement, issued at Paris on April 23, was an appeal commanding the approval and sympathy of every good citizen, not only in this country but wherever men dream and hope for a peaceful adjustment of international affairs. In refusing to recognize the secret treaties made before the United States became a partner in the War and in emphasizing the impracticability of carrying out these secret agreements in the face of changed circumstances, more particularly the creation of a number of independent States, he will be justified by the good sense of mankind; moreover, his insistence on the principles upon which the Armistice was signed and to which Italy is a consenting party, the principles for which he has made himself the chief spokesman, is entirely logical, for without adherence to this definite basis of adjustment it is impossible to fulfill the purpose for which we and our Allies have fought. Italy is no longer threatened by the Austrian navy, for Austria-Hungary no longer exists, and the League of Nations will place such limitation on armaments as to render aggression impossible from the eastern side of the Adriatic. Italy, as the President says, has become a trustee for a new order of things, and it behooves her to play her part honorably, not to withdraw at the first suggestion of a sacrifice of a small part of her territorial ambitions. Without her Allies she would have been crushed and starved; if fortunately she chose to break away from the Central Powers and to throw in her lot with the Allies, she must join with them now in subordinating one of her many desires to the fulfillment of the great object for which the Allies fought, or else suffer the stigma of having played a supremely selfish part. The War has done great things for Italy; it has unified her people; it has restored to her the old frontiers; it has smashed her dangerous neighbors; it has given new warmth to her national life. The action of her delegates at this time is calamitous if it should be sustained by her Parliament, for it threatens to disrupt the League of Nations on the very eve of its formation; if the members of the league are going to refuse to play ball every time the referee gives an adverse decision it will be useless to continue the game. We hope Italy will re-consider her action. As the President has said, "it is within her choice to be surrounded by friends; to exhibit to the newly liberated peoples across the Adriatic that noblest quality of greatness, magnanimity, friendly generosity, the preference of justice over interest." In other words, to play the game like a sportsman.

The Internal Corrosion of Cables

By WM. FLEET ROBERTSON

This paper owes its origin to a fatal accident that occurred in the Protection Island shaft of the Canadian Western Fuel Co.'s colliery at Nanaimo, B. C., on September 10, 1918. By this accident 16 men were instantly killed through the hoisting-rope breaking, thus dropping the cage to the bottom of the shaft. A coroner's inquest was held at Nanaimo and a governmental investigation ordered to determine the cause of the failure of the rope. I was called upon to make this investigation.

To give an intelligible account of the accident it will be necessary to describe in brief outline the colliery itself:

The Nanaimo colliery was opened up about 1853 by the Vancouver Coal Co., an English corporation. Two circular shafts were sunk within a few feet of the shore of Nanaimo harbor to cut the Douglas seam of coal at a depth of about 603 ft. This shaft today is known as the No. 1 or Esplanade shaft.

The coal was found to be dipping to the east, that is, under the harbor at a low angle, about 10°. At the entrance to the harbor is an island, Protection island, under which the coal beds extend, and there later a shaft was sunk, to cut the Esplanade shaft seam at a depth of about 630 ft. This shaft was fully equipped and for years hoisted coal. Eventually the underground workings of the Esplanade shaft and the Protection Island shaft were connected, the direct distance between the two shafts being about 1½ miles.

For economic reasons the hoisting of coal was discontinued at the Protection Island shaft, the entire output being raised through the Esplanade shaft. The former shaft ceased to be used for hoisting in 1904 but it continued in use for the lowering and raising of men working in that part of the now extensive workings. A small amount of coal continued to be raised here but only enough to generate steam for a fan, air-compressor, pump, and the hoisting-engine, the records showing that this amounted to less than 1000 tons per month, in two cages, or about 500 tons per rope.

At the Esplanade shaft there was hoisted from 15,000 to 20,000 tons of coal per month on each rope, together with a greater number of men than at the Protection Island shaft and all the mine-timber, etc.

The hoisting-plant at Protection island was steam-driven, the hoisting-drum being cylindrical, 10 ft. diam., and the head-sheave likewise 10 ft. in diameter. The hoisting-cable was 1¾ inches in diameter, Lang's lay of crucible steel wires, 6 strands of 16 wires each around a hemp centre about ¾ in. diameter.

The shaft was vertical, each compartment fitted with four wooden guides of 4¾ by 4¾ in. lumber. The cage was provided with four pairs of safety clutches, a pair on each guide, brought into operation by four pairs of tension spiral springs, three inches in diameter of ⅝-in. round steel. Each spring when new, as shown by subsequent tests, had a safe elongation within the elastic limit of 30% when it had a pull of 1200 pounds.

Why these safety-clutches failed to work is an unanswered question, but they never touched the guides. Possibly it was on account of its being a descending trip, and, as the rope broke 179 ft. above the cage, the lash of the rope may have kept the clutches out of action.

The shaft was used as an intake-air shaft, being housed over the top and attached to a forcing fan, the air being used as an auxiliary to the general supply. It was a very wet shaft, but the water falling into it was free from acid, being somewhat alkaline as shown herewith:

	Gr. per gal.
Calcium sulphate	14
Calcium chloride	10.3
Magnesium chloride	190
Alkali chlorides (soda and potash)	1262

The rope had been installed on March 6, 1915; it broke on September 10, 1918; so that the period of service was 1282 days or almost exactly 3½ years. It broke 179 ft. above its point of attachment to the cage, and, as nearly as can be ascertained, the break occurred about the time the point of break had just passed over the head-sheave on a descending trip.

The load on the rope was

	Lb.
Weight of car	4357
Weight of 179 ft. of rope	540
Weight of 16 men	2720
	7617 lb. = say 4 tons

The evidence was that the cables were examined almost daily by a man appointed for the purpose, but his examination consisted of allowing the cable to pass slowly through his gloved hand, or holding a piece of stick against the moving cable, a practice that might detect broken or projecting wire-ends, but gave no indication as to internal corrosion of the cable.

The method of lubrication consisted of frequently applying cold ordinary black lubricating oil on waste or burlap to the cold cable, but the oil evidently did not penetrate the cable at all.

Three coils of the cable, of about 100 ft. each, were taken to Montreal and tested in the Physical Testing Laboratory of McGill University for tensile strength under the supervision of Professor H. M. Mackay, with S. D. McNab in charge of the laboratory. One coil of the cable was from the hoisting-drum and had always been under shelter and not exposed to the shaft conditions. This part of the cable stood up to a strain of 80 tons, which was 89.35% of the aggregate strength of the individual wires tested separately and was above the guarantee of the makers, T. & W. Smith, of Newcastle-on-Tyne, England, of 78 tons for the new rope, and represented a tensile strength of the steel wires equivalent to 208,000 lb. per square inch. The test indicated a cable well made and of first class material.

The accompanying sketch shows the positions from which test-pieces were taken and their respective breaking-strengths.

These tests showed conclusively that deterioration of the rope was 'spotty'; it followed no order of progression and apparently was unaccounted for by any local conditions in the shaft. They also illustrated the futility of putting any reliance upon a test for tensile strength made on a piece of cable cut from the portion next to the cage.

A close examination of the external surface of the cable failed to show any wire-ends broken, worn, or projecting, the usual danger-signals when the cable is failing from wear. The wear or the rusting of the externally visible wires was not such as to cause apprehension. Micro-photographs by Dr. Stansfield showed conclusively that no crystallization had taken place in the steel of the cable.

An examination of the fractured ends of the test-pieces settled so conclusively that the failure of the cable was entirely due to the corrosion of the internal wires that further search was unnecessary. The wires externally exposed had been subjected to frequent applications of an oily rag, which supplied a sufficiently superficial lubrication to protect the wires externally, but the interior of the cable had evidently been absolutely devoid of oil, or other protective agent, and the wires internally were badly rusted, many of them corroded to threads and others completely eaten through, in fact, in Test No. 5, in opening up the ends for attachment to the grip, 32 wires were picked out, completely severed.

It became evident that the strength surviving in the cable was approximately in proportion to the cross-sectional area of the wires remaining unoxidized, the quality of the steel remaining about the same as in the unrusted wires. This was so obvious that a visual examination of the broomed out end of a test-piece enabled a close estimate to be made in advance as to what the breaking strength of the test would be. Conversely, the breaking-strength of the portions of the cable was a fair index of the amount of oxidation that had taken place in these respective portions.

The results of these tests have been to emphasize most strongly the fact that the external conditions of a cable is no criterion as to its remaining strength in cases similar to the one described. Of course, if a cable is subjected to heavy external wear it will deteriorate from that cause, possibly before internal corrosion could have become serious, but such deterioration, being visible, ceases to be dangerous. In the case under review, however, the external appearance of the cable would lead any rope inspector, such as is usually employed, to believe the cable to be perfectly safe, whereas it was a "whited sepulchre" and rotten inside.

That this case has a much wider application was brought to my notice by a piece of 1¼-in. cable from a Sudbury mine that came into the McGill laboratory to be tested during my stay there. This cable, from all outward appearances, was practically as good as new, but the tensile test and the broken ends showed it to be internally rotted with rust.

A subsequent critical examination of the interior of other cables made by the British Columbian Mines Inspection staff further indicates the disease to be only too prevalent. To my mind, the cause is the total lack of internal lubrication and the remedy must be continued — internal lubrication with suitable oils—beginning when the cable is new and renewed at short intervals; for, if the rust is allowed to start it is difficult if not impossible to stop it.

As to how this internal lubrication can best be effected is an open question, but I am convinced that, to be effective, the cable must be immersed in oil for an appreciable time and that both the oil and the rope must be heated above the boiling-point of water, and also that the immersion of the cable in the oil must be repeated at frequent intervals. Ben B. Thayer of the Anaconda Copper Mining Co. informed me that it was the practice of his company at Butte to pass the cables periodically through a bath of oil contained in a long trough heated with live steam. A mine manager to whom I suggested this, remarked, "If this is necessary, why do not the makers of the cable tell us to do it?" It may be news to the makers that they are supposed to supply such instructions with their commodities, but they might well take the hint.

Observation of the fact that the pieces of cables tested had tensile strengths approximately proportional to the sectional area of the wires remaining intact and unoxidized, brought back to me one of the few electrical principles remaining in my mind of the instruction I received many years ago at McGill, namely, that the conductivity of a wire is directly proportional to its cross-sectional area. This suggested the thought that if we could test the conductivity of any suspected part of a cable, this ratio would give us, approximately, the ratio between the tensile strength of the new and the suspected part of the cable.

To test this theory I appealed to W. D. Fowler of the electrical department of McGill University. I had with me a piece of the unused cable and a length of 65 ft. of the deteriorated cable, which extended between test-piece No. 3, with a tensile strength of 25 tons, and test-piece No. 4, with a tensile strength of 55 tons. Mr. Fowler tested the unused cable and also tested the 65 ft. of cable in sections of five feet each for electrical resistance, and his report is given in graphic form in the accompanying sketch showing the electrical resistance found in the successive 5-ft. sections of the 65 ft. of defective cable.

These tests were only approximate, as the method of attachment of the wires to the cable was imperfect, but they were close enough to show the theory to be substantially correct.

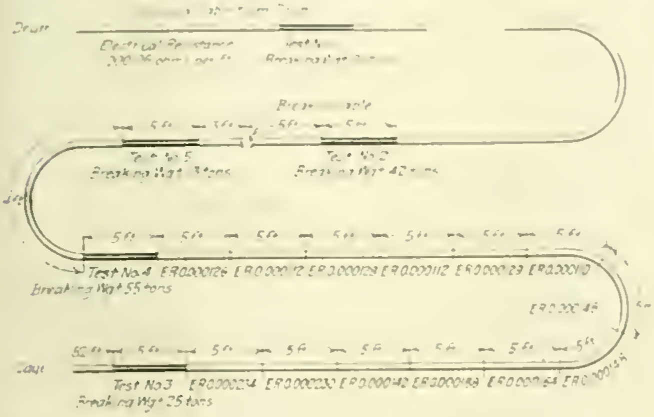
The tests showed the electrical resistance to be as follows:

No.		Resistance in ohms per foot
1	Unused cable	0.000108
2	Defective cable in 5-ft. lengths immediately adjoining test No. 4 having a tensile strength of 55 tons	*0.000120
3	Defective cable in 5-ft. lengths immediately adjoining test No. 3, which had a tensile strength of 25 tons	†0.000234

*About 10% greater resistance than No. 1, the unused cable.
†About 120% greater resistance than No. 1, the unused cable.

These figures, while admittedly inconclusive, show such marked variations as to be sufficiently serviceable for detecting any dangerous internal destruction in a cable.

The principle has a wide field of application to the stand-in cables of rope-tramways, suspension bridges, etc., and quite possibly it may be found applicable to test the amount of corrosion that has taken place in iron or steel members used in reinforced concrete structures where such are concealed from observation. That a simple and rapid method can be devised to test cables seems probable from observing the rapidity with which a man tests the condition of connections at the rail-joints on the electric street-railways with a small galvanometer wound in one direction for resistance in a given length of rail including joint, when, if the joint is as good as the rail, the galvanometer stands at zero. An enlargement of this appliance would be applicable for testing cables.



TEST OF ROPE FOR ELECTRICAL RESISTANCE

A BOILER that is to be out of commission for some time, say two weeks or longer, should be prepared for laying-up as follows: Shell or drums are opened, thoroughly cleaned, and all scale, dirt, or other foreign material removed. Plates should be wire-brushed where accessible. Then manhole and handhole-plates should be replaced firmly, the air-cock on top of boiler opened, and the boiler filled full of water, leaving no air-pockets in shell or drums. The air-cock should then be closed. This will exclude all air, and prevent rusting or corrosion of the interior of the boiler. In freezing weather this plan cannot be carried out, so another method is as follows: After the interior has been cleaned, and the boiler ready for closing up, metal pans or trays, as large as can be passed through the manhole-plates, are placed inside the boiler. The pans are filled two-thirds full of unslaked lime, then the manhole-plates are secured, main steam, auxiliary steam, feed and blow-off stops are firmly closed, to exclude all moisture, the various lines being broken, and blank flanges put on if necessary. The lime will absorb all moisture from the air, and this will again prevent internal deterioration.—L. D. Miller, formerly with California Industrial Accident Commission, now in the Navy.

Inspiration Mill Statistics for 1918

The annual report contains the following data:

Ore milled, dry tons	5,110,101
Average per day of milling operations, tons	14,172
Number of sections running	14.8
Average rate per section, tons	956
Screen analysis of mill-feed to concentrating machine (on 48 mesh), per cent	3.4
Assay of mill-feed, per cent copper	1.361
Oxide copper in mill feed, per cent	0.294
Assay of general mill tailing, per cent	0.380
Oxide copper in general mill tailing, per cent	0.253
Smelter assay of concentrates produced, per cent	30.398
Assay of flotation concentrates, per cent	35.26
Assay of table concentrates, per cent	16.31
Moisture in general concentrates, per cent	20.16
Ratio of concentration	32.5
Recovery:	
Recovery of copper in milling (smelter assays) calculated from assays only, per cent	72.99
Assays and weights of concentrates and ore, per cent	72.27
Assay and weights of concentrates and tailings, per cent	72.82
Assays and weights of ore and tailings, per cent	73.02
Recovery of copper sulphide in ore, per cent	88.51
Net water used per ton of ore (310 gal.), tons	1.29
Power used per ton of ore milled, kw. hour:	
Coarse crushing	0.45
Fine grinding and concentrating	10.12
Blowers for flotation air	2.79
Filtering and reclaiming water	2.32
Lighting	0.12
Total	15.80
Steel ball consumption in fine grinding per ton of ore milled, pounds	1.82
Flotation oil consumption per ton of ore milled, pounds:	
Coal-tar	1.20
Sundry oils	0.15
Total	1.35

Tungsten Losses in Making Ferro-Tungsten

An interesting fact brought out by the U. S. Bureau of Mines questionnaire sent to tungsten manufactures, and compiled for the last six months of 1918, is that the average loss in tungsten, in the making of ferro-tungsten is about 14%. This figure is, however, doubtless considerably too low, as correspondence has brought out the fact that the tendency was to give the lowest figures realized rather than true averages; hence it is believed that about 25% would be nearer the true average of loss. These losses are largely mechanical, though in the chemical processes there is a loss due to incomplete reactions, incomplete precipitation, etc. The questionnaires for 1918 showed that in a monthly production of about a million pounds of contained tungsten, approximately 22% was tungsten powder, and the remainder was contained in ferro-tungsten.—H. C. Morris in Monthly Report of U. S. Bureau of Mines.

The German Metal Octopus—II

ISSUED BY THE ALIEN PROPERTY CUSTODIAN

THE GERMAN METAL TRIUMVIRATE IN THE UNITED STATES. At the outbreak of the European war each member of this triumvirate had a branch of its business in the United States. The Metallgesellschaft had the American Metal Co., Aron Hirsch & Sohn had L. Vogelstein & Co., and Beer, Sondheimer & Co. had a branch under its own name. All these branches were centred in New York City, and all developed vast and extensive interests in the United States, Mexico, and South America, including the control of mines, smelters, and refineries. We now proceed to point out somewhat in detail the ramifications of these three German-owned and German-controlled companies.

(a) *American Metal Co. (Ltd.).* In or about the year 1887 the Metallgesellschaft sent to the United States two of its representatives, to wit, Jacob Langeloth and Berthold Hochschild, to establish a branch of the Metallgesellschaft's business. At that time the present banking firm of Ladenburg, Thalmann & Co. were doing a metal business and had connections with the Metallgesellschaft. An arrangement was made resulting in the organization of a corporation called the American Metal Co., under the laws of the State of New York, with a capital of $200,000, divided into 2000 shares, to which corporation Ladenburg, Thalmann & Co. turned over their metal department. The stock of the corporation was issued as follows:

	Shares
Metallgesellschaft	600
Henry R. Merton & Co.	595
Ladenburg Thalmann & Co.	710

The balance of the stock was allotted to various officers. It will be noted that from the very organization of the American Metal Co. the stock control thereof was in the hands of Henry R. Merton & Co. and the Metallgesellschaft. These German interests continued to retain that control through all the years of the development of the American Metal Co., and had the control at the outbreak of the European war. The capital stock of the American Metal Co. was increased from time to time, as follows:

1891, from $ 200,000 to $ 300,000
1897, from 300,000 to 600,000
1899, from 600,000 to 1,000,000
1902, from 1,000,000 to 1,500,000
1904, from 1,500,000 to 2,000,000
1906, from 2,000,000 to 3,000,000
1909, from 3,000,000 to 3,500,000
1917, from 3,500,000 to 7,000,000

That the Metallgesellschaft and Henry R. Merton & Co. at all times controlled more than a majority of the stock of the American Metal Co. will appear from the following tabulation:

Year	Total shares out	Metallgesellschaft and Henry R. Merton & Co. held
1891	3,000	1,892
1897	6,000	3,789
1899	10,000	5,795
1902	15,000	8,695
1904	20,000	11,460
1906	30,000	17,840
1909	35,000	23,312
1917	70,000	16,624

From the time of its organization and up to the outbreak of the European war the American Metal Co. did its business on the European continent through the Metallgesellschaft and in Great Britain through Henry R. Merton & Co. No sales were made by the American Metal Co. in Europe except through these two concerns. Prior to the European war it was the custom of the company to receive cable quotations for various metals daily, both from the Metallgesellschaft and from Merton & Co., and, based upon the advices thus received, daily they planned their business for the day.

At first the American Metal Co. confined its business to trading in metals both for export and import as well as in the domestic market, but, as will presently appear, it soon acquired interests in smelters and refineries, and became an extensive owner of mines in the United States, Mexico, and South America. Through the ownership of stock in other companies, it has gained the control of the output of copper, zinc, and lead mines, and it operates smelters in the United States and Mexico, producing copper, zinc, and lead. Annexed hereto is a chart prepared by the officers of the American Metal Co., showing in three groups (1) companies owned or controlled and operated by the American Metal Co., (2) companies in which American Metal Co. has a part-ownership and a board representation and with which it has important contractual relations, and (3) companies in which the American Metal Co. owns shares and bonds as investments.

In amplification of the chart, the company has furnished the following particulars regarding its most important subsidiaries:

Name	Capital stock	Per cent owned
In the United States		
American Zinc & Chemical Co.	$2,500,000	100
Bartlesville Zinc Co.	500,000	100
American Metal Transport Co.	100,000	100
Metallurgical Co. of America	100,000	100
Langeloth Coal Co.	100,000	100
Langeloth Mercantile Co.	5,000	100
Langeloth Townsite Co.	5,000	100
Chanute Spelter Co.	5,000	100
Clarksburg Clinkering Co.	5,000	100
Ohio & Colorado Smelting & Refining Co.	3,000,000	[illegible]
In South America and Mexico		
The South American Metal Co.	[illegible]	100
Compania de Minerales y Metales	1,250,000	97.7

The *American Zinc & Chemical Co.* owns a zinc smelting plant with a capacity for the treatment of from 7000 to 8000 tons of zinc ores per month, and the production of 3000 to 4000 tons of spelter. It also owns a sulphuric acid plant with a capacity of 7000 to 8000 tons of sulphuric acid monthly. This property represents an investment of over $1,000,000, and may be divided into the following subheads:

1. Zinc smelting plant. This plant consists of eight blocks of two furnaces each, each block containing 912 retorts, making a total retort capacity of 7296. Each block is equipped with waste-heat boilers; the furnaces are fired by Woods gas-producers, one producer to each block. The smelting plant has complete accessories, such as power-house, two steam-turbine generator units of 2000 kw. each, up-to-date machine-shop, carpenter-shop, and pottery plant.

2. Sulphuric acid works. This department has a chamber-capacity of from 8000 to 8500 tons of 60° B. sulphuric acid monthly, and also has a contacting plant for the conversion of about 3500 tons of 60° acid into 66° acid. The raw material used in the manufacture of sulphuric acid is zinc sulphide ore, for the roasting of which four Hegeler kilns with necessary accessories are available. These kilns have a capacity of about 5000 tons of ore monthly, which would correspond to approximately 5000 tons of 60° acid. For the handling of the crude ore the works are equipped with modern drying and sampling plants, and storage-bins with a capacity of about 18,000 tons, with overhead cranes. The sulphuric acid plant is one of the most modern in the country, and can be expanded for the production of other acid-products whenever desired.

3. Coal mine. The company owns coal-mining rights over an area of 2450 acres of the Pittsburgh and Rooster veins. It was estimated that there was a coal reserve in this tract of over 18,000,000 tons, from which only a little over 1,000,000 tons have been mined. Of the above acreage the company owns surface and coal-mining rights on 723 acres and coal-mining rights on the remainder. The mine is equipped to produce about 50,000 tons of coal monthly. The coal mine is subject to a mortgage of $476,000, against which there was on deposit with the Colonial Trust Co., of Pittsburgh, on December 31, 1918, a sinking-fund credit of $23,905.93.

4. The Langeloth Townsite Co. was incorporated for the purpose of taking over a block of real estate adjacent to the works of the American Zinc & Chemical Co., embracing about 400 acres, with the idea of developing it into a modern industrial town. The town-site has nearly 400 houses completed, some of which have been sold and others leased to the workmen on easy payments. Modern sewerage, complete sanitary water-supply, first-class schools, and playgrounds have been provided.

5. For the convenience of the workmen, the company operates a general store under the name of the Langeloth Mercantile Co. The store-building is owned by the American Zinc & Chemical Co., which leases it to the Mercantile Co. The latter company sells from $300 to $400 worth of merchandise per day, on which it attempts to make a profit only sufficient to cover operating expenses.

6. By-products plants. The company owns and operates:

(a) A zinc-oxide plant with a capacity of about 500 tons of zinc oxide monthly.

(b) A zinc-dust plant which produces from 150 to 200 tons of zinc dust monthly.

(c) A zinc-sulphate plant which has been running only intermittently, owing to lack of demand for this material.

Bartlesville Zinc Co. owns and operates two zinc-smelting plants at Bartlesville and one at Blackwell, Oklahoma, representing a total investment of $2,500,000. One of the Bartlesville plants was formerly owned by the Lanyon Starr Smelting Co. (which latter company has now been consolidated with the Bartlesville Zinc Co.). This plant has six furnaces of 576 retorts each, making a total retort-capacity of 3456. The other Bartlesville plant has nine furnaces of 576 retorts each, making a total retort-capacity of 5184; it also has two re-distilling blocks on which high-grade spelter is made.

The Blackwell plant has 12 furnaces of 800 retorts each, a total retort capacity of 9600. At Bartlesville there is also a zinc-oxide plant, which produces about 350 tons of oxide monthly; also a zinc-dust plant, which produces from 100 to 150 tons monthly. Both Bartlesville and Blackwell smelters are equipped with clinkering-plants in which the residue-carrying precious metals are treated to make them available for blast-furnace treatment for the recovery of their remaining metal-values. This clinkering process is covered by patents owned by the American Metal Co. The total capacity of the Bartlesville, Lanyon Starr, and Blackwell plants in normal times is approximately 14,000 tons of ore per month, from which 5000 to 6000 tons of spelter are produced.

Clarksburg Clinkering Co. owns and operates a clinkering-plant at Bridgeport, West Virginia, under the patents mentioned above, for the treatment of value-bearing residues.

Chanute Spelter Co. owns in fee 628 acres and holds under lease about 17,000 acres of land, mostly in Cherokee county, Kansas, adjacent to the Joplin district of Missouri. This acreage was selected after careful study of the geological conditions governing the ore occurrences in this district, and the Metal Co. has invested, through the Chanute Spelter Co., for the acquisition of fees and leases, as well as in development work, approximately $500,000. The leases provide for the payment of royalties varying from 5 to 12½% on the sales-value of the ore produced. It is the expectation of the company that during 1919 they will draw at least a portion of their zinc-ore requirements from their holdings in this district, and that the ore production from these properties will steadily increase in the future.

Metallurgical Co. of America was incorporated for the purpose of carrying on experiments in metallurgy, perfecting and improving metallurgical processes, and holding all metallurgical patents in which the American Metal Co. was interested. A few years ago all of its properties, patents, etc., were transferred to the American Metal Co. and the Metallurgical Co. became merely a department of the parent company. Today it owns nothing except $100,000 in cash, which is the equivalent of its outstanding capital stock.

American Metal Transport Co. was incorporated for the purpose of handling all the shipping of the parent corporation and its subsidiaries, primarily between the United States and South America. It is also engaged in the operation of steamers under charter and has likewise been employed by the United States Shipping Board in the operation of steamers owned or leased by the Government.

In addition to the foregoing properties in the United States, of which the American Metal Co. owns 100%, it has substantial stock interests in a number of other corporations in the United States and elsewhere, of which the following merit separate description:

Ohio & Colorado Smelting & Refining Co., of which the American Metal Co. owns 38,557 shares out of 50,000 shares issued. This company owns a lead smelter at Salida, Colorado, with a smelting capacity of about 12,000 tons of ore per month, from which it produces from 1000 to 1500 tons of lead bullion. The smelting company is indebted to the metal company for over $1,000,000 and is not considered a valuable investment.

Balbach Smelting & Refining Co., of which the American Metal Co. owns 1300 preferred shares and 1302 common, representing approximately a one-third interest, with a book value of $225,600. This company operates a copper and lead smelting and refining plant at Newark, New Jersey, with a capacity for the treatment and refining of about 4000 tons of lead and approximately 4,000,000 lb. of copper monthly. It also owns real estate in the city of Newark and on Newark Bay valued at approximately $500,000.

Nichols Copper Co. The American Metal Co. owns 1400 preferred and 9805 common shares in this company; also 150 bonds. The share interest is about 14%. The Nichols Copper Co. owns and operates a copper refinery at Laurel Hill, Long Island, with a capacity for the treatment of about 40,000,000 lb. of copper monthly. The American Metal Co. carries the common shares on its books at $100 and the preferred shares and the bonds at par, making a total investment of $1,570,500.

The South American Metal Co. This company was organized in June 1917, for the purpose of conducting a general trading business in South America, especially in Chile, in minerals, coal, coke, and wholesale merchandise generally. Although up to the present time, owing to the diversion of shipping tonnage to business most essential to the conduct of the War, trade between South America and the United States has been substantially reduced, the company has been carrying on a fairly active business, chiefly in coal and coke

The South American Metal Co. controls the Guayacan copper smelter at Guayacan, in the Province of Coquimbo, Chile, which was incorporated in 1917 as the Fundicion de Guayacan, with 150,000 shares at £1 each, of which it (as agent of the American Metal Co.) owns 120,750 shares, the balance being owned by Chilean citizens. The smelter represents an investment of over $400,000, and includes in its holdings extensive waterfronts on the harbor of Guayacan as well as several small tributary mines, together with barges, boats, and miscellaneous smelter-equipment. The smelter is capable of producing from 350 to 500 tons of copper matte per month. It was shut-down in 1917 on account of war conditions, and has not yet re-commenced operations.

The South American Metal Co. also supervises mining explorations which the American Metal Co. carries on in South America.

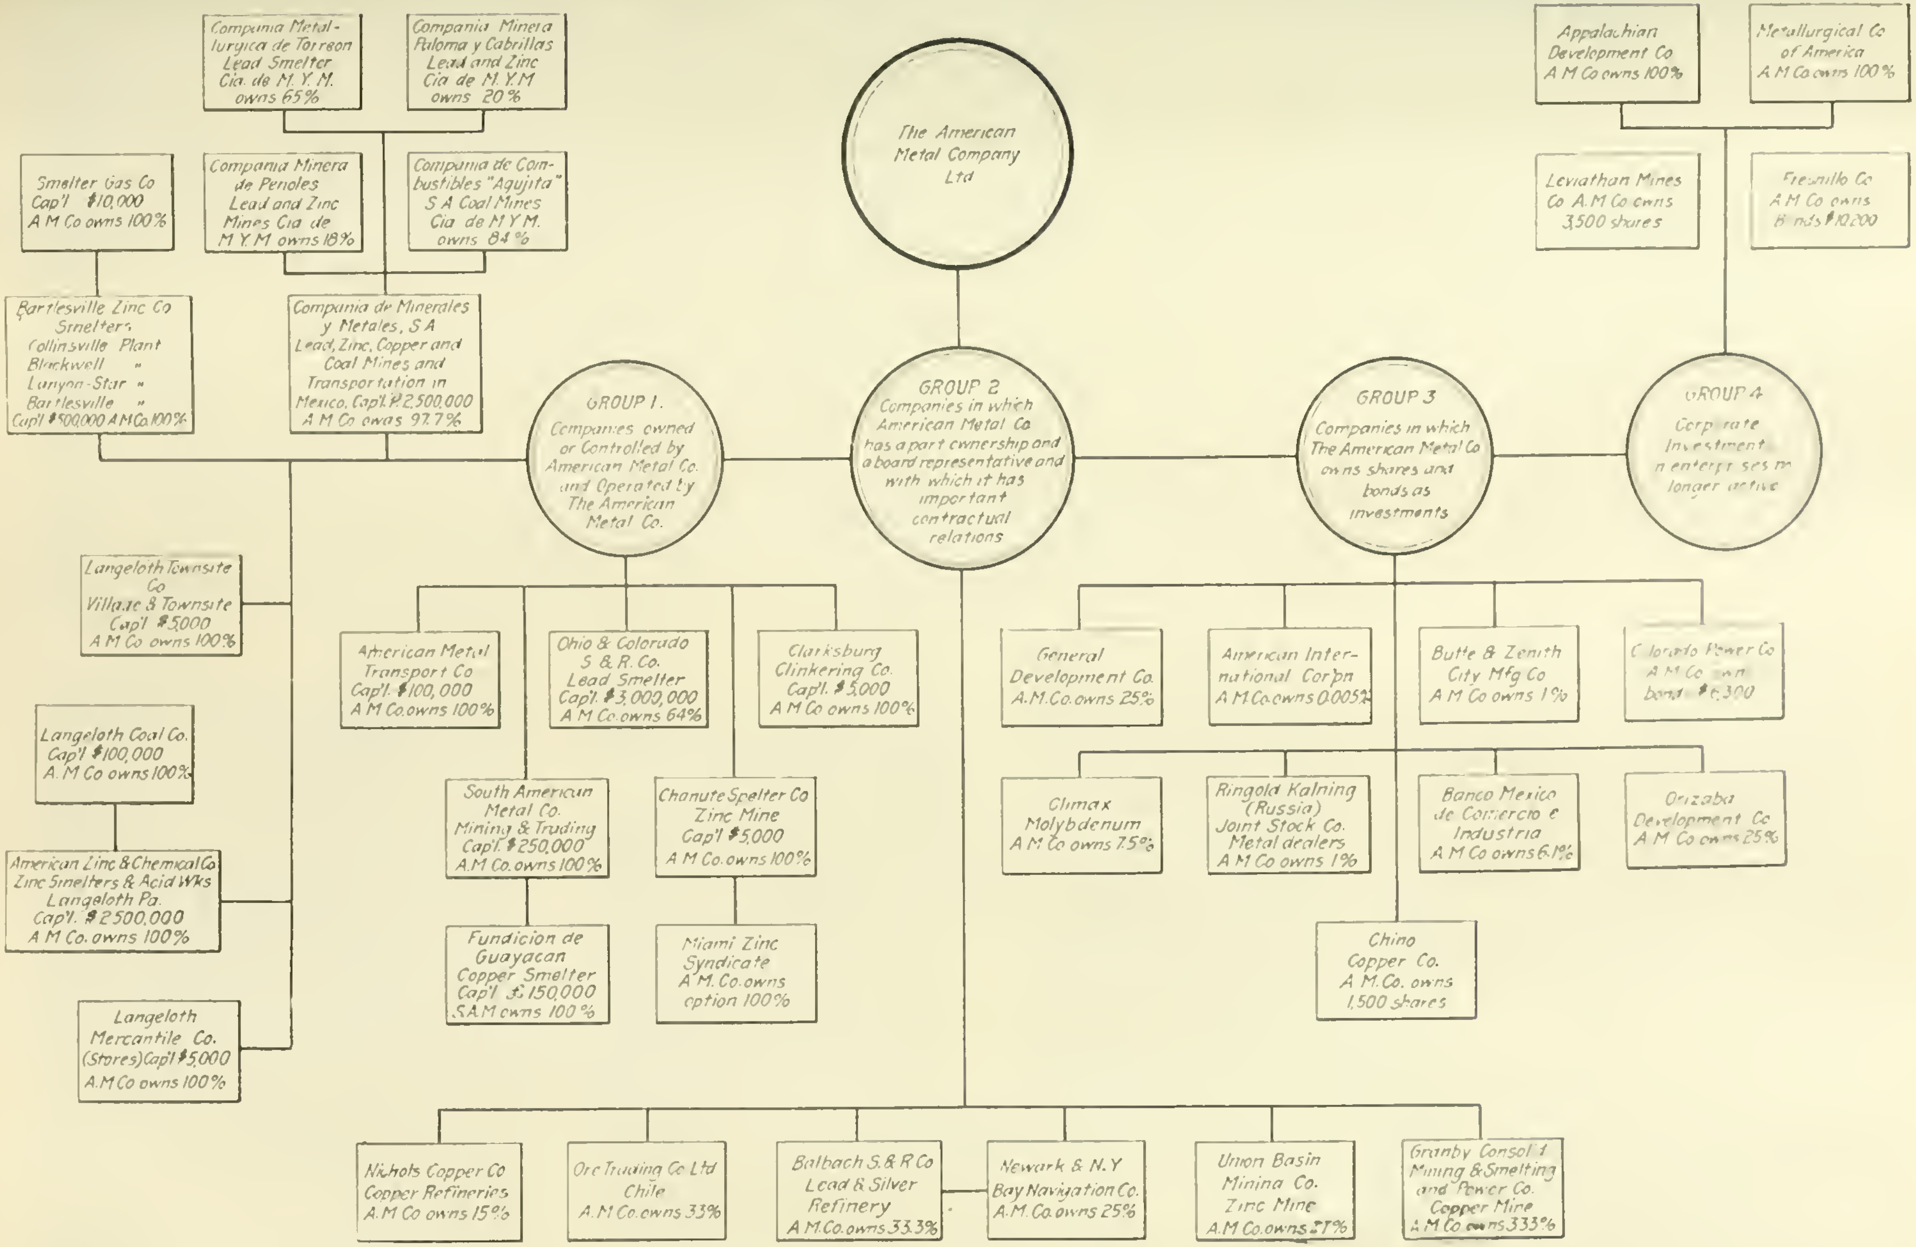
MEXICAN HOLDINGS. The American Metal Co. also owns extensive properties in Mexico; these are handled through a Mexican holding corporation known as the Compania de Minerales y Metales. The latter is capitalized at 25,000 shares of the par value of ₱100 each, of which the American Metal Co. owns 24,423 shares. The original capital of the Minerales Co. was 1250 shares of the par value of ₱100 each, of which the Metal Co. owned originally 673 shares, the remaining 577 shares being owned by the Metallgesellschaft of Frankfurt, Germany. In 1917, finding itself in need of additional capital, the Minerales Co. increased its capitalization by the addition of 23,750 additional shares, which were offered pro rata to the stockholders, subject to subscription within 30 days, shares not subscribed by any stockholder to be offered to those subscribing for the remainder. The notices of the proposed increase were published as required by law in Mexico, and the American Metal Co. duly subscribed for its pro rata of the new shares, amounting to 12,887. The German shareholders failed to subscribe for their pro rata, namely, 10,863, and those were subsequently offered to and purchased by the Metal Co., thereby increasing its holdings of Minerales shares to 24,423, leaving the German interest 577 shares, representing their original holdings. Of these, 565 shares are in the possession of the Alien Property Custodian and will be offered for sale separately. The remaining 15 shares are in possession of the German stockholders or their agents in Mexico.

Compania de Minerales y Metales, S. A., owns outright the following properties:

1. Smelter and mines at Guadalupe, in Nuevo Leon
2. Mines and smelter at Cerralvo, in Nuevo Leon.
3. Providencia mines, in Zacatecas.
4. Mines at Guanacevi, in Durango.
5 Mining leases at Santa Eulalia, in Chihuahua
6. Oil leases in the State of Vera Cruz.
7. Railroad equipment and machine shops.
8. Real estate.

Compania de Minerales y Metales has the management or control of the following companies:

9. Agujita coal mines in Coahuila.
10. Fuel Sales Co.
11. Torreon smelter in Coahuila.
12. Parrena Mining Co., in Coahuila
13 Paloma mines, in Coahuila



Compania Metalurgica de Torreon Lead Smelter Cia. de M. Y. M. owns 65%

THE AMERICAN METAL COMPANY AND ITS CONNECTIONS

14. Penoles mines, in Durango.
15. Smelter and refinery at Monterrey

1. Near Guadalupe the company owns mining-lands embracing 2270 acres, from which are produced lead and zinc ores that are sent over a narrow-gauge railway of 18 miles to the treatment plant at Guadalupe. This plant has one blast-furnace with a smelting capacity for 75,000 tons of lead ores, annually, from which may be produced 7000 to 8000 tons of bullion. There is also a calcining-plant at Guadalupe for the treatment of zinc-carbonate ores, capable of handling 7000 tons per month. This calcining-plant is used for the treatment not only of the ores from the mines near Guadalupe, but also from the company's other mines and such as may be purchased from outside parties. At Guadalupe there is also a modern power-plant, offices, workmen's houses, schools, hospitals, and other miscellaneous equipment for the operation of a modern smelting unit.

2. *Cerralvo.* This unit also consists of a mine and smelter. The mine covers 790 acres and produces a high-grade silver-lead ore which is treated at the concentrator and subsequently shipped out or treated at the smelter at Cerralvo. The mine is producing 1200 tons of 40% lead ore and is capable of furnishing 300 tons of zinc carbonate ores monthly. The smelter at Cerralvo has facilities for the treatment of 35,000 tons of lead ore per annum. Transportation between the mine and smelter and the railroad junction at Herreras is by means of five automobile-trucks.

3. *Providencia Mines.* These mines embrace an acreage of 788 and are capable of producing 4500 tons of lead-silver ores per month, of an average grade of 18% lead and 13 oz. of silver, and also 1500 tons of oxidized zinc ores running about 35% zinc. The ore is transported by an aerial tramway and narrow-gauge railway to the national railway at Saltillo. The zinc ores are sold in the United States and the lead-silver ores are treated at the various smelting-plants controlled by the company. A first-class power-plant is now under construction at these mines. The company has erected dwellings, hospitals, schools, and other modern conveniences for the workmen have been provided.

4. *Guanacevi.* In Guanacevi the company has recently acquired valuable silver properties with a total acreage of 115. As Guanacevi is far removed from the railway and in a district which has for the past two or three years been unsettled, the company has not yet begun operations there. Sufficient work has already been done on the properties to show that they are worth more than the amounts invested. As soon as conditions justify, the company anticipates active operations in this district.

5. *Santa Eulalia.* The Santa Eulalia properties cover 2935 acres, which are operated under lease, with an option to purchase. The leases run from 10 to 15 years and require the payment of a royalty. These properties are still in the development stage. Ores will be transported by aerial tram from Santa Eulalia to the main line of the national railway.

6. *Vera Cruz oil-lands.* Early in 1917, before the enactment of the new oil-land laws in Mexico, which have been the cause of so much dissension, the company acquired 6710 acres of oil-land under leases in the State of Vera Cruz. Some of these properties are adjacent to producing properties and are considered valuable, although no development work has been undertaken owing to high cost of operation and unsettled conditions.

7. *Railway equipment.* The company owns and operates about 30 locomotives and 900 cars, which equipment it was compelled to purchase in order to transport its product over the national lines. Operation is maintained under a contract with the Mexican government. The company has constructed extensive machine-shops at Monterrey, in order to keep its equipment in first-class condition. This equipment is used to haul the products of the company's mines to the smelter and from the mines to the border, and also to haul supplies from the States to the various plants, and has made it possible for the company to continue operation at a time when the service of the national railways could not be depended upon.

8. *Real estate.* The company owns office-buildings at Monterrey, Laredo, and Saltillo; also a recreation park in Monterrey.

9. *Compania de Combustibles Agujita, S. A.* This company was incorporated in 1917 with a captital stock of 65,000 shares of ₱100 each. Of these shares the Minerales Co. owns approximately 55,000, the rest being owned by Mexican citizens. The company owns coal-lands aggregating 2700 acres at Agujita and 1525 acres at Lampacitos. The developed tonnage is estimated at 18,000,000 tons, and the mines are capable of maintaining a production of 45,000 tons per month. A modern washery, recently completed, serves a coking-plant with a capacity of 12,000 tons at Agujita and 500 at Lampacitos. The largest proportion of the output of the Agujita Co., both coal and coke, goes to the Minerales Co. and the national railway lines. The excess is sold to domestic consumers through a fuel-selling company, which the Minerales Co. also controls.

10. *Fuel Sales Co. (Cia. de Combustible Nacional y Transportes, S. A.)* This company was incorporated with 1250 shares of ₱100 each, of which the Minerales owns 750, for the purpose of disposing of the excess production of coal and coke not required by Minerales and its subsidiaries or by the National Railway companies. This company has its own transportation equipment, consisting of three 90-ton locomotives and 60 standard-gauge cars, and maintains a retail-sales agency in Sabinas and Mexico City.

11. *Compania Metallurgica de Torreon.* This company has a capital stock of 50,000 shares of ₱80 par value, of which the Minerales Co. owns approximately 83%. The company owns 503 acres, including mines and a large smelting-plant near Torreon, which is a very central location, having good railway connections. The plant consists of nine lead blast-furnaces and one copper

blast-furnace, with an annual capacity of 400,000 tons. There is a copper converter to take care of the treatment of copper matte, and two Dwight Lloyd roasting machines, and all the necessary auxiliaries, such as power plant, etc. The company has an extensive townsite, with dwellings suitable both for laborers and officials, offices, hospitals, schools, etc. This plant has been operated as a custom smelter for the past 15 years, and is well known throughout the northern mining districts of Mexico. The mining industry has not yet recovered from the effects of the Revolution, and the plant cannot be operated to full capacity at the present time. The normal production of this plant is 20,000 tons of silver lead bullion per annum and 2500 tons of blister copper.

12. *Parrena Mining Co.* The capital stock of this company is P500,000, of which the Minerales Co. owns 50%. The company owns mining properties in the Sierra Mojada district, covering 475 acres, from which are produced lead-silver, copper, and zinc ores. The Parrena Co. also owns a 50% interest in the San Salvador mine in the same district, which has been producing for over 30 years. The Parrena Co.'s own properties are still in the development stage, although the value of the production up to date covers development expenses.

13. *Cia. Minera Paloma y Cabrillas, S. A.* This company has a capital stock of 72,000 shares of P50, which is distributed throughout the United States, Mexico, and foreign countries. The company owns 278 acres of mining properties near Higueras, in the State of Coahuila, and is connected with the National Railway lines at that point by an aerial tramway. It is capable of producing 5000 tons of iron-lead ores containing 15% lead and 3 oz. of silver, and 800 tons of zinc carbonate ores containing 32% zinc. The mine is equipped with adequate power-plant facilities as well as offices, workmen's houses, hospitals, schools, etc.

14. *Compania Minera de Peñoles.* This company has a capital stock of 120,000 shares of P30 each. Its property, which is one of the best and longest known in Mexico, covers 7123 acres, from which 15,000 tons of lead-silver ores are being produced monthly, containing 14% of lead and 13 oz. of silver and 1 oz. of gold. The company also owns and operates a smelter at Mapimi, with five blast-furnaces and necessary roasting-plant for the treatment of 400,000 tons of charge per annum. The company also has an arsenic plant which produces arsenic as a by-product from smelting operations. One power-plant serves both mine and smelter, as well as the town. A narrow-gauge railway of about 25 miles connects both mine and smelter with the National Railway lines at Bermejillo. Both at the mine and smelter, which are about six miles apart, the company has provided adequate housing facilities for between 8000 and 10,000 persons; it also has erected first-class hospitals and schools, and has taken every possible precaution to protect the health and well-being of its employees. The normal production of the plant is 25,000 tons of silver-lead bullion and 5000 tons of white arsenic per annum.

15. *Smelter and Refinery at Monterrey.* In 1918 Minerales perfected a leasing arrangement with the Compania Minera, Fundidora y Afinadora Monterrey, S. A., for the operation of its smelting and refining plant at Monterrey. This plant was recently modernized by its owners, and is now operating under the management of the Minerales staff. It has a capacity for smelting 200,000 tons of lead ores per annum and a refining capacity of 50,000 tons of lead bullion. It also has an electric silver parting plant for the separation of gold and silver, equivalent to a production of 10,000,000 oz. of silver. this plant is engaged primarily in treating ores and bullion controlled by Minerales, but it also handles custom business.

In addition to the above, the Minerales Co. has minority interests in several other companies which it does not operate, and also maintains a trading department for the purpose of facilitating the marketing of its own product as well as for the purchase and sale of the products of independent companies operating in the Republic. Owing to its facilities for transportation and its connection with the American Metal Co. in the States, it is always competitive for such outside purchases, which in the past have been principally of zinc ores.

The corporation, through its subsidiaries and allied companies, owns or controls the following products, the average annual quantities produced being as indicated below:

Electrolytic copper, pounds	100,000,000	to	125,000,000
Zinc (spelter), all grades, tons	75,000	"	100,000
Bonded (Mexican) lead, tons	60,000	"	75,000
Domestic lead, tons	12,000	"	15,000
Sulphuric acid, tons	80,000	"	100,000
White arsenic, tons	4,000	"	6,000
Coal in Pennsylvania, tons	350,000	"	400,000
Coal in Mexico, tons	500,000	"	600,000
Silver ounces	12,000,000	"	15,000,000
Zinc oxide (Polar and Arctic brands), tons	7,000	"	10,000
Zinc dust (American Extra Pure and Zenith brands), tons	3,000	"	4,000
Antimonial lead, tons	1 000	"	1 500
Molybdenum concentrate, tons	500	"	1,000

In addition to its own production of metals, the company buys and sells metals in the open market, and also contracts to take the entire output of various mines, smelters, and refineries in the United States, Canada, Mexico, and South America, as follows:

COPPER

For copper it has contracts with the following (contract calls for entire production):

	Lb. (estimated)
Granby Consolidated M. S. & P. Co., B. C.	50,000,000
Old Dominion Copper M. & S. Co., Arizona	30,000,000
East Butte Copper Mining Co., Montana	22,000,000
Central Chile Copper Co., Panulcillo, Chile	15,000,000
Ducktown Copper, Sulphur & Iron Co., Tennessee	12,000,000
Balbach Smelting & Refining Co., New Jersey	9,000 000
Shannon Copper Co., Arizona	8,000,000
Penn Mining Co., California	4,000,000
Democrata Copper Co., Cananea, Mexico	3,000 000
Ore Trading Co., Santiago, Chile	17,000

Copper Received During 1918

	Lb.
Central Chile Copper Co.	2,858,048
Ducktown Sulphur Copper & Iron Co.	5,116,183
Beer, Sondheimer & Co.	494 227
South American Metal Co.	1,905,248
Old Dominion Copper Co.	12,545,500
Granby Consolidated M. S. & P. Co.	39,115,072
East Butte Copper Co.	23,087,501
Democrata Copper Co.	7,820 889

	Lb.
Shannon Copper Co	6,805,520
Ore Trading Co	13,415,643
Clarksburg Clinkering plant	33,781
Henry R. Merton & Co.	4,028,739
Nichols Copper Co.	9,500,000
Cia de Minerales y Metales	2,399,748
Tintic Mining & Milling Co	214,775
Penn Mining Co	3,121,684
Tezuitlan Copper Co	2,013,195
Balbach Smelting & Refining Co	2,750,085
Ohio & Colorado Smelting Co.	1,145,164
Total	141,398,982

In addition therto the company trades in copper futures and also purchases copper in the open market. The copper is refined by the Balbach Smelting & Refining Co. of New Jersey and the Nichols Copper Co., in both of which American Metal Co. has a substantial interest.

The entire turnover of the company in copper is about 250,000,000 lb. per annum, which is about 15% of the country's total production of copper.

It obtains its zinc ores by contract from the following concerns:

Ores Received July 1916—June 1917

	Lb.
Consolidated Interstate Callahan Mining Co	71,000,000
Butte & Superior Mining Co.	263,000,000
Linden Zinc Co.	3,219,000
Western Chemical Co.	10,000,000
Surprise Mines	1,700,000
Union Basin Mining Co.	57,000,000
Galena Farms Mining Co.	7,000,000
Cia. Minerales y Metales	131,000,000

These ores are treated by the smelters of the company's subsidiaries at Bartlesville, Oklahoma; Langloth, Pennsylvania; and Chanute, Kansas. The average monthly production is about 17,000,000 lb. In addition to this production the company buys and sells spelter on the open market.

The zinc ores purchased by the American Metal Co. and treated by the smelters of its domestic subsidiaries for the two years ended June 30, 1917, amounted to approximately 1,700,000,000 lb. In addition to that, the company purchased spelter during those two years in the open market amounting approximately to 585,000,000 pounds.

Spelter Received During 1918

	Lb.
Consolidated Interstate Callahan Mining Co	22,873,579
Yellow Pine Mining Co.	1,063,546
Butte & Superior Mining Co	58,364,324
Afterthought Copper Co.	636,669
Montana Mines	1,373,088
Yak Mining & Smelting Co	82,828
Judge Mining & Smelting Co	122,245
Joplin Ores	31,029,656
Wisconsin Ores	5,249,719
Cia de Minerales y Metales	11,569,243
Western Chemical Co	2,945,551
Union Basin Mining Co	1,052,744
Surprise Mines	1,242,955
Galena Mining & Milling Co	269,378
Downtown Mining Co.	247,075
Becker Hinraty & Thomas	270,609
	138,993,230

The following are the concerns from whom the Metal company secures the bulk of its supply of lead:

Production for 1917

	Lb.
Cia Minerales y Metales, Mexico	130,000,000
Ohio & Colorado Smelting & Refining Co, Colorado	30,000,000
Balbach Smelting & Refining Co, New Jersey	8,000,000

The company owns over 60% of the stock of the Ohio & Colorado and 97% of the Minerales companies, and 83% of the stock of the Balbach Smelting & Refining Company.

The above figures, except those from Minerales Co., are of domestic lead purchases, but in addition the company buys bonded lead, which is the product of foreign mines and is smelted in bond.

The growth of the company is indicated by the following statistics:

Total sales and net earnings of the corporation after deducting all expenses, profit-sharing, taxes, fixed charges, etc., during the past ten years, have been as follows:

	Capital stock outstanding	Total sales	Net earnings
Year ending July 1, 1909	$3,120,000	$64,274,040.94	$854,719.78
Year ending July 1, 1910	3,500,000	84,402,083.11	685,334.8[illegible]
Year ending July 1, 1911	3,500,000	68,519,481.06	842,780.75
Year ending July 1, 1912	3,500,000	57,060,048.26	1,305,816.12
Year ending July 1, 1913	3,500,000	79,243,602.96	1,001,895.12
Year ending July 1, 1914	3,500,000	68,835,488.65	1,088,770.94
Year ending July 1, 1915	3,500,000	68,468,179.67	2,498,630.83
Year ending July 1, 1916	3,500,000	153,796,848.31	7,638,336.85
Half year ending Dec. 31, 1916	3,500,000	82,615,281.86	4,899,750.50
Year ending Dec. 31, 1917	7,000,000	149,216,409.21	2,802,387.45
Year ending Dec. 31, 1918	7,000,000	106,166,089.07	*832,157.69

*Estimated.

(To be Continued)

Nitrates

An interesting event in the nitrate situation has been the effort of the Government to dispose of its large supplies of nitrate. Stocks amounted to 226,000 tons in the United States, and 120,000 tons in Chile, all acquired at high prices. It has been decided to offer this for sale through the trade with as small a loss as possible, and the first price set was $4.20 per 100 lb. ex vessel at Atlantic and Gulf ports. Early in March this price was cut to $4.07½, this to hold during March and April only. Though this reduction led to increased sales, the price is still high compared with pre-war prices, but the Government is not making any profit. It is thought that manufacturers of explosives also hold considerable stocks of nitrate. Imports of nitrate of soda during February amounted to 44,817 long tons, and during the first half of March were 11,751 tons.—W. C. Phalen in March report of the U. S. Bureau of Mines.

COSTS at the North Star mine, at Grass Valley, California, were as follows during 1918:

Department	Per ton mined	Per ton milled
Mining	$3.870	$5.047
Milling	0.456	0.595
Cyaniding	0.363	0.473
Tailing disposal	0.037	0.048
Bullion charges	0.018	0.024
Miscellaneous	0.251	0.328
New York office	0.116	0.152
Taxes	0.305	0.397
Accident and benefit	0.115	0.150
Development	0.071	0.093
Total	$5.602	$7.307
Less sundry credits	0.010	0.014
Net cost	$5.592	$7.293

Of the ore mined, 8% was discarded as waste, accounting for the two sets of costs. Ore extraction was from the 3400 to the 5000-ft. levels, while development was done down to 6300 ft., on the incline. The ore is crushed by stamps and cyanided, treatment being simple.

Examining a Prospect in Alaska

By F. LE ROI THURMOND

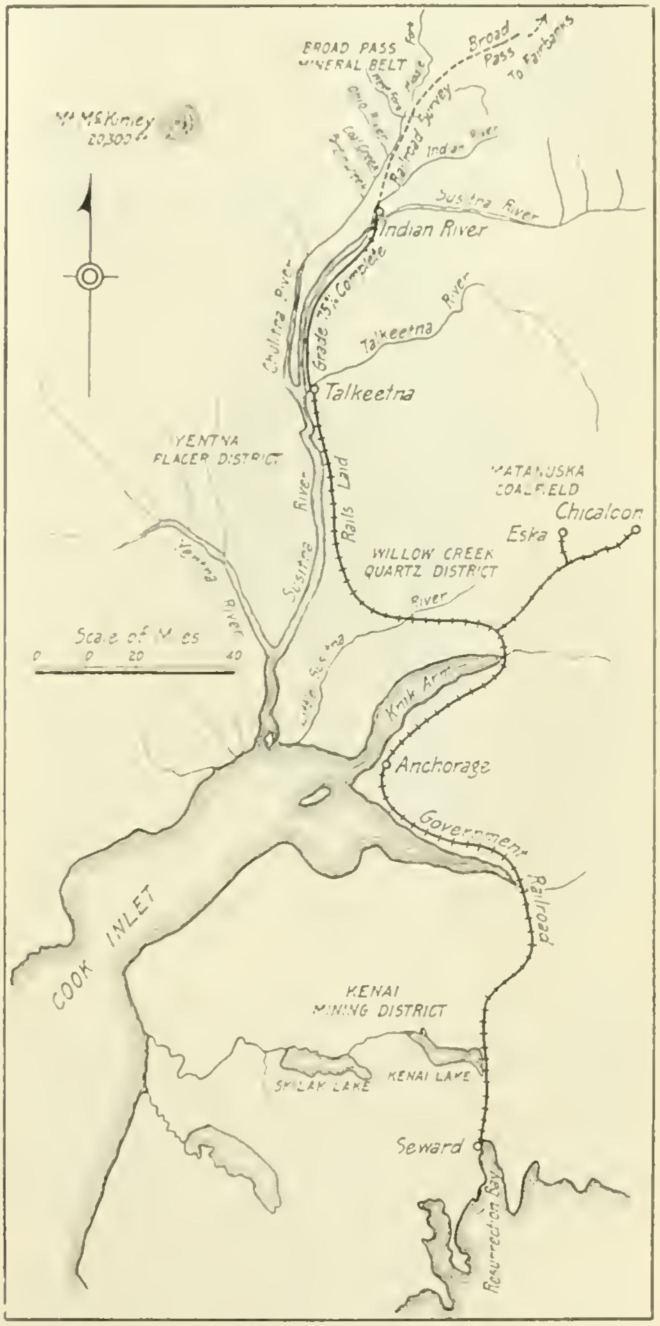
I left Anchorage, in Alaska, on March 14, 1918, in company with 'Doc' McCallie, veteran prospector, dentist, and hard-boiled Westerner, and 'Slim' Neff, dog-musher[1] extraordinary. Our destination was the locality of some claims owned by the doctor near the head of the Ohio river, a small tributary of the Chulitna river and about 30 miles in a north-westerly direction from Mt. McKinley.

The Alaskan Engineering Commission ran an accommodation train to Houston, a station 60 miles from Anchorage, where a coal mine was being operated. All the mushers going north loaded their dogs and outfits into cattle-cars and stowed themselves in Pullmans for this part of the trip. The get-away from Anchorage in the gray winter morning was full of color and sound. Switching engines, bumping cars, hustling baggage-men, cursing, befurred, and mukluked dog-mushers, yelping, snarling, fighting malamutes, near-malamutes, far-malamutes, and non-malamutes, with strains of every canine breed which the fancy of man and exigencies of evolution have produced.[2]

The train finally got away at 8:30 and out onto the low rolling glacial-formed terrain that skirts Knik Arm. The country is thickly wooded with small spruce and several varieties of birch, the latter, extremely graceful in themselves, presented a most pleasing and fantastic appearance with their delicate and intricate boughs covered with a crystalline deposit of frost.

Knik Arm itself appeared when the railroad wound around the base of some bluffs forming the valley-wall. Huge masses of anchor-ice lay stranded at high tide, then miles of hummocky ice-strewn flats marking the upper limits of the tide merging with the overflow from the deltas of the Knik and Matanuska rivers. The road crossed both these rivers close to their deltas and struck north through rolling gravely ground, strewn with innumerable small lakes and swamps, an ideal moose country.

Arriving at Houston at 1:30 p.m., men and dogs detrained and put up at the road-house till the following morning. Here we met a party of mushers who had come over the trail from Fairbanks and who entertained us with vivid accounts of the difficulties of the trail and the hardships that lay before us. The following morning, with a minus 28° temperature, we strung out our dogs and got away flying at 8 o'clock. The trail was well



A PART OF ALASKA, SHOWING LOCALITIES MENTIONED IN THE NARRATIVE beaten and the going good. We did 18 miles by 3 p.m. and were obliged to call it a 'day' if we wished to spend the night at a road-house. Next day a stiff wind blew from the north and with sore muscles we whipped our dogs into it and fought it all day, making 20 miles. We stopped for the night at a tie-camp on Sheep creek. In the morning the wind was blowing with such fury that traveling was impossible, so we laid up all day, glad of the chance to rest. The following morning the wind having subsided, we started for Talkeetna, 23 miles, which we made at 6:30 and stopped at the road-house kept by a Mrs. Small, where the musher's physical requirements were anticipated and well-provided for.

---

[1] We shall abstain from editing the text severely because it is impossible to do so without spoiling its spirit and local color. Alaskans will like the author for using the terms with which they are familiar. A 'mukluk' is a moccasin; a 'malamute' is an Eskimo dog; a 'siwash camp' is a camp without bedding, tent, or other conveniences. 'Siwash' from the French 'sauvage,' is a name given to the Indians of the North-West. A 'sour-dough' is a seasoned frontiersman. These prospectors and woodmen, unable to procure yeast, carry a little can filled with sour dough-batter; with this and by the addition of a little baking-soda they start the leavening of the bread in the form of pancakes, or 'flapjacks'.—Editor.

[2] The word 'musher' is Chinook and comes from the French 'marcher', to walk. It is one of many words brought to the North-West by the French trappers.—Editor.

From Talkeetna the trail lay on the Susitna river, as affording the only feasible route of travel. Our next camp was Dead Horse, 23 miles, where the Alaskan Engineering Commission maintains a large summer camp. Here were mess-house, dormitories, offices, hospitals, barns, and warehouses built of cottonwood lumber sawn on the ground. A watchman and a storekeper were in charge of the camp and provided us accommodations for the night. An incident occurred that served as a warning of the thieving propensities of Alaskan dogs, which will steal and eat anything that has ever been even remotely connected with animal tissue, with a special liking for rawhide snowshoe-thongs. While we were at dinner a stray dog belonging to the camp had torn open the lashings and tarpaulin on our sled and succeeded in dragging out a piece of bacon weighing ten pounds, which constituted a part of our dog feed. He evidently was not very hungry, as he left several square inches of rind, and the gelatine and cloth coating that protected the bacon. His little dinner-party cost us just $4, but he appeared to think it worth the price as he licked his chops well out of the range of boot or other missile.

Another day's march brought us to Indian River at the head of navigation on the Susitna, and the following day we reached the Chulitna river and made camp late in the evening.

The following notes, in the third person, written by one of the members of the party, narrate the incidents of the next few days:

"The party struck bad weather from the start and had to outface old Boreas day after day. On the ninth day out from Anchorage, they left their camp on the Chulitna river in the morning and planned to reach a cache which was known to exist at Shot Gun creek eight miles up the Ohio river—which river is the same as designated "the unnamed river" by Belmore Brown in his account of the successful ascent[3] of Mt. McKinley by himself, Prof. Hershel Parker, and Merle La Voy in 1912.

There was no trail and the soft loose snow had to be packed with snow-shoes before the dogs and sled could negotiate it. The three men would mush on a couple of hundred yards and then back to the dogs. Then the sled would be brought up and left while another piece of trail was beaten down. In the afternoon the wind increased and it started to snow heavily, which added nothing to the gaiety of the occasion. When the mushers would get back to the sled after making a hundred yards ahead, there was no sign of trail, it being completely obliterated by falling and drifting snow. Night came on, the wind and snow increased, the men were exhausted and forced to make a 'siwash' camp for the night. As they did not expect to camp on the road, trusting to stop at caches made the previous summer, they had no cooking utensils or food that could be prepared without, so they spent the night supperless. But thanks to Prometheus or whoever it was that stole the heavenly flame from high Olympus, they had a fire; and if it was a choice between food and fire under such circumstances, the latter would win of necessity.

In the morning after breakfast—the hour, not the act—Slim started up the river to look for the cache, knowing that it must be near. Thurmond started an hour later, the storm was unabated and no sign of Slim's trail could be seen. Thurmond went about three miles up the river, and decided that he had passed the cache, owing to the storm, and turned back. Leaving the river in order to inspect a wooded bench where he suspected the cache might be, he caught a glimpse of a white tent-shaped canvas high up in the spruce tops. It proved to be the cache he was seeking, so he returned to the river and placed a note in a crotched stick and an arrow pointing to the cache for the benefit of Slim whenever he should return from his fruitless search up the river.

Returning to the cache, a tent left standing the previous summer was discovered as a slight unevenness in the expanse of snow. With a shovel from the cache, it was soon dug out. Inside were dry wood and shavings ready for the match, left the previous summer by some real member of the sourdough clan.

Within an hour, rice and biscuits, tea and bacon were ready and Slim came staggering in, having found the sign, too far spent to take off his snow-shoes. He had missed the cache, gone four miles up the river and was going back to the siwash camp for another night. The tea and food put heart and life into both men and they started back to get 'Doc' and the outfit. It was only two miles from the siwash camp to the cache, but two miles of adverse trail in the teeth of a blizzard with spent dogs can yield a sight of grief. All three men, with dogs and outfit, reached the cache at 7 o'clock and supper was gotten, with a feed of rice and bacon for the dogs.

That night a little 7 by 9-ft. tent in the heart of the Alaskan wilderness held more luxury than a king's palace. Ten days the storm continued, snow and wind. It was only four miles to where the party planned to make a permanent camp, but it might as well have been four hundred. Then when the storm had worn itself out they made the remaining distance and established permanent camp, just in time to escape another storm, which playfully hove in from the north and tarried 13 days. During this wind the hard-packed and frozen snow on the river and gravel flats which had been accumulating all winter to a depth of five feet was cut down to the ice and rock by the force of the blast."

---

[3] 'The Conquest of Mt. McKinley', Putnams, 1913.

To continue my narrative in the first person: It was now the 21st of April. I had been out more than a month and had not seen the ground. My information was that as the outcrops had a southern exposure the ground could be examined in April. The unusually late storms and heavy snow had delayed the spring thaw fully two weeks. A trip was made to the ground, three miles farther up the canyon, but as there was no evidence of bare ground we returned to camp to wait until the weather warmed up. The first of May the snow was sufficiently melted to get into a couple of prospect-tunnels, and the next three days were spent in making a rough reconnaissance of the ground, very unsatisfactory, however, on account of lingering snow. As there were signs of the rivers breaking, rendering travel impossible, and my affairs needing my attention in Anchorage, I decided to start on the 5th, leaving the other men, who were going to stay till midsummer to prospect the ground.

ON THE TRAIL

It was now so warm during the day that the snow was mushy and travel impossible, so taking two of the dogs on a light Yukon sled, I started down the river as soon as the night frost had formed a crust sufficient to support dogs and sled, at about 1:30 a.m. At this time of the year the sun was so far north that it gave light enough to travel all night. It was a crisp morning when I left and as the sled went slipping down the river, a cock ptarmigan resplendent in his mating finery got up from under the leading dog's nose and flew sputtering and cackling a hundred yards down the river, where he strutted and fretted for the benefit of any lady ptarmigan who might be in the vicinity.

About 2:30 a splash of crimson in the north-east heralded the rising sun and for the next two hours a truly amazing kaleidescope of color fascinated and awed me. In all the catalogue of Nature's wonders there is nothing more sublime than a sunrise in the mountains of the North.

I had covered 20 miles by the time that the trail got soft, at 9 a.m., so I unhitched the dogs and tied them under a tree, rolled myself in a blanket and went to sleep. I awoke about six o'clock, gave the dogs each about a pound of bacon and ate a biscuit myself. Then I hitched up the dogs and hit the trail with snow-shoes, putting the dogs on a long lead and taking the gee-pole, as the crust would not support me on the sled at this hour in the evening. I had to cross a wooded summit of about six miles, between the Chulitna and the Indian river, and the going through brush and timber was extremely rough. To anyone interested in synchronized movements, I would recommend a study made on snow-shoes astraddle of a tow-line, with a gee-pole in hand, on a trail that seems bent on describing a straight line—by antithesis.

THE AUTHOR

By the time I reached Indian river and the snow was well crusted, I had gotten up a sweat that soaked my clothing. To have ridden on the sled in such condition would most certainly have been folly, so I built a snappy fire of the dry twigs and limbs that are found around the base of the spruce, and so dried and warmed myself, before going further.

An hour's run down the river brought me to a canyon where the river was open from wall to wall. Sounding it with a pole, I found I could wade it, so pulled off my socks to keep them dry, rolled up trousers, and with my 'packs'[4] on my feet to protect them from rocks and ice, I

[4] A 'pack' or 'shoe-pack' is a moccasin made of waxed hide. 'Cache' is a French word; it means a place for concealing or storing anything, especially provisions.—Editor.

waded across, carrying dogs and outfit, necessitating three trips. My feet were paralyzed from the icy water; but after getting my socks on, and stamping around to warm my feet, I started again, running behind the sled. A hundred yards farther, and I ran into another hole and had to repeat the performance.

Getting out of this, I continued down-river, running hard behind the sled to restore circulation in my feet. I was just leaving the river-trail to take a short cut through the woods when my dogs stopped and began to bark furiously. I got out my revolver, as I suspected that it might be a brown bear which had early crawled out of its winter quarters and might consider myself or dogs as suitable spring forage. Peering down the river, I saw a moving body and heard the voices of men and barking of dogs. They were going into the country I had just left and as 'Doc.' and Slim were short of sugar and I desired to send them some, I invited one of the men to accompany me back to Indian River station where I would get the sugar and give my dogs and sled to him if he would carry it to 'Doc.' This he agreed to do. Arriving at Indian River about 2:30 I procured the sugar and despatched him, while I got a cup of coffee and a bite to eat, and was off on foot down the Susitna river. The snow was hard-crusted and the going so splendid that I wished to put as much of the trail behind me as possible while the crust lasted. I carried my snow-shoes for an emergency, but snow-shoes in mushy snow are only a little better than none. I arrived at Dead Horse, 20 miles, at 2 p.m., having traveled 55 miles since the previous morning. I was worn and hungry, so, after a lunch, I lay down to sleep leaving instructions to call me at midnight, when, after a little breakfast, I again hit the trail, and arrived at Talkeetna, 23 miles, at 10:30. Here the river was breaking up and the snow almost gone. Resting another night I found the trail bare of snow and the following day I walked into Houston, from where we had started with our dogs, six weeks earlier, and boarded a train for the final lap to Anchorage.

My trip, while absorbing six weeks' time, was productive of such meager information that I was again commissioned to visit the property late in the summer. Accordingly, I left Anchorage on August 22 and traveled by train to Montana Creek, 35 miles farther than on the previous journey. Here, after waiting two days, I got passage up the river on a boat belonging to the Alaskan Engineering Commission, a fleet of these boats being engaged in distributing material and supplies for the railroad construction from Montana Creek to Indian River. The first day an incident occurred that disturbed the monotony of the lazy summer afternoon. I am moved to remark in passing that there are more ways of killing a bear than letting daylight through his innards with a vest-pocket siege-gun, but the following way, which came under my observation, is not one of them.

I was lying asleep in a berth in the pilot-house of the B. and B. No. 2, while the boat was rapidly steaming up-river at the rate of a mile an hour when I was startled by some one shouting "Bear!" I came to with camera in hand and got out on the bow before any considerable quantity of time had flown. Looking up-stream and toward the right bank I saw a big bear wade out into the stream and start to swim across. The current carried him down-stream and his attention being attracted by the movement of the boat, he turned and started to swim directly toward it. Standing on the bow, I pulled out the camera to a 100-ft. focus and set the shutter and diaphragm, after consulting my exposure metre, and waited for eventualities. They were not long in arriving. The boat was going up-stream, the bear down, each seemed bent on making the acquaintance of the other, and it looked like something ought to happen. The bear came up to within five feet of where I stood on the low flat deck, with one eye appraising the various points of vantage among the cargo, in case the bear decided to take passage on the boat, and the other steely gazing right into those of Mr.—or Mrs.—Bruin, I snapped the camera. About that time the action commenced. A deck-hand made a lunge at the bear with a pike-pole and caught him just abaft the shoulder. The pike would have gone through, had not the right-angle prong prevented. As it was, it gave bruin quite a shock and rolled him over in the water, when another deck-hand tried to fish him in with the hook of his pike. Just what he intended doing with the bear when he should get him on deck, I failed to comprehend. The bear, his feelings injured by the reception he had met, allowed the current to carry him past the boat, when the captain thought to take a hand in the chase, and put the wheel hard over, intending to turn and follow the bear down river. The boat had turned through about 140° and was going down-stream at a pace when the bottom of the river came up and hit the keel a wallop. The boat took the count on a sand-bar, while bruin swam across the river and crawled out, shook himself, and with a bare glance at the stranded boat, bade farewell to the scene. I turned to close my camera and noticed the focusing scale set at 100 ft.—and the bear was only five feet away when I snapped the shutter! Being handicapped in the matter of expression, speaking only two languages, American and profane, I forbore, and charged up the loss of a rare picture to buck fever, while I went to help the crew get the boat off the sand-bar.

Three days on the river and I arrived at Indian River station, where I was met by Jack Frisby, a guide with a pack-horse, and the following morning we proceeded, following the same trail I had traveled by dog-team in the winter, for about 20 miles, when instead of crossing the Chulitna river, we went up-stream to the forks, crossed the east fork and camped for the night on the west fork in an old cabin near the Golden Zone property of the Wells brothers, which was the scene of considerable excitement and activity in 1914 and 1915.

During the afternoon we passed a U. S. G. S. party in charge of D. C. Witherspoon, dean of topographers, and I made arrangements with J. E. Luttrell, one of the party, to meet me on the Ohio river in five days and conduct me to a property that he owned on Partin creek and which he was desirous that I examine. We also passed a big brown bear in a blueberry patch busily engaged in building up calories against the long hard winter.

In the cabin where we camped I found a note from a prospector whom I had met on the trail the previous winter. He had frozen his feet the night we siwashed on the Ohio river and had lived in the cabin several months while waiting for them to heal. His body was found several weeks later on a sand-bar of the west fork by Witherspoon's party. It appeared that he had lost his life while attempting to ford the river and had been dead several months when found.

The following morning we climbed out of the valley of the west fork and struck across the hills toward the Ohio river. We were in an open country above timber-line, with easy contours and pleasant traveling. The ground was cut up with caribou trails made in previous years, when great herds made their spring and fall migrations between their summer range on the flanks of Mt. McKinley and the northern slope of the Alaskan range, where the snow is less heavy in winter. We saw no caribou, as they are becoming very scarce in this region, but many bear, both black and brown: the rightly-respected *Ursus Gyas* of south-western Alaska, the largest member of the bear family, and judging from abundant evidence, the most ill-natured. Blueberries grew in great profusion and furnished a most appetizing lunch whenever it pleased our fancy. They were a welcome change from bacon and bannocks. Bears are very fond of blueberries and hardly a day but we passed one or more, busily devouring the sweet little fruit. We carried no guns, not wishing to be detained by hunting or killing of game.

We reached our destination in 11 days from Anchorage. I spent five days in examining the property and making a reconnaissance survey. We then packed up and started down the river, expecting to meet Luttrell at Pauley's cache on Shot Gun creek, as we had arranged. Arriving there at noon, we found no sign of him. After a meal I sent my guide and packer out with the samples I had taken while I started across the mountains alone to examine Luttrell's prospect, knowing that there was a prospector in there whom I could depend on for food if the meager supply I had gave out. I traveled all afternoon up a mountain slope, carrying about 40 pounds: camera, tripod, used with Brunton compass and camera, tape, note-book, biscuits, and chocolate. At night, I found I had followed the wrong fork of Shot Gun creek and was obliged to camp a long way above timber-line, near a glacier.

The following notes are taken from my diary from September 6 to 12.

"Sept. 6. I am writing this somewhere near the top of the world, left camp on Ohio river this a.m. 7:30. A beautiful day. The sun shone magnificently. We traveled to Pauley's cache, on Shot Gun creek, where we unpacked and lunched. I then sent Frisby out by the west fork. I took nine biscuits, a pound of bacon, 1½ lb. sweet chocolate, my 30-40 rifle, 12 shells, camera, Brunton compass, and tripod, and started over the mountain, following the north fork of Shot Gun creek. The first thousand feet of elevation was through heavy alders; then I came out on the open mountain. I was tired when starting and it became a task to force my legs and lungs to do the work of carrying me. I kept up all afternoon and estimate that I have traveled 10 miles and climbed 3000 ft. Once on looking miles across the valley of the Ohio river I saw Frisby's horse outlined against the sky and then disappear down the opposite slope. A feeling of uneasiness attacked me. For all that I knew to the contrary, I was the only human being in the vast territory west of the Chulitna river, and with rations for only three or four days at the most.

All about me are bare and mighty mountains. I am on a summit and near a great ice-field in which the stream I have been following heads. The cold wind from the glacier is sending a chill into my bones, through sweat-soaked clothing. There is absolutely no fuel here, not a twig. I will have to go down into the valley where there are probably willows. It is 9:30. The sun has just set behind a great sawtooth range and the mountains stand out against a lambent sky, like barriers against the invasion of the mysterious region beyond. To the south-east, two hundred miles away, I can see the snow-clad summits of the south-eastern arm of the great crescent of the Alaska range, lavishly painted by the setting sun. A peculiar phenomenon is seen in the North. Great rays of pink, violet, and amethyst radiate from a point on the horizon near the magnetic pole. The phenomenon resembles the Northern Lights but, in the rarer tints of the evening sky, surpasses the Aurora in delicacy of coloring.

I am getting cold. I hear a noise on the slope below—a bear probably. I must descend into the valley and see if I can find some fuel. I shall freeze here.

Sept. 7—8 a.m. Went part way down the mountain last night. Found some small willows in a gulch, enough to keep a handful of fire all night. Found this morning I was in a glacial cirque with no way out except the way I came in. I am on the wrong fork of the creek, should have taken the first creek to the left and crossed this one. It is starting to rain. I will go back to Pauley's cache, stay there tonight and start again in the morning.

Sept. 8—7 a.m. Made Pauley's cache at two o'clock, slept three hours, feel much refreshed. No grub in cache except rice, no salt or sugar but some coffee. Boiled a piece of bacon which I had left in order to get some salty water to cook rice. It is raining hard today. Streams rising. I cannot get across the Ohio river to follow Frisby if I would, so I must make another try for Partin creek.

8 p.m. Tried to get over to Partin creek today; rained hard and snowed. Had to wade the creek through canyons, and fight alders. Got above timber five miles up-creek, drenched to the hide, cold wind cut to bone, sapped my strength. Decided it suicidal to continue—no fuel—turned and stumbled down-hill through drenched grass and dripping alders. Waded in creek, grasping overhanging alders to keep my feet, too numb with cold

and weakness to fight a way through the tangled alders. Nearly perished. Did not think I would get back to Pauley's cache. The cold had sunk into my bones and was paralyzing me. Got back to Pauley's cache about three o'clock, got a fire started, and wet clothes off while a pot of coffee was making. The coffee and fire set my blood to circulating and I sat naked by the fire, letting the warmth soak in.

Sept. 9. Yesterday's exposure affected my heart and lungs. Ate some rice without salt for breakfast and it sickened me. Have still got coffee. Rained all night, snow on summits. I cannot travel today and have no food. There is an old cache across Shot Gun creek which I am going to investigate if I can fall a tree so as bridge the creek.

Later. Got sugar, salt, beans, and flour in cache; have enough to eat for ten days; found an old mouth-organ in cache, gave it a sterilizing bath and tried to play on it, found it had but one tune, "Home Sweet Home", so I threw the damn thing away. Found a few disconnected leaves of a serial story in a fiction classic, 'Adventure' and am having a literary debauch. Have developed pleurisy from exposure yesterday, cannot travel until it gets better and storm quits. Wonder how the War goes. Fifteen days since I left Indian creek. The rivers are raging and could not cross them without a horse. May have to stay here until freeze-up and get out on ice.

Sept. 10. Rained all night, furiously. Ate no breakfast, but drank a cup of coffee. Have only coffee enough for two more days. Then I will be in bad. Prospected right bank of Shot Gun, got a few fine colors. Took rifle and went a distance up-creek, looking for a bear. Did not find him. Snow came down to about 3000 ft. last night; clearing up today. If sun shines tomorrow, will make another try for Partin creek.

Sept. 11. My stock went down last night. It was raining when I went to sleep. On waking this morning, not hearing the pelting on tent, thought it had stopped. Looking out, found it had—and then snowed a foot. Things look black. What now? I am too weak to travel. The sole has come off one shoe from continual wetting and climbing over rocks. It is 80 miles and five rivers to cross to get to Indian.

Sept. 12. Made Partin creek and found prospector's camp at 4:30. Heart-breaking trip over mountain through snow mid-leg deep. Saw and photographed tracks of big brown bear. Saw ptarmigan changing to winter coat. Rock formation sedimentary. Found vein in gulch near head of creek, 12 ft. wide. Took a small hasty sample. From summit saw two white objects in valley of Partin creek, thought they were tents, not sure, got down, found it so, crazy prospector named Partin in one of them."

Returning to my narrative. I rested a day with Partin and then the following morning had him guide me to the prospect that I was seeking, where I made a brief examination and returned to his camp in the evening. As it was nearly 100 miles to Indian River and four glacial streams to cross, to return by the way I came, I decided to attempt a crossing of the Chulitna river and thus save about 60 miles. As Partin wished to go out with me, we left his camp on the morning of the 15th and made a stop on the banks of the Chulitna that night. It rained steadily, so that we were obliged to stand up all night. The following day we built a raft. While getting out timbers, I was obliged to climb a birch to cut off a limb that had caught and held a dry spruce which we desired for our raft. When half-way through the limb, it suddenly snapped and pinned me in the crotch of the tree. Partin climbed the tree and with a hand-spike released my leg, which felt as if it had been broken, but after getting the circulation restored, found it uninjured.

Our raft was completed just before dark and as the river was rising and becoming more obstreperous, owing to the continual rain, I decided to make the crossing at once. We had built the raft just below a canyon where the current was confined to one channel, and which, immediately below, split into many channels where it traversed a wide gravel-bar. It was my plan to launch the raft where the current set toward the opposite bank and with the aid of a steering oar, so angle it that the current would force it across, before getting into the split channels.

A mile and a half below was a box canyon through which no raft could live and to enter which meant certain destruction. We had a pair of oars rigged to help in getting across. Partin manned the oars and I handled the tail-sweep. I pushed it out into the stream and when she began to throb, jumped on, and yelled to Partin to pull. Before I got control with the sweep, the current caught and whirled the raft around several times and threw it against a snag in mid-stream, which was just on the dividing line between safety and disaster. She swung around and went down the wrong split of the channel. We were in mid-stream and going fast. The opposite bank of the channel was the inner side of a curve and by angling the raft against the current I calculated to get close enough to jump. Partin was crazy with fear and was predicting disaster and wailing when I shut him up in a manner more effective than polite. "Pull! You blankety blank fool, or you'll have supper in hell and a gullet full of Chulitna mud!" He shut up and applied himself to the sweeps. We were nearing the point of the bend and I saw we would miss it, so I yelled to Partin to jump, and with knapsack in hand I followed. It was shallow enough to gain a footing and we climbed out while the raft went whirling down toward the canyon.

The problem that confronted us now was to get across the remaining channels. By cautiously fording at the widest places and using a stick between us, one upstream, the other down, we made the opposite bank after wading eleven channels.

It was now dark, and we built a big fire under a friendly spruce and proceeded to siwash it another night. We boiled a little rice and made some coffee, and spent the night drying our clothing. In the morning, after more coffee and rice, we started for Indian River. It

FIELDS OF WILD COTTON ON THE EAGLE RIVER NEAR JUNEAU

AT THE HEAD OF NAVIGATION ON THE SUSITNA RIVER, ALASKA started to snow as we left camp and continued to snow steadily all day.

We followed a blaze going in our general direction until noon when the blaze was lost in a swamp; we traveled by compass until we struck a survey where the brush was cut and traveling was easier. The snow was soft and wet and lay on one's shoulders until it melted and ran through and trickled down one's spine and oozed out of one's boots. Our way lay through a spruce swamp that had been surveyed and re-surveyed as a feasible route for the railroad, three parties having left blazes and slashings, intersecting the swamp. Travel by compass across the swamp was extremely difficult and irksome owing to a tangle of brush and the soft snow and tundra. So we followed several blazes and cuttings until we lost them in a bog, or in a labyrinth of criss-cross trails that marked the site of a survey-camp. We were seeking to intersect the main trail, the position of which I was fairly well aware.

There was a big tent on the trail used by horse-wranglers packing to the survey party which was now working on the east fork. Partin said he knew where the tent was and as he had been over the trail many times I trusted to his instinct to guide him aright. It was growing dark, we had been going all day, cold and wet and hungry, to say nothing of weariness after two nights of sleeping on our feet. Partin said we were near the tent and would make it in less than a mile. I was nearly ready to drop. We finally came to the track of two men in the fresh snow, not over an hour old. Partin yelled that we were saved. I examined the tracks, and shuffled off my pack—decided it was time to camp when one begins to walk around in circles. Partin, the damn fool, would not believe they were our own tracks.

We rustled a little dry wood from under the wet snow and with the aid of the dry twigs that I found around the butts of swamp spruce got a fire going. We cut down a green spruce about a foot in diameter to have fuel enough to last till morning. It rained and snowed all night. We could not lie down or even sit down. The ground was swimming; our clothing was saturated. We boiled and ate the last of our rice, about four ounces for each.

That was the most awful night I ever lived through, with every fibre of my body shrieking for rest—cold, wet, and hungry. Standing before the fire unable to relax, I was still able to jest. Partin, the demented, was morose and dispirited. Toward morning I lost consciousness long enough to fall forward into the dying fire. I broke the fall and prevented a burn by reaching instinctively and grasping the unburned end of the green log.

As soon as it was light we started again, I taking the lead and going entirely by compass, turning only for several small lakes. The going was desperately hard, over snow-covered tundra and through tangled snow-laden brush. Toward eleven o'clock, I felt myself growing weak and my legs frequently gave way under me. We were not making much progress, it still snowed and I knew that we were in a serious position. I was sure that another night out would do for us and leave our bones for the wolverines.

I took off my pack and threw away some samples which I had packed for three days, also my tripod for camera and compass. They would be no good to me or the wolverines, and I stood a better chance of getting out if I lightened my load. In half an hour I had found the trail and after following it for two miles came to the wranglers' tent.

It was in a mud-hole made by horses' hoofs; the snow had broken it down, there was several inches of mud and water in it and the rain ran through the roof in streams. There was a battered camp-stove on stilts, and the pipe had blown down. There was no wood cut, but there was one dry corner in the tent and some food in a box.

It was real salvation and if I ever get to Paradise, I know that I will not have more of joy than percolated through my blunted consciousness when it hove in sight. While Partin got wood, I started the fire and made a dive into the grub-box. I found a can of Van Camp's pork and beans, and with a benediction on old Van and an axe I cut it open and emptied it into a skillet with about a pound of bacon-drippings and then listened to the heavenly music while they sputtered in the pan. Then I found a tin of corned beef and sent it to join the beans and then made a gallon of coffee, specific gravity about 2.5, and then finding a box of macaroni, I boiled and drained a pot of it and slithered it in butter and it followed the beans and corned beef and coffee. Then, the edge of our appetite being somewhat blunted, we proceeded to dry our clothing. When the pack train pulled up, and started to unload, it was bringing out Secrists' locating party, which had just finished its season's work in Broad Pass. There were 15 horses and 10 men, including Lon Wells and Jack Coffee, old-time prospectors and guides, and J. L. McPherson, secretary of the Alaska Bureau of the Seattle Chamber of Commerce, who was on his way to the coast from Nenana, after having made his annual tour of Alaska. They carried a cook and a generous supply of food and after camp was established, a lean-to covered with a 'tarp' [tarpaulin] and a reflector of green logs for the fire in front, the tent repaired and carpeted with boughs, a supper was prepared in which we were invited to join.

McPherson shared his blankets with me under the lean-to, but the physical reaction was so severe that I could not sleep and suffered severely all night with muscular contortions and mental phantoms. The next morning after breakfast, we all continued the journey and arrived at Indian River in the middle of the afternoon. From there the following day we went down-stream on the 'Betty M.' to Montana Creek and thence to Anchorage over the railroad.

Water-jackets in use since June 1913 at the blast-furnace plant of the Calumet & Arizona were replaced in 1918. The deterioration was confined almost entirely to the inside of the water space, the outside face showing little wear.

The Iron and Coal of France

Frank H. Probert, consulting engineer of the U. S. Bureau of Mines, and dean of the College of Mining, University of California, member of a special American Commission to investigate the damage done by the Germans during the War to the coal and iron and steel works of France and Belgium, after a personal investigation, has just returned to Washington with a first-hand story of the almost unbelievable atrocities of the Hun in the destruction and wreckage of the industrial life of France and Belgium. In a preliminary report, he says:

"Early in the War the German hordes swept southward through the iron basins of French Alsace and Lorraine, and for nearly four years this renowned mining area was held and exploited by the invaders. Many of the employees were made captives and compelled to work in the mines under German direction. The international boundary between France and Germany was drawn in 1871, to give the victor of the Franco-Prussian war control of the iron-fields, but since that time scientific development, guided by a better understanding of the local geology, exposed for France a greater ore-reserve at lower horizons than that of Lorraine Annexeé. With the return of Alsace and Lorraine to the mother land, France will become the dominant factor in the future steel industry of Europe. During the German occupation, the iron mines were not intensively exploited because of the necessity of recruiting into the Teuton army every able-bodied man and on account of the large accumulation of minerals in preparation for the War. The actual physical damage to the iron mines is relatively small when compared with the destruction of the coal-fields of northern France, which was as reprehensible as it was complete. Only in a few cases, where pillars have been robbed, is there any collapse of underground workings in the iron mines, but the equipment, both surface and underground, has been misused, and where ore has been mined, the lack of development will defer realization of capital until the exploratory work is sufficiently advanced to admit of daily output approximating pre-war conditions. The mines are not seriously crippled, but what of the steel plants in which the iron ores are smelted? No such atrocity was ever perpetrated against the industrial life of any country. Magnificent plants, comparing favorably with anything we have in the United States, are now but a tangled twisted mass of structural steel and broken stone. The wilful demolition was scientifically planned and systematically carried out. This after the removal of all such mechanical and electrical power units as could be used in Germany. The maliciousness and efficiency with which this crime against French industry was conducted is almost unbelievable.

In the coal districts of the Pas de Calais and the Nord, a sector fought over from the beginning to the end of the War, changing hands frequently, bombarded all the time, all surface structures whether of town, village, or mining enterprise have been razed. This may be legitimate warfare, but now that the guns are silenced and the frenzy of combat is past, it is horrible to look upon. Arras, Douai, Bethune, Bapaume, Lens, Loos, Courriere, centres of coal-mining activity but a few years ago and the mainspring of French industrial life, are gone, but the indomitable spirit of France survives and already plans are laid for the future. Bruay, at the western edge of the known coal-field, was not in the fighting zone and its output has been steadily maintained, but going eastward the frightfulness is more and more appalling, for the hate of the Hun left its mark on the mines during his forced retreat. The coal measures are overlain by water-bearing strata, necessitating special methods of shaft-sinking and support to keep the mines dry. The steel lining of the shafts was dynamited, letting in the quicksand and flooding the underground workings for many miles. In the entire Pas de Calais region it is estimated that 120 million cubic metres of water must be pumped before mining operations are resumed. Having flooded the mines, the head-frames and surface equipment were systematically dynamited, the twisted debris in many cases filling up the demolished shafts. It will probably be five years before this coal district can be rehabilitated and twelve to fifteen years before it gets back to normal pre-war output. The first great need is for buildings in which to house the workman.

The Saar coal-fields were visited by the Bureau of Mines officials. Here, in striking contrast to the mining districts of France and Belgium, the coal industry is at its height. German workmen and German engineers are still employed, but under the direction and supervision of French officers. A spirit of unrest is apparent everywhere, the suspense of the peace negotiations, uncertainty as to indemnity to be exacted, and lack of food, is telling on the already broken morale of the German workmen. Unfortunately the Saar coal does not give a desirable metallurgical coke to the French and the blast-furnaces now running are working inefficiently.

The French attitude toward her allies is an interesting psychological study. France has been hurt, really hurt by the long conflict. She has suffered perhaps more than any other nation, the battles have been fought mostly on her soil, her manhood has been drained of its best and most productive blood, her industries, her economic mainsprings have been ruthlessly destroyed. These two classes of French thought are desirous that France re-build herself, financed by German indemnity. They seek neither money nor advice from others; the irrespressible spirit will be all sustaining. Directors of industry, mine-owners, and employers of labor, possessed of the same love of country, look on the problem from another viewpoint. They claim that money borrowed from other countries at reasonable interest rates, new equipment for mines and plants purchased from America for early delivery, will admit of an earlier return to pre-war scale of operation and the higher immediate cost will be more than offset by the earlier realization of profits from natural resources and raw materials.

REVIEW OF MINING

ALMA, COLORADO

SILVER MINING IN PARK COUNTY

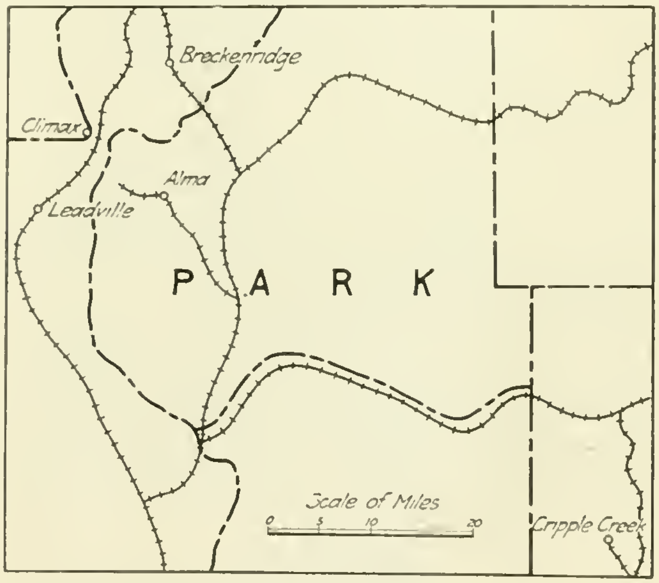
Park county is experiencing more activity in mining than for many years, as the old silver properties, which have lain dormant for so many years, are now being re-opened, and are revealing large bodies of good milling and some rich ore already developed in the old workings.

The Moose mine, on Mt. Bross, has been purchased by the Louisiana-Colorado Mining Co. from the estate of Ludlow Patton of New York, and is to be re-opened. This company now owns 40 claims, equal to about 450 acres. It entered this field during 1917 and purchased the Dolly Varden property, which adjoins the Moose on the south, and immediately started erection of a 150-ton flotation plant and an 8000-ft. aerial tram from mine to mill. These were completed late last fall. A trial-run was made and two cars of concentrate was shipped to the smelter at Denver, which gave returns of 0.02 oz. gold, 177 oz. silver, and 4½% lead. The mill is now being equipped with a concentrate dryer and other machinery, and will be in full operation within a few weeks. E. A. Ritter, who is in charge, has succeeded in finding the fault that displaced the porphyry dike, along which the ore occurred in the old workings of the Dolly Varden, and is now driving a drift along the fault-plane to pick up the dike and the ore-shoot on their extension to the west. A discovery recently made in the workings known as the Drum Major tunnel bids fair to prove important. A flat contact deposit of from 8 to 10 ft. thick has been opened 200 ft., without coming to the limits of the ore. The whole orebody will average about 40 oz. of silver per ton just as the ore is broken, the first lot assorted for shipment returning 0.8 oz. gold, 388 oz. silver, 31% lead, and 3.65% copper.

The Louisiana-Colorado company was financed by southern capitalists, the officers consisting of A. J. Trone, president; E. A. Ritter, vice-president; and A. J. Brand, secretary-treasurer. These with Eugene Constantin, J. W. Lepine, W. H. Price, and Dr. Thomas Stark compose the board of directors.

The Reserve Mining Co., under the directorship of the State Treasurer, Harry E. Mulnix, Judge M. S. Bailey, and Senator James Moynahan, has acquired the Mineral Park property, which is directly under the Dolly Varden and covers the same mineral-bearing contact as the latter; and the Hoil group of 40 acres at the foot of Mt. Lincoln. The Hoil has produced the highest grade silver ore ever mined in the Alma district, and while the workings are in much the same condition as those of the Dolly Varden when that property was taken over, it bids fair to rival the latter in the quantity of developed ore. The work of re-opening the tunnels will be undertaken as soon as spring opens.

The Fanny Barret Mining & Leasing Co., under the directorship of A. D. Aitken, W. H. Spurgeon, and N. B. Cool, of Colorado Springs, has secured the Fanny Barret property on Mt. Loveland, and is erecting an aerial tram to facilitate movement of ore. This property has a substantial production of high-grade silver ore, and the tunnel now being driven will re-open the ore known to exist in the mineralized section adjacent to the old workings.



PART OF COLORADO, SHOWING PARK COUNTY

The Orphan Boy mine is being operated under lease and option by E. P. Young and associates. A few men are employed in cleaning-up the workings and getting ready for early operation.

G. W. Logan, manager for the Silver Tip Mining Co., states that work will be resumed on the Hock Hocking mine shortly. This property is equipped with a modern mill, and at the present price of silver should yield good profits from the ore now developed.

The London mine never looked better than at present. A steady production of ore assaying over 5 oz. is being sent out from the different leases in the upper workings. The London Mining & Milling Co., the owner, has erected a new compressor and will resume driving the lower tunnel, which will cut the vein 600 ft. deeper. The manager, C. P. Aicher, expects to have about 200 men employed before next fall.

The J. G. Blaine mine, under the management of J. E. Dollison, is being operated by Pittsburg people and shipments of grey copper ore, high in silver, are being made.

Development has been carried on with a small force at the Colorado Springs group for the past year, and it is now rumored that the transmission-line of the Colorado Power Co. is to be extended to this property and extensive development undertaken.

The Commonwealth Mining Co., with a large number of claims on North Star mountain, including the Magnolia and Lee Goss, will resume operations this spring, after an enforced idleness of a year, due to labor shortage. The aerial tram should be in running order by July 1. The ores will be treated in the Eddy mill, which has been remodeled for cyanidation.

The orebody cut in the workings of the Russia mine, while not as yet developed sufficiently to determine its size, promises to be extensive. The ore occurs in blanket form, is about 6 ft. thick, and averages 20 oz. silver per ton as mined. Negotiations are now pending that may result in the installation of machinery and extensive development.

The No End mine is being worked with a few men, by Warren F. Page and associates of Leadville. This property is situated in a highly-mineralized area, and adjoins the Great West mine, which made an output of rich gold and silver ore some years ago.

The Sun-Moon Leasing Co. has had 15 men employed on development for several months past. Several carloads of silver-lead ore have been shipped, and a steady output will be maintained during the summer. The property, known as the Hill Top, is in the Horse Shoe district, and has produced a large tonnage of silver, lead, and zinc carbonate ore.

BUTTE, MONTANA

ENGINEERS HOLD ANNUAL MEETING.—BUTTE & SUPERIOR INCREASES OUTPUT.—DAVIS-DALY TO IMPROVE EQUIPMENT.

The Montana Society of Engineers held its annual meeting at Great Falls on April 10 and 11. On the second day they inspected the new hydro-electric power-plant at Volta on the Missouri river, 13 miles from Great Falls. Current is generated at 100,000 volts by turbine-driven generators suspended on Armstrong bearings. The turbines are 155 ft. below the crest of the dam, which is 90 ft. high, and of solid concrete construction. On that afternoon the party also visited the new copper wire and rod plant at Great Falls. Here, the copper from the electrolytic refinery is melted, cast into wire billets, and rolled into the size of wire desired. At the present time the Chicago, Milwaukee & St. Paul Railroad is taking practically the entire output for the electrification of its road between Othello and Seattle. Next the electrolytic-zinc plant of the Anaconda was visited, where the process of leaching and precipitation was explained. On the 12th the party visited the filtration plant of the Great Falls water-works; and in the afternoon the annual meeting and banquet was held, at which the following officers were elected for the ensuing year: Samuel Barker, of Butte, president; C. A. Lemon, of Anaconda, first vice-president; George T. McGee, of Helena, second vice-president; C. H. Moore, of Butte, secretary; and H. H. Cochrane, of Butte, treasurer. After the business meeting the retiring president gave an address, and D. C. Bard, of Butte, gave a scheme for consolidation of the Montana Society of Engineers with the five national engineering societies as outlined by Mr. Rice, a member of the American Society of Mechanical Engineers.

The Butte & Superior Mining Co. has recently increased its output. Since November it has been operating at 50% capacity, but at present work is up to about 80%.

The Davis-Daly Copper Co.'s directors have been inspecting the property, and report that plans are under way for improvement of the surface equipment at the Colorado shaft, which will materially decrease costs. The party consisted of H. M. Burton, president; Charles G. Schrimer, secretary-treasurer; William Bloom, vice-president; Frank A. Schrimer, and Fred M. Kimball.

VICTORIA, BRITISH COLUMBIA

PRODUCTION OF IRON.—FOREIGN METALS.—OIL INVESTIGATION.—MINING ON INDIAN RESERVATIONS.—SMELTER SMOKE.—BELMONT SURF INLET DECLARES FIRST DIVIDEND. — NEW 8-HOUR LAW EFFECTIVE. — FRENCH PROCESS.

There was one fatality in the metal mines of British Columbia during the first quarter of the current year, compared with three in the same period of 1918. The death referred to was caused by a skip in the shaft of the Belmont Surf Inlet mine, Princess Royal island.

Experiments are soon to be started to determine the practicability of producing iron from British Columbian ores within the Province. The authority for this was given the Minister of Mines by an act passed at the recent session of the Provincial Legislature. Instructions have been given W. M. Brewer, district mining engineer, to take the necessary steps to obtain quantities of iron ore for shipment to those plants that have asked for it. Two smelters near Vancouver have undertaken to make the changes required for reduction of the magnetite ores. Under the terms of the act the Department of Mines can expend up to $50,000 in this work.

At a recent meeting of the Trail Reconstruction Board, objection was taken to the marketing in Canada of foreign metals, and representations were made to the Dominion government.

'The Coal and Petroleum Appropriation Act, 1919' is the title of a measure introduced by Hon. T. D. Pattullo, Minister of Mines, during the last session of the Legislature, and has become law. It provides authority for the expenditure of $50,000 in the investigation and exploration of potential oilfields in this Province. The work also will have in view the location and the obtaining of all possible information as to the possibility of developing on Crown lands new coal-producing areas. It is understood that attention first will be directed to the lands of the Peace River district, near the Albertan boundary.

Two measures passed at the last session of the Legislature affect the mining industry in an important manner. One of these provides for the amendment of the Placer Mining Act to permit every free miner, during the continuance of his certificate, to "enter, locate, prospect, and mine for gold and other precious metals and stones" upon Indian reservations. The other amends the Mineral Act to permit holders of free miners' certificates to "enter, locate, prospect, and mine" upon Indian reservations. These amendments do not come into effect until proclaimed law by the Lieutenant-Governor of British Columbia. The Dominion government, it should be explained, is the legally constituted guardian of the Indians, and it may take the position that the Province has no authority to permit miners and prospectors upon reservations. It will be necessary, therefore, before the said proclamation is issued for the Province to come to some understanding with the Federal authorities on the point and this matter already is being taken up by the British Columbian administration with Ottawa.

In the vicinity of the Trail smelter there is a considerable agricultural area, and the owners have been complaining of injury to their crops caused by the smoke from the plant. The petitions received from the farmers resulted in the enactment at the last session of the Legislature of the Industrial Operations Damage Compensation Act. The chief clause of this measure sets out that any company, owning or operating any reduction works or industrial plant, or proposing to acquire or operate any ore reduction works or industrial plant, "may make an agreement with the owner of any land for payment to the owner of compensation for any damage or injury resulting or likely to result to the land, or in respect of its present or future use, from the operation of the ore reduction works or industrial plant." If the company and the land-owner cannot come to an agreement, it is provided that application may be made to the Public Utilities Commission for the fixing of the amount of compensation rightfully due the latter. This, of course, constitutes a recognition of the claims of the farmer, and there is no doubt that it will result in a settlement of the issue between industrial companies and those agriculturists in the Province who have felt themselves aggrieved, but with no means of obtaining redress.

Considerable interest has been aroused by the recent declaration of an initial dividend of 5% by the Belmont Surf Inlet company, operating on Princess Royal island. The amount is $125,000.

The eight-hour working day for metalliferous miners came into force on April 1: 5500 men were affected. The law, which was passed at the session of 1918, provides for eight hours of work to metal miners from bank to bank, and for the same working day for those employed on the surface, the latter's time to commence from the moment they report for duty.

The French Complex Ore Reduction Co., which has a plant near Nelson, designed to experiment in the treatment of the complex ores from this Province, was granted $25,000 by the Provincial government in 1918, the same to be a charge on its assets. Of this amount the Government held back a sum to meet back interest on bonds previously guaranteed by the Province on behalf of the company. Thomas French, the manager, claimed that this seriously handicapped him in the work he has in hand and made such representations to the Mining Committee of the Legislature during the late session, that the Government will release to him $7906, representing the total of the aforesaid interest. Mr. French states that, providing this financial relief is forthcoming without delay, thus obviating unnecessary overhead expense, it would be sufficient to enable him to demonstrate the commercial feasibility of his method of treatment of complex zinc ores. Owing to past delays he states that his expenses have been excessive.

CRIPPLE CREEK, COLORADO

CRESSON RESERVES.—DIVIDENDS.—STRONG LEASES AND ROYALTY.—INCREASED ACTIVITY.

Roads for hauling ore have been cleared of melting snow, and shipments from properties not connected direct by rail are increasing. Dump operators are also returning to work, and the quantity of low-grade ore treated will be much heavier than during the long winter.

The monthly report of the Cresson gives an estimate of ore-reserves as worth $2,431,284. Details are given of two important discoveries: one, known as 812, has been developed a length of 55 ft., showing a width of 22 ft., with grab-samples averaging $29.60 per ton. The new orebody at the 11th level, while not fully developed, promises to be substantial, with grab-samples assaying $54.70 per ton. The ore shipped from the mine in February netted $90,002.

The Portland paid its regular quarterly dividend of 2 cents per share, $60,000, on April 20.——The Vindicator paid its quarterly of 1 cent, $15,000, on April 25.

Prospective lessees have been swarming to the Strong mine every day since it was announced that Owen Roberts, the lessee, would sub-lease, and every available block has been taken. The terms are severe: 25% royalty to the Strong G. M. Co., with 1% war-tax, leaving 74% of net returns to be divided 50-50 between the sub and original lessee. On ore returning $100 net, the sub-lessee therefore would receive but $37.

The Larson lease at the Six Points, and Basket and Luce lease at the American Eagles, mines of Stratton's Cripple Creek M. & D. Co., are shipping 2-oz. ore.

Two Ironclad Hill properties—the Jerry Johnson and Forest Queen—which have been under a snow blockade for three weeks, had teams employed the latter end of last week, loading out ore. The ore-houses at both properties are congested.

At the meeting of the Eagle Ore Co., held at the sampler in this district on April 12, the former officers, headed by G. S. Wood as president and G. A. Stahl, secretary, were re-elected.

Properties in the district are now operated with full complements of men. Lessees are resuming at mines inactive during the winter, and others for more than a year. With further reduction in operating costs by lower prices for explosives and other supplies, the district would become more active than for a long time past.

DURANGO, COLORADO

POWER SHORTAGE.—GENERAL DEVELOPMENT NOTES.

Telluride.—The shortage of power is noticeable in the number of men being laid-off. The Tomboy continues to operate; the Smuggler has its own power-plant, only buying power to operate hoists; the Liberty Bell has shut-down its mill, and will close the mine as soon as sufficient ore is in bins for re-starting the mill when power is again supplied; the Black Bear mine of the Smuggler Union will be the only holding of this company to cut down heavily, although, the Inamo and Perino lease, (Caruthers lease) will not be able to start as was originally intended. Warmer weather now prevails, but not warm enough to fill the reservoirs as rapidly as desired, yet the outlook is favorable for an early return to normal power conditions.

Snowslides still cause some damage, the Bob-Tail slide running and knocking a number of buckets from the Tomboy aerial tram. This slide is peculiar in that it has reformed and run several times this winter. No great damage was sustained. Snow and mudslides again blocked the Rio Grande Southern lines at intervals from March 31 to April 5, but the longest delay was only for one day. At this time of the year, with the rains mudslides are common, and cause numerous delays to ore in transit. The district is now passing through the dull period that precedes the opening of a new season, the usual occurrence. The power shortage has, of course, resulted in the postponement of many activities, the most important of which is that of the Belmont Wagner Mining Company.

Silverton.—Snowslides have caused another blockade, extending from March 31 to April 5. No ore moved on the D. & R. G. lines, and the Silverton Northern was also blocked. The district is quiet, and mining is at a low ebb. The shortage of power will have a more serious effect on Silverton than on other districts, as this is entirely dependent upon current furnished by the Western Colorado Power Co. Crude ore shipments are on the increase, particularly from the Dora, Champion, and Detroit & Colorado properties.

A number of examinations of the workings of the old One Hundred mine indicate a marked interest in the property by outside capital, and many believe that the litigation that has tied it up during the past eight years is nearing settlement, and that the famous producer of former years will be re-opened. The trouble is a contest between the original title-holders and the creditors of the lien-holders of the old One Hundred corporation, the former refusing to co-operate with the creditors. The mine contains large continuous veins of good ore, and shipped large tonnages prior to 1907, during which year operations ceased, owing to the financial panic. Just prior to closing, a mill and tram were erected.

The Highland Mary Leasing Co. has men employed getting ready to ship; the mill is also being overhauled, and it is proposed to work this property on a much larger scale than before. The Highland Mary carries veins of rich ore, especially high in silver.

The D. L. & W. M. & R. Co. suffered a set-back to operations when its blacksmith-shop, compressor-house, and mining machinery were destroyed by fire. The fire started from an overheated stove in the shop and spread rapidly. The damage is estimated at $7000, all of which was covered by insurance. There is no power to run the compressor and operations will be continued by hand-drilling.

The Iowa Tiger mine and mill have had serious set-backs during the past few weeks, owing to machinery troubles. The hoist at the mine broke-down, involving a delay of a few days; but the most important damage was that of the destruction of the mill transformer by lightning, causing a delay of ore treatment for a few weeks. The Iowa-Tiger was fortunate in securing the transformers at the Pride of the West, which are now being installed, and milling will probably be resumed in the near future.

Red Mountain.—This district has been actively developed during the past winter, and the outlook is favorable for continuous and heavy shipping during the coming season. Among the properties that expect to produce are the Guston, Yankee Girl, Robinson, Congress, Barstow, and Silver Bolt.

Animas Forks.—There is marked interest in development of this section, and as an early run-off of snow is expected, the district expects to be listed among the early shippers.

The Animas Forks Consolidated M. & M. Co., and the Gnome Mining Co. have leased their extensive holdings to W. M. Johnston of Animas Forks, with the option of purchase.

Placerville.—During 1918 radium extracted from the ores of Paradox valley totaled 22 grammes. The principal producer is the Standard Chemical Co., which will resume operations on a larger scale in the near future.

O. B. Willmarth, purchaser of radium-bearing ore, operating a reduction plant at Montrose, and who purchases most of the output of the small producers, is investigating the Long Park area with the view of developing several promising prospects.

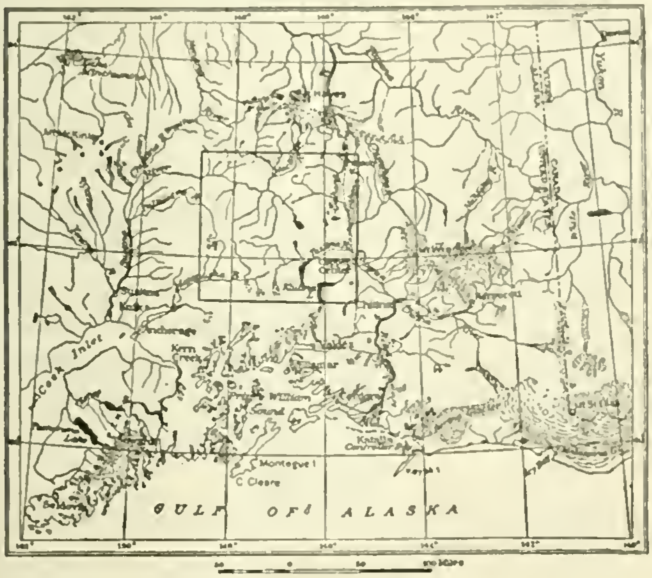
Increased activities in such deposits is indicated by the purchase of two portable prospecting outfits by the Schlesinger company, and the Radium Luminous Metals Co., respectively.

Sawpit.—The Colorado Vanadium Co. is shipping a car of ore daily to the Primos Chemical Co.

THE MINING SUMMARY

ALASKA

Anchorage.—In Bulletin 668 of the U. S. Geological Survey, just issued, the Nelchina—Susitna region is described by Theodore Chapin. Although the area is much more accesible than many parts of the Territory which are far better known, it had up to 1913 been visited relatively little. Little productive mining has been done, and the geology does not encourage the hope of finding extensive placers, yet the wide distribution of alluvial gold indicates considerable mineralization, according to Alfred Brooks in the preface to the publication. It may be that deeply-buried placers exist, but they would have to be rich to meet the operating costs. When the railway is finished to the Matanuska coalfield the region will be readily accessible.



PART OF ALASKA, SHOWING THE NELCHINA—SUSITNA REGION.

Juneau.—Alaska Gastineau in 1918 operated at a loss of $116,565, plus $219,685 for interest on bonds and notes, a total deficit of $336,250. In 1917 there was a surplus of $42,274. There was treated 1,285,445 tons of $1.09 ore, compared with 2,240,346 tons of $1.10 in 1917.

Skagway.—A gold strike that is attracting much attention is reported on the Morley river, 150 miles north-east of this town, and just a few miles south of the international boundary. Morley river runs into Teslin lake. The surface 'dirt' is said to yield 30 to 50 cents. Bedrock has not yet been struck.

ARIZONA

Humboldt.—Consolidated Arizona Smelting produced 720,000 lb. of copper during March, a decrease of 280,000 pounds.

Miami.—The Miami Copper Co.'s profit in 1918 was $5,262,419, of which $3,362,013 was distributed. The output from 2,132,941 tons of ore was 58,407,563 pounds.

Pearce.—High-grade silver ore has been found on the seventh level of the Middlemarch mine, 9 miles west of Pearce. This ore carries 4% copper and 12% zinc, with silver up to 50 oz. per ton. The ore is different from that on the levels above, and much higher grade. On the eighth level there is now 10 ft. of ore running from 2 to 16% copper, as shown in the cross-cut, with high-grade ore still in the face. This ore carries 2 oz. of silver also. The strike is considered important, as showing improved value at depth. The district has had very little development below 300 ft. in depth.

Prescott.—Frank L. Carlisle, of Pittsburgh, has purchased further interests in the Tip Top mine. It is said that he has now practically full ownership.

Concrete foundations for the new 50-ton mill at the Peck mine have been completed. A ball-mill, Wilfley tables, and cyanide-tanks are being erected to treat the 20,000 tons of silver-bearing tailing.

Ray.—During 1918 Ray Consolidated made a profit of $4,803,455, less than half that of 1917. Dividends totaled $5,275,831, a decrease of $1,300,000. The output was 86,919,270 lb., 1,600,000 lb. less than in the previous year. Costs rose from 12.65 to 17.19 cents per pound. There was 3,411,000 tons of 1.613% ore treated.

Superior.—Magma Copper produced 1,002,000 lb. during March, a reduction of 211,000 pounds.

CALIFORNIA

Auburn.—The Yukon Gold Co.'s dredge on the little fork of the American river was robbed of gold amalgam worth $2000 last week.

Downieville.—Good gravel has been found in the Old Miners' mine at Howland Flat in Sierra county. The pay is in two formations—gravel and pipe-clay. The gravel washes freely, but the clay presents difficulties which nothing but machinery will overcome. Miners are being engaged as fast as operations permit.

The Loftus Blue Lead Co. of Los Angeles is piping out the ground on which stands the old town of St. Louis in the northern part of the county. Five shafts were sunk last summer, and prospects warranted the present work. Woodwork of the buildings is being removed preparatory to washing away the stone walls. The tailings go to a restraining-dam.

Dr. H. H. Barrows of Oakland is in the county for the purpose of making an extensive examination of the placers in the northern part, and to investigate the feasibility of working the black sands from the abandoned hydraulic mines. The work will extend over several weeks.

Loeffler brothers of Sierra City have found the vein in a tunnel after spending much time and money. The ore prospects well in free gold and sulphides.

The El Dorado mine near Alleghany is expected to resume operations about May 1.

The Brush Creek mine near the Mountain House, idle for years, will be re-opened early in May.

Jackson.—The fire in the Argonaut has been confined to parts of the 3700 and 4300-ft. levels, and mining will be resumed at an early date. The Kennedy mine adjoining, closed for a time on account of fume, is again in operation.

Keswick.—The Mountain Copper Co. is surveying for a tram from its Iron Mountain and Hornet mines to a point on the Southern Pacific railroad, four miles north of Keswick Junction on the Iron Mountain line and the Southern Pacific. It is reported but not officially confirmed that the company will ship ore by this tram eventually and abandon the Iron Mountain road. It is also said that the tram would save enough in two years to pay for itself.

Melones.—The supervisors of Calaveras county on May 5 will open bids for construction of a new grade from the Melones bridge across the Stanislaus river to the top of the hill on the county road to Angels, a distance of 1½ miles. The county called for bids for the work some time ago, but the figures were too high, the lowest being about $20,000 per mile. The old road from Melones to the top of the hill on the Angels road is very bad and dangerous. The mines in this region will benefit considerably by any improvement to the roads.

Oroville.—In his suggestions for improvement of roads in Butte county, E. B. Wulff, Federal highway engineer, has a list of 25 roads, those that would benefit mining districts being as follows: Oroville-Honcut, 12.3 miles, $92,000; Oroville-Forbestown, 11.5 miles, $40,000; Oroville-Quincy, 30 miles, $178,000; and Pentz-Magalia-Powelton, 35.2 miles, $125,000.

Rutherford.—The White Rock magnesite mine of F. R. Sweasey, of San Francisco, 20 miles east of this place, has been re-opened after several months idleness. The ore is calcined at the mine, and is high in iron, desirable for refractory purposes.

Taylorsville.—The Trask & Coffer Mining Co. has erected a compressor at its mine in Moonlight canyon, adjoining the Engels mine. Developments with a large force will be resumed early in May. L. L. Coffer is manager and Gerald P. Roman superintendent.

COLORADO

Aspen.—The mining outlook for this district is rather discouraging, as the principal silver producer, the Smuggler, has been closed. The pumps have been stopped, and the lower workings are at present flooded with water.

Breckenridge.—The Summit County Metal Mining Association has arranged its headquarters in town here. J. R. Wood is president, and recently addressed the Association on the possibilities of the region.

Durango.—The Durango smelter was shut-down from March 1 to 31, partly owing to a shortage of ore, caused by snowslides on the railroads, also to permit of overhauling the plant. It is again operating three shifts, and receiving a fair supply of ore, although the power shortage in the tributary districts has had the effect of curtailing receipts. The sampling-mill is being remodeled and enlarged. A large crusher is being erected, which will probably double its capacity.

Leadville.—A compromise has been arranged over the wage dispute, miners receiving $4 per shift instead of $3.50 as first suggested by mine-owners.

IDAHO

Adair.—The Montana-Idaho Copper Co. is now working two shifts instead of one. The main tunnel has been driven 4265 ft., where it attained a depth of 1100 ft. A drift started at the 3865-ft. point has been driven 1050 ft. to a depth of 1300 ft. About $70,000 has been spent in operations, and a large sum in equipment, which includes a compressor, water and electric power, and drill-sharpener. The Monitor shaft is 3000 ft. ahead. It will be undercut by 1100 ft., and a depth of 1800 ft. attained from the surface.

Kellogg.—The Caledonia Mining Co. in 1918 had gross receipts amounting to $1,096,776, less $288,077 smelter charges. Mining and shipping cost $160,879 leaving a profit of $647,819. Dividends totaled $937,800. Production was 17,971 tons of ore, containing 6,038,784 lb. lead, 668,784 oz. silver, and 94,326 lb. copper. Mining cost $8.68 per ton. Cash assets exceed liabilities by $445,392. Caledonia pays 1 cent per share, $26,050, on May 5. This makes $130,250 for 1919 and $3,803,300 to date.

Wallace.—Lessees at the Success mine have accumulated 400 tons of ore in two weeks and are operating the mill. The lease is between the 700 and 200-ft. levels. The royalty is 20% on lead and silver and 15% on zinc contents of the ore, and $20 daily for the use of the plant.

There is reported to be a shortage of labor in the Coeur d'Alene region, so the Hercules and other companies that are resuming operations are unable to secure enough men.

Wardner.—Over 100 lessees and employees are extracting ore from the old upper workings of the Bunker Hill & Sullivan and Last Chance mines, which sections the company is not working. The ore is treated at the Co-operative or old Bunker Hill mills.

MICHIGAN

Houghton.—Mass Consolidated is re-timbering its B shaft throughout. This work has been postponed on account of lack of skilled men, now available. Copper production is curtailed 15%.

Copper production of the Calumet & Hecla group in March totaled 9,652,053 lb. Of this, C. & H. contributed 4,592,295; Ahmeek, 1,930,333 lb.; Isle Royale, 1,093,660 lb.; and Osceola, 1,038,204 pounds.

The Stanton properties—Mohawk and Wolverine—produced 1,229,772 and 485,234 lb. of copper, respectively, during March.

The Mohawk mine is estimated to have a life of 26 years, there being over 260,000,000 lb. of copper in ore available. The output so far has been over 169,000,000 lb. The profit on the future metal, based on a 15-cent market, is $13,000,000, equal to $130 per share. The ore averaged 23.7 lb. per ton in 1918, when costs were 14.64 cents.

MISSOURI

Joplin.—Concentrate production of the Tri-State region last week was as under:

State	Blende, tons	Calamine, tons	Lead, tons	Value
Kansas	1,078	...	89	$47,861
Missouri	1,223	252	52	......
Oklahoma	5,443	...	833	267,279
Total	7,744	252	974	$370,848
Previous week	7,616	852	1,576	417,555
Average per ton	$39	$27	$60	......
Previous average	39	26	60	......

The Joplin 'News Herald' of April 20 contains a special mining section covering operations in this region.

MONTANA

Great Falls.—The Anaconda company announced on April 18 that it is preparing to blow-in a furnace for the manufacture of calcium carbide, using one of the five furnaces built last year for ferro-manganese. The company is now operating a lime-kiln at its quarries at Albright. The first run will be to make 25 to 30 tons of calcium carbide to test its quality. If it is of good quality, an additional furnace will be blown-in, and the idea is to manufacture from 50 to 100 tons of carbide daily. The carbide will be pressed and sealed in cans, each of 100-lb. capacity. The company recently sold 125 tons of ferro-manganese made last year, when it produced 1000 tons, nearly all of which is now stored at the plant. It is stated that the outlook for marketing it is growing brighter, according to the Anaconda 'Standard.'

In Bulletin 691-E of the U. S. Geological Survey, just issued, oil and gas geology of the Birch Creek-Sun River area of north-western Montana are discussed by Eugene Stebinger. The area described lies adjacent to the front range of the Rocky Mountains, and is part of a large region in the Northern Great plains of the United States and Canada that seems to deserve consideration as prospective territory for oil and gas development. The outcrops of the Cretaceous formations afford unquestionable evidence of being petroliferous, so that drilling in places of favorable structure, such as on well-developed domes or anticlines, seems to offer a reasonable chance of success. Random drilling so far has been uniformly unsuccessful.

MONTANA, SHOWING POSITION OF BIRCH CREEK-SUN RIVER AREA.

NEVADA

Austin.—Shipping ore has been opened by two tunnels in the Austin Nevada Consolidated, and a new orebody exposed in a deep gulch west of the main lateral. At point of discovery the vein assays $10 gold, with the drift showing no sign of the walls. The main tunnel is advancing rapidly to cut extensions of the Panamint, Frost, Curtis, and other famous veins. The general manager, H. G. Richardson, proposes to start shipments of high-grade gold-silver ore in a few weeks. A mill-site has been picked out near the portal of the main tunnel, which has been driven into Lander hill for approximately 750 feet.

Las Vegas.—The Eldorado Gold Mining Syndicate has been organized with a capital of 1,000,000, $1 shares by H. L. Powers and others, to supply water for all the mines in the Canyon district. It is proposed to erect a plant on the Colorado river, pump water 7 miles up the canyon, build a mill, and treat custom ores.

Rochester.—The Nevada Packard treated 2868 tons of ore during March. Extraction was 91.3%. Milling costs decreased 6%. A dividend of 2 cents per share was paid on April 20. This amounts to $23,292.

The Rochester Nevada Silver Mines Co. treated 168 tons daily of $11 ore in March.

Virginia City.—According to Whitman Symmes, the United Comstock Pumping Association has made an agreement with the Truckee River General Electric Co. whereby the debt of $398,000 owed the latter for power for pumping at the mines is practically nullified. The Pumping Association agrees to buy power in future in amount equal to its present indebtedness, this then to be entirely canceled without cost to it. Payments made each month for current power bills will be deducted from past indebtedness.

Willard.—It is said that this old boom gold camp of 1915 is showing signs of revival. It is 9 miles north-east of Lovelock in Pershing county. J. H. Borland, J. J. Garnier, J. Fant, W. Opperman, and several others are doing some work.

OREGON

Baker.—The White Swan gold mine, 12 miles east of here, has been acquired under bond from the Susan D. Mines Co. by H. R. Smalley and others of Spokane. The mine has been full of water since 1904.

UTAH

Alta.—Mine-owners are complaining about the lack of assistance given for road building by the County Commissioners. The road is in such bad condition that ore can only be moved with difficulty.

Green River.—The Shale Products Co. is selecting a site near this place for a plant in which to treat its shale by the Jenson process. Willard Funk of Salt Lake City is largely interested.

The Homestake Gold Placer Mining Co. has been organized in Utah by W. R. Barker and others of McGill, Nevada, to develop placer ground along the Green river in the Uintah basin. The gold-bearing material is said to be black sands, 'extremely rich' in gold.

Park City.—The Silver King Consolidated has purchased the Haneter ranch of 75 acres at the mouth of the Spiro tunnel now in nearly 10,000 ft. This land will give the company plenty of space for dumps, ore-bins, railroad spurs, mill, and for residue disposal.

Tintic.—The Emerald Mining Co. reports encouraging indications on the 1000-ft. level, and it is considered that the quartz formation in which ore was mined at 600 ft. is nearby.

CANADA

British Columbia

Anyox.—The Granby Consolidated smelter resumed operations on April 4, having been idle since March 2. Men to take the places of those who left last month were obtained in Vancouver and elsewhere in the Province, those who received and accepted or rejected applications giving preference to returned soldiers. The latter, therefore, are largely represented at Anyox at present. F. M. Sylvester, managing director of the company, made the announcement that the new by-product coking-ovens at Anyox will be opened early in June.

Franklin.—The Maple Leaf mine in the Boundary district is to have a small smelter to treat its ore. The furnace is being made at Grand Forks, and will have a capacity of 50 tons per day. The furnace is 44 in. diameter and is of cupola type. A 35-hp. gasoline engine will be used to drive the blower. The ore contains copper and silver.

Kamloops.—A road between Princeton and the Aspen Grove mining camp is to be opened by the Provincial government this season. It is known as the One-Mile road, and will shorten the distance between Princeton and Merritt by 17 miles.

Princeton.—Construction of the branch railway to Cooper Mountain for the Canada Copper Corporation has received a temporary check, as 300 laborers employed by the contractors downed tools. They claim that they were asked to work 10 hours at the same wages as was given for 9 hours. Now they want an 8-hour day and a fixed wage of 50 cents per hour, or $4 per day. The strikers are orderly, no trouble having been experienced at Princeton or Allenby, the communities nearest to the mining camp.

Trail.—Ores and concentrates weighing 96,542 long tons have been received at the Consolidated M. & S. plant here during the first three months of the current year. A comparison is shown below. At present the management is not seeking ores of any kind, none being accepted from the

United States. About 85% of the current receipts are from the company's own properties. To the present date only 60 outside properties have shipped to Trail this year.

Month	1917	1918	1919
January	36,570	27,404	35,283
February	40,967	33,989	30,450
March	42,949	41,725	30,809
Total tons	120,486	103,118	96,542

Ontario

Boston Creek.—Three claims of W. Arnold and J. A. Hughes, adjoining the Cotter, itself next to the Miller Independence, have been optioned to Mr. Savage of Buffalo.

Cobalt.—Kerr Lake pays 25 cents per share, $150,000, on June 16. This makes $300,000 for 1919. Kerr Lake produced 104,101 oz. of silver during March, equal to normal.

Nipissing yielded silver worth $261,158 during March, extracted from 208 tons of high-grade and 6962 tons of low-grade ores. The refinery shipped 802,698 oz., partly custom metal. Underground operations were satisfactory everywhere.

Good ore continues to be opened and bagged in the Advance, and 33-oz. ore is being put on the dumps. The company contemplates erection of a 75-ton mill.

It is rumored that there is friction between the Beaver and Temiskaming companies. There are several points in dispute, but the main one concerns ore extracted from the upper workings, containing about 50,000 oz. of silver. These companies both sank shafts to 1600 ft. through the diabase sill to the lower contact. The Beaver met with encouraging results, but the Temiskaming did not.

Kirkland Lake.—The Lake Shore company distributed $50,000 on May 1, bringing the total to $150,000.

The Teck-Hughes gold mine produced 2261 tons of $9.70 ore during March.

Porcupine.—Men are arriving in large numbers at all the goldfields in northern Ontario, and one by one the properties closed are being re-opened. It is expected that the Dome Mines company will require 500 men by summer.

Sudbury.—The Mond Nickel Co. has reduced operations at its Worthington and Levack mines, also at its smelter at Coniston, from three to one shifts per day. The International Nickel Co. is also at about third capacity. International pays a dividend of $1.50 per preferred share on May 1. This is equal to $133,689, and is the same as that paid on February 1.

MEXICO

Chihuahua

Parral.—On Sunday, April 20, Villa and his army fought their way into this centre. He announced that none of the mining properties would be molested, but is said to be renewing demands for taxes for protection offered.

Jalisco

Guadalajara.—During the last week in March, President Carranza attended the formal opening of the first section—25 miles—of the railroad from Guadalajara to the Pacific port of Chamela. This line starts from near Ameca on the Mexican Central, and runs west from Guadalajara to Cocutla.

Sonora

Cananea.—Greene Cananea has discharged 700 additional men. To help these to other points, the company chartered a special train.

El Tigre.—The Lucky Tiger-Combination Gold Mining Co. continues to pay dividends. The last was on March 20, 1919, when 10 cents per share was distributed. This amounted to $214,601, and makes $5,201,955 to date.

PERSONAL

Note. The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Morton Webber is here.

Oliver E. Jager is at Butte.

Henry M. Howe has gone to Europe.

F. G. Stevens has returned from Mexico to Toronto.

C. L. Beckwith, of Phoenix, is visiting northern California.

Arthur J. Hoskin, of Denver, was in the De Beque oil-shale district last week.

Frederick H. Minard has moved from 111 Broadway to 21 East 40th street, New York.

James F. Kemp, **Horace V. Winchell**, and **Charles K. Leith** are at Butte as experts in the Elm Orlu case.

F. W. Bradley has gone to Kellogg, Idaho, and from there to Juneau, Alaska, on a periodical inspection.

Raymond Brooks is in charge of the Benson mines, in St. Lawrence county, New York, succeeding **W. D. B. Motter, Jr.**

H. C. Dudley who held a commission in the 36th Engineers, in France, was here last week on his way from Arizona.

F. W. Sherman, who designed and constructed the Hackberry mill at Chloride, Arizona, has resigned as superintendent.

Charles W. Whitley, for many years general manager of the American Smelting & Refining Company's plants in Utah, has been promoted to the position of vice-president.

A. D. Brokaw, **A. F. Dixon**, **L. G. Donnelly**, **A. H. Garner**, and **H. H. McKee**, geologists and petroleum engineers, announce a partnership, with offices at 120 Broadway, New York.

A. B. Emery, general manager of the Messina copper mine, in the Transvaal, has left San Francisco and will go to Seattle, Butte, and Salt Lake City, on his return to London.

E. G. Banks, superintendent for the Waihi Gold Mining Co., New Zealand, is here on his way to London. He is visiting several American mining centres in order to study the flotation of gold and silver ores.

An Association of Members of American National Engineering Societies in Cuba has been formed "to foster the interests of the various national engineering societies represented on the island." **T. Carlile Ulbright** is secretary of the organization, which has its office at Havana.

Edwin C. Holden, general manager for the Davison Sulphur & Phosphate Co., having brought the Carlota mine, in the province of Santa Clara, Cuba, to a shipping stage, is moving to the headquarters of the company at Baltimore. **Chester A. Fulton**, superintendent, succeeds him as manager in Cuba.

The Pittsburgh chapter of the American Association of Engineers has a secretary. This is the first chapter outside of national headquarters at Chicago to have a secretary giving all of his time to the work of the Association. F. K N. Thatcher has been selected for the position, and will have an office at 1312 Fulton Bdg., Pittsburgh.

'Business Law for Engineers', an evening lecture course, was started on April 21, at the San Francisco Public Library, under the direction of the Extension Division of the University of California. The series will include 30 lectures by Eugene G. McCann, a member of the California bar, who has had seven years' experience in engineering work in this State.

THE METAL MARKET

METAL PRICES

San Francisco, April 29

Aluminum-dust, cents per pound	50—60
Antimony, cents per pound........	8
Copper, electrolytic, cents per pound.	15½
Lead, pig, cents per pound.........	5¼—6¼
Platinum, per ounce	$100
Quicksilver, per flask of 75 lb......	$75
Spelter, cents per pound...........	8
Zinc-dust, cents per pound..........	12½

EASTERN METAL MARKET

(By wire from New York)

April 29.—Copper is inactive but steady. Lead is dull and unchanged. Spelter is stagnant though firm.

SILVER

Below are given official (not Government) quotations, in cents per ounce, of silver 999 fine. In order to make prompt settlements with smelters and brokers, producers allow a discount from the maximum fixed price of $1.01½, hence the lower price. The Government has not fixed the general market price at $1, but will pay this price (as from April 23, 1918) for all silver purchased by it. The equivalent of dollar silver (1000 fine) in British currency is 46.85 pence per ounce (925 fine), calculated at the normal rate of exchange. On August 15, 1918, the Treasury announced that the maximum price was fixed at $1.01½ per ounce. The British government fixed a maximum at 49½ pence, on September 2, but on November 12 this was changed to 48¾, on December 13 to 48 7/16, and on February 20 to 47¾ pence. On March 25, on account of the low rate of exchange, the London price was adjusted, with a minimum of 95 cents, resulting in daily fluctuations.

The silver coin and bullion in India is increasing, as on March 31 it totaled 3235 lacs of rupees ($103,520,000), against 2563 lacs ($82,016,000) on the 15th. At the same time the silver coin and bullion out of India decreased to 504 lacs ($16,128,000) from 1201 lacs ($38,432,000). The value of the gold in and out of that country remained stationary. The value of coins minted during the last week of March was 149 lacs ($4,768,000).

The stock of silver at Shanghai is increasing, the total at the end of March being 30,750,000 oz. and 17,900,000 dollars (50 cents).

Silver production of the principal mines at Cobalt, Ontario, in 1918, was as follows, with the cost:

Mine	Ounces	Cost per ounce
Beaver	385,042	...
Buffalo	767,740	...
Coniagas	974,204	33.87
La Rose	228,556	87.17
McKinley-Darragh-Savage	904,543	68.42
Mining Corporation	1,708,252	60.96
Nipissing	3,701,416	39.02
Trethewey	269,000	54.00

TIN

Prices in New York, in cents per pound. The monthly averages in 1918 are nominal. On December 3 the War Industries Board fixed the price to consumers and jobbers at 72½c. f.o.b. Chicago and Eastern points, and 71½c. on the Pacific Coast. This will continue until the U. S. Steel Products Co.'s stock is consumed.

Eastern Metal Market

New York, April 23.

All the non-ferrous metals are in poor demand, with sales few and small; prices, however, are just about holding their own. The general slump in these markets is attributed by many to the steel price muddle.

Antimony is quiet and slightly lower.

Copper is very quiet, with prices only slightly lower.

Lead is decidedly inactive, but prices are holding firm.

Tin has no market, and conditions are unchanged.

Zinc is in poor demand, and quotations have fallen moderately.

ANTIMONY

There is very little change in the market which is quoted at 6.50 to 6.62½c., New York, duty paid, for wholesale lots for early delivery. The market is quiet.

ALUMINUM

No. 1 virgin metal, 98 to 99% pure, is slightly higher at 30 to 32c. per lb. for prompt and early delivery. Re-melt metal of the same purity is about 2c. less per pound.

COPPER

The market continues in the quiet, inactive condition noted a week ago. Demand has fallen off decidedly, and sales have been few. This state of affairs is regarded as normal by some producers. They contend that the fairly heavy buying of a few weeks ago entirely satisfied consumers' needs for April and early May, therefore buying now would be light. There is little desire to purchase beyond immediate needs, and still less inclination by sellers to sell for extended future delivery. The price fiasco in the steel industry has had its effect on copper and other metals. It is a fact that one fairly large buyer of copper intended to place orders about the time that the Director General of Railroads declined to accept the steel prices, but because of this he refused to pursue his original intention and so far as known has not bought yet. Electrolytic copper is quoted at about 15.12½c., New York, for early delivery, with Lake copper nominal at 15.37½ to 15.50c. Large producers are asking 15.25 to 15.37½c., New York, for electrolytic copper, with small interests willing to shade this from ⅛ to ¼ cent.

IRON AND STEEL

It has not been generally recognized that an open market in steel really exists because widespread and sensational price-cutting has not been in evidence. The industry has been limiting operations to cover incoming business only, and there has been considerable shutting-down of steel plants and banking of blast-furnaces. A 50% operation is reported for independent companies with the U. S. Steel Corporation on about a 70% basis in the Chicago and 60% in the Pittsburgh district.

LEAD

There has been no demand in the past week and the market continues lifeless. It is believed, however, that despite the inactivity and lack of buying the metal cannot be bought below the present quotations of 4.70c., St. Louis, or 4.95c., New York, obtaining in the outside market. The American Smelting & Refining Co. continues its asking-price at 5c., New York, and 4.70c., St. Louis. The market is regarded by most sellers as firm. A revival in demand is not looked-for until buying in steel has been resumed.

TIN

The question as to how fast the U. S. Steel Products Co. is disposing of its allocated metal is the only interesting question before traders, but efforts to learn about the present stocks have all been unavailable. It is hoped that an open market will prevail after June 1, but there is no certainty regarding this. The market continues absolutely dead, with no transactions reported. The only metal changing hands is that passing from this company to consumers at 72.50c. per lb., the fixed Government price. American tin is unavailable, having been withdrawn from the market. The quotation for future shipment from the Far East is about 49c. per lb. for shipments to start after import restrictions have been removed. There has been a little buying under these conditions, but only a little. If restrictions should be removed on June 1, this would mean that such tin so purchased would not reach the Pacific Coast until about September 1.

ZINC

One large producer calls the market "sick". There is absolutely no demand of any consequence, and prices have again fallen slightly. Prime Western for early delivery is quoted at 6.05c., St. Louis, or 6.40c., New York, with futures slightly higher. A sale for June delivery is reported at 6.15c., St. Louis. About 100 tons has been sold for export to Australia, and Japan is today inquiring for some for export to that country. While the amounts involved are small, as affecting the market, the interesting fact is that both Australia and Japan are producers and exporters of the metal. The latter country is now sending zinc to England. Grade A zinc is offered at 6.75c., with brass special for prompt delivery held at about 6.15c., St. Louis.

ORES

Manganese: The Indian manganese ore, available at 55c. per unit seaboard last week, has not been sold.

Molybdenum: The market is quiet and prices are nominal at 80 to 85 cents per lb. of MoS_2 in regular concentrate.

Tungsten: There is no change in conditions and very little demand. There has also been no fair test of the market. Quotations are being made in some quarters at $10 to $12 per unit for best grades of scheelite, but these are probably nominal. There has been no fair test of the ferro market.

Book Review

Galvanizing and Tinning. By W. T. Flanders. Pp. 312, ill., index. David Williams Co., New York. For sale by 'Mining and Scientific Press', San Francisco. Price, $4.

This is a complete revision of the author's earlier work on the same subjects. In this he has had the assistance of several men that are authorities on certain special processes. The first chapter contains a general discussion of corrosion and its prevention, and then comes a description of hot-galvanizing plant and equipment, including pyrometers. The author then considers materials used in galvanizing, also preparing work for galvanizing, including pickling, water-rolling, tumbling, and sand-blasting. Then come several chapters devoted directly to the hot-galvanizing process. The Schoop 'metal-spray' process is then considered. Then come several chapters on tinning, and following that a discussion of electro-galvanizing. Sherardizing is then considered. The final chapter is devoted to galvanizing specifications and tests. The book is well-illustrated and will be of value to anyone interested in the subjects discussed, whether as a manufacturer or as a consumer of galvanized and tinned products.

EDITORIAL

GEOPHONE is the name of a most interesting device, a description of which will be found upon another page of this issue. It can be used to detect the position whence sound comes underground, so that it will be useful in mine accidents and fires. This is one of the devices invented during the War for use in sapping operations.

PROCEEDINGS against the Minerals Separation company before the Federal Trade Commission have been supplemented by the filing of a brief on certain jurisdictional points by the American Mining Congress, through its counsel, Messrs. Pershing, Nye, Frye & Tallmadge, of Denver. This brief takes strong ground in support of the Commission in its charges, filed last November, against Minerals Separation, Ltd.

SENATOR PHELAN, in his apparent anxiety to keep in the public eye, is playing the Hearst game. First he tries to scare the people of California with his Japanese picture-bride story; then he concocts a weird tale of British efforts to control the entire oil industry of California. Hearst features these irresponsible yarns and repeats the oil story even after it has been categorically denied. In the same issue of his paper we find a cablegram stating that the British are making a $250 automobile out of "slag, clinker, and sawdust, and covered with a metal solution." The metal must resemble that famous alloy, Hearst brass.

PEACE is in sight. The rise in quotations on the Stock Exchange reflects the cheering prospect. The German delegates may fuss and fume; they may bluff and bluster; but they will sign. Germany's naval and military powers are shattered; her government knows that to refuse to come to a settlement is futile; the terms are more nearly just than she would have imposed in the event of herself emerging victorious in the War; the threat of a relapse to bolshevist chaos will not intimidate the Peace Conference. Italy's dispute with her Allies does not affect the settlement with Germany, for the Fiume controversy is part of the settlement to be made not with Germany but with Austria-Hungary. We are going to celebrate peace soon and thereby set the seal on the Armistice.

DISCUSSION this week includes a timely letter from Mr. Walter E. Gaby on the geology of the Yerington mining district, a subject on which he is particularly well qualified to speak. He joins with Mr. Adolph Knopf in emphasizing the importance of fissuring upon the distribution of the ore, and the consequent importance of a detailed study of the system of fissures. Mr. F. C. Brown is again a welcome contributor. He discusses 'Invention' and manages to infuse a dry subject with religious poetry. We know that his seriously thoughtful way of looking at things, even technical subjects, pleases many of our readers, as it does us. Mr. John Randall, like Mr. Brown, uses allegory to explain his ideas. His letter on 'The Status of Gold' comes as an appropriate sequel to the series of contributions published by us on this subject during the last three or four months.

PALE and almost fainting with emotion, we are told, was Count von Brockdorff-Rantzau, the head of the German delegation, when he presented the credentials of his party to M. Jules Cambon, the chairman of the Peace Commission at Paris. Life is full of compensations, if one but waits. M. Cambon was the French ambassador to Berlin at the time when the Prussian began his onslaught upon civilization and many of our readers will recall the scurvy manner in which the Germans treated him, threatening and insulting him and his staff while on their way out of Germany, refusing even to give them any food in the course of their journey by rail from Berlin to Copenhagen, and compelling them to pay in cold cash for the cost of the special train on which they traveled. That was on August 5, 1914. On May 2, 1919, the German representatives upon arrival in Paris, to sign a humiliating peace, appeared before M. Cambon "pale and almost fainting with emotion."

FURTHER installments of the Alien Property Custodian's report on the workings of the German metal combination are appearing in our pages. The last will be published next week, when we shall offer a few supplementary remarks. We allude to the subject now in order to warn the reader against the attempt, appearing on page 638, to explain the flotation process. Mr. A. Mitchell Palmer, or Mr. Francis P. Garvan, or whoever is directly responsible for the report issued from the office of the Alien Property Custodian, would have been wise to submit anything written on the technique of flotation to somebody versed in the subject or else abstain from all attempts to instruct the public on the matter. Only a thorough knowledge of a technical subject will enable one to explain it to the non-technical; a popular description when offered by an amateur is about as effective as the ointment that went down Aaron's beard, even unto the skirts of his garment: it only made a mess!

The Geology of the Divide District

In this issue we publish a short article, by Mr. Frank L. Sizer, on the Divide district and the boom that followed the uncovering of a large orebody in the Tonopah Divide mine. He is careful not to commit himself too deeply, in the absence of the necessary evidence, but he brings out clearly the fact that the distribution of ore, and of two kinds of ore, is dependent upon the relation of two distinct systems of fissuring. Apparently the extent and character of the zone of secondary enrichment, or intense concentration, has yet to be ascertained by further exploration. Our own experience permits us to hazard the suggestion that, in deciding upon the influence of subordinate ore-bearing fractures, it is important to discriminate between 'droppers' and 'robbers', between those that enrich and those that impoverish. While referring to this part of Nevada, we take the opportunity to correct a possible misapprehension caused by an erroneous paragraph in a recent issue of the San Francisco 'Chronicle', in which it was stated that the Divide, or Gold Mountain, district "has been unfavorably reported on by the U. S. Geological Survey." The Director of the Survey, Mr. George Otis Smith, informs us that Mr. J. E. Spurr visited the district in 1902 and made merely an incidental mention of Gold Mountain, in connection with his geological work at Tonopah. The paragraph runs as follows: "The Gold Mountain district lies nearly half-way between Tonopah and Klondike and is in the stage of development. Gold mountain is composed of rhyolite, both in solid flows and in consolidated tuffs and breccias. Through these rhyolites run strong and persistent veins of quarts and delicately colored chalcedony veins, sometimes containing pyrite. In some parts of these veins, especially in the oxidized portions, rich assays have been obtained. The mineralization is probably of a later date than that which has produced the ores at Tonopah, but may be of the same age as those at Klondike, although the ore deposits themselves are of a different character." In Bulletin No. 308, by S. H. Ball, published in 1907, the district now known as Divide is briefly mentioned. It is stated: "The Kanakee Mining Company has a 100-foot shaft, which passes through rhyolite, tuffs, and breccia. Dense quartz fills the interstices of breccia and also occurs in veins. The ore is free-milling and is said to run about $30 in gold and silver per ton, although assay-returns have reached $317." Then follows a quotation from Mr. Spurr's paragraph as cited above. In his report on the Tonopah district, published by the Survey in 1905, Mr. Spurr, in referring to a certain group of comparatively unproductive veins at Tonopah, states: "The mineralization is then probably the same in time, nature, and origin as that at Gold Mountain, four miles south of Tonopah, and very likely similar to that in the newly discovered camp of Goldfield, about 28 miles south of Tonopah." The foregoing are the only references to the Divide district that have appeared in the reports of the U. S. Geological Survey, and there is nothing in them to justify the sweeping assertion of the 'Chronicle' that the district "has been unfavorably reported on." The fact that the veins at Divide were compared or correlated by Mr. Spurr, in the passage just quoted, with a set of rather unproductive veins at Tonopah might perhaps in itself be interpreted by some readers as indicating little promise for Divide, but the inclusion of Goldfield in the comparison negatives this suggestion, and Mr. Spurr himself nowhere states that veins belonging to the same period as the later and less productive veins at Tonopah may not in other districts be rich. We are glad to say this much in fairness to the Geological Survey.

President of the University

Just now a very proper interest is being taken, not only in California but farther afield, in the selection of a president for the University of California. The present incumbent, Mr. Benjamin Ide Wheeler, retires in July, after twenty years of distinguished service, marred near its end by an irretrievable blunder. Mr. Wheeler was one of the exchange professors sent to Berlin, on the Kaiser's initiative, and unfortunately while in the precincts of Potsdam he was so overcome by the condescension of the great, including familiar converse with the All Highest, that he returned home an admirer of the Prussian king and a friend of Germany. When the War began in Europe he was outspoken in behalf of the country against which the United States declared war on April 6, 1917. In short, he made the biggest blunder that a clever man could make in the second decade of the 20th century. So his retirement is logical. It will be difficult, however, to replace him, for in scholarship, in administration, and in his public appearances as a spokesman for the University, he played his part well. The Regents have appointed a committee from among themselves to select a new president. Their task is one of much difficulty and heavy responsibility. The annual budget of the University of California calls for the sum of $3,500,000 and its student body numbers 8500. The presidency of our State University is the most influential position west of the Mississippi river; it is more important that the governorship or the senatorship in any State or all the States within that geographic limit; it represents the intellectual leadership of the Pacific Coast. Therefore the choice, soon to be made, is of great interest not only in academic circles but to the public. Our readers, many of whom are professional men and college graduates, are keenly aware of the importance of choosing the right man. What sort of a man should he be? First, he must be a scholar and a gentleman; he must be a man of vision; next he must be an executive and an administrator; he ought to possess tact and be a man of the world in order to deal successfully with the representatives of the community that supports the University, notably the State legislature, which apportions the funds needed for its work; he should be able to make a good speech and thereby interpret scholastic ideals to the public; if he be a man of fine presence—looking like 'presidential timber'—so much the better; finally, in order to do his work well and to continue to do it for a period long enough to establish an effective tradition, he ought to be physically vigorous and comparatively young. Indeed, he is assumed to resemble the Admirable Crichton. The abilities and the qualities, mental and physical, that are demanded are those of a splendid specimen of the *genus homo* and the *species sapiens*; he is expected to be a 100% man. It being unlikely that the perfect specimen can be found, which of the qualifications are essential and which are accessory? Among those mentioned for the appointment are a financial comptroller, a Cabinet minister, a paleontologist, and an economist with military experience. The University depends on the goodwill of the Legislature, therefore a man of engaging and persuasive manners is useful. The University is a big business institution, therefore financial acumen is an asset in its president. These factors cause stress to be laid upon abilities that are not common among scholars; indeed, many people insist that the president must be a business man, with some scholastic attainments, of course, but certainly much more of a man of the world than merely an inspiring teacher. It is true, universities have become business enterprises and public utilities requiring popular support, legislative approval, and organized publicity. There appears a danger that the more they approach the ideals of successful business the less they are likely to express the much higher ideals of mental and spiritual progress. At the present moment four important universities are seeking new chiefs. One would suppose that among the deans of faculties there would be found the necessary supply of college presidents, but it is not so, because the combination of the necessary qualities is rare. A tendency has developed, therefore, as between a scholar with little business training and an administrator not eminently a scholar, to select the man who can best represent a university in its relations with the public, and with the Legislature, if it be a State institution, or, if not, with such of the rich as have an inclination to play the part of benefactor. We venture to suggest that the begging for money can be done, in some measure, by the regents and that the lobbying is best done by the comptroller, not by the president. A university, especially a State university, should be a focus of intellectual activities, a centre of scientific research, a seat of true learning; it should be, as Huxley said, "a fortress of the higher life of the nation." Neither the number of the students nor the beauty of the buildings makes the university. Indeed, the generosity of Mrs. Hearst in providing money for the construction of white palaces at Berkeley has been negatived in large measure by the pestilential activity of the yellow journalist, her son, whose newspapers, in San Francisco and Los Angeles, have countermined the higher education of the University itself. As Huxley said, at the opening of Johns Hopkins University, 43 years ago, "administrators of educational funds have sometimes made a palace and called it a university." Not buildings, but men; not endowments, but teachers, make a university. It were better to spend less money on handsome structures and beautiful gardens, so that the real makers of the university, namely, the members of its faculty, were better paid; so that the least of them were paid better than a hod-carrier. Agassiz, it will be remembered, said that a university is a professor at one end of a log and a student at the other. The University is not a glorified department store of odds and ends of knowledge, it is "a place where moral worth and intellectual clearness are cherished." So said the great philosopher of the last century, himself an educator of the highest type and the widest usefulness. Therefore we venture to say for the mining profession, in which so many of the graduates from Berkeley now hold a distinguished position, that we hope the need for administrative or executive ability will not be permitted to override the supreme need for selecting as president of the University of California a man of high character and wide vision, an exponent of human aspirations and an interpreter of American ideals, a man of courage and of conviction, a scholar and a gentleman.

The Cost of High Living

Much of the high cost of living is the consequence of high living; it is the extravagance of the rich that makes life difficult for the average citizen. The industrial prosperity due to the War, the fortunes easily made by profiteering, and the successful winnings of stock-exchange gamblers have greatly increased the number of those with more money than sense and with more love for extravagance than for comfort. For these reasons we do not regret to note the incidence of the new luxury tax, which imposes a Federal tax of 10% on retail prices in excess of the amounts specified by law. The Retail Dry Goods Association in San Francisco is said to have collected 100,000 protests against this sumptuary enactment, and the reason is obvious: it will restrict the careless spending of money for high-priced articles. When, however, we read the list of retail prices in excess of which the tax is levied, we find ourselves within the limit except for a hat on which we paid a war price six months ago, and we do not expect to do it again, law or no law. On the other hand the taxation of women's hats in excess of $15 incites no violent objection on our part; being a high-minded patriot we accept it without demur. Indeed, this luxury tax may well provoke a smile from the professional man, from those who work for their living; it is no terrible imposition, but a reasonable check on those who, like drunken sailors, spend their money heedlessly. "Let the galled jade wince, our withers are unwrung." It is about time to call a halt on the orgy of extravagance that has disgraced our larger city communities during the very time when brave men were sacrificing everything in a great cause. The spread of education and the general interest in social economics are bound to bring about some serious thinking on the subject of unnecessary extravagance in living; and with serious thought will come organized opposition, such as the new law, to ways of living that make it hard for those unable to meet the artificial prices created by spendthrifts. It is commonly said that it is none of our businesss how a man spends his money and it is also said that such spending stimulates trade and is therefore a good thing for the community. Such ideas are mistaken. The acts of a citizen in an organized community do concern the community if they interfere with the welfare of a large number of other citizens; the lavish spending of money does affect others injuriously in that it creates fictitious prices and thereby renders the cost of living more burdensome for others. The man that gives a big tip in a restaurant renders it difficult for his fellow, unable or unwilling to pay so much for servility, to obtain proper service. The people that buy the most expensive things without discrimination are making it hard for those whose purses are not illimitable. Today even the cost of most things is high largely because we have in this community, for example, so large a number of persons eager to obtain what they want regardless of its price. The luxury tax by its levy upon excessive prices will check the sale of unnecessarily costly articles, because no man or woman likes to pay a tax, whether large or small. The dry-goods establishments will soon adapt themselves to the new conditions and incidentally will be less able to foster a kind of sumptuary drunkenness that has been at least as injurious to the community as excessive alcoholism. We sympathize with teachers as a class, with the professors in the colleges and the instructors in the schools, because they not only are underpaid, having regard to the pre-eminently valuable character of their work, but because life has been made harder for them by reason of the reckless spending of a far less worthy type of men and women—the idle rich. The cost of everything, even in university communities, has been pushed to prohibitive prices by the careless spending of people without any serious purpose in life. Moreover, the drunken sailor's kind of spending, such as characterizes the successful stock-broker or the fortunate profiteer, breeds parasites innumerable, because every time money is given in excess of the service rendered it incites men to hang around the wild spenders in the hope of getting something for nothing, or next to nothing. Every city contains thousands of men, many of them young and vigorous, that are idle and vicious, simply because they can pick up a fairly good living by standing where the millionaire's money is being splashed about. Such extravagances and stupidity foster social unrest, naturally; a hard-working carpenter or a steady-going tailor, with a family to support, may be pardoned for feeling the injustice to him of a social convention that condones the spending of what to him is a month's wages by an idle man on a luncheon at a restaurant or the careless throwing of a tip to a lackey that would give food and medicine to a sick child for several weeks. The injustices of life are many, and many of them are inevitable; to these the sensible man reconciles himself; but there is much in our social system, notably its crass materialism, that calls for attention, not only for the sake of the less fortunate, who are the more numerous, but for the sake of the foolish minority of persons not sufficiently educated to know how to spend money decently. Unfortunately a bad example is set in the highest quarters. The extravagance of the Government has become proverbial. We are asked to buy War Saving Stamps and thereby promote "wise buying, intelligent saving, and good citizenship"; yet every mail is loaded with printed matter issued from Government departments, much of it entirely wasted and often in duplicate. One Congressman, hoping to become a Governor of his State, spent $288,000 of public money in sending a parcel of books to each elector; he sent 640,000 parcels on one day, saving himself 45 cents of postage per package. In one year another Congressman sent out under frank one-fortieth of the entire mail matter of the country. It was stated recently in Congress that a Congressman caused attacks on preparedness to be printed at the Bureau of Printing, and then distributed them under frank, with franked envelopes enclosed, so that each recipient could re-mail them to other individuals. We are threatened with a flood of projects for giving a helping hand to everybody. The Government departments are sending commissions to Europe of which it need only be said that they will eat luncheons, make speeches, see the sights in the war-zone, and return safely. A commission organized by the U. S. Bureau of Mines, and including technical men brought all the way from California, was sent to Europe for the purpose of examining the iron districts of Lorraine when another commission of mining-engineer officers from the 27th Regiment was returning from the same region, having just finished a similar investigation. It is time to take to heart the truth stated by Mr. Martin Dies of Texas, as recorded in the Congressional Record, itself rich in evidence of the unnecessary printing of speeches that were never made. This Congressman from Texas reminded his hearers that "Government is not created to support the people but is a creature supported by the people." The Government asks us to save and yet affords the spectacle of spilling the revenue with a lavish hand in every direction, from sending a couple of hundred ensigns from New York to San Francisco, where they remained in idleness varied by dissipation for three months before being sent back whence they started, to handing out billions of dollars for unproductive experimentation in aeroplanes. While our Government and our people are wasting money in every direction, millions are in want or are actually starving in Europe and elsewhere, and the hideous bogey of bolshevism gibbers at us from amid the morasses of defeat and disorder. It is the cost of high living, not the high cost of living, that is a menace to this representative democracy we are proud to call the United States of America.

DISCUSSION

The Yerington District

The Editor:

Sir—The abstract from Professional Paper 114, U. S. G. S., on the geology of the Yerington district, in Nevada, could have been read by no one with more interest and appreciation than it aroused in me. I spent several months in this district last year working up data to guide the prospecting and exploratory work of one of the larger companies operating there, and more than once expressed the wish that the Survey might give us a complete report on the district as a whole. I had hoped, if the opportunity arrived, to contribute something in this direction, and it is gratifying to find my observations and hypotheses supported in so large a measure by such an experienced observer as Adolph Knopf.

My investigations led me into a detailed mapping of geologic structure in the Ludwig, Casting Copper, Douglas Hill, and Western Nevada mines, combined with what microscopic research I could do at Ludwig. I made a distinction between fault-fissures, which Mr. Knopf emphasizes as controlling ore deposition, and fissures along which little, if any, movement had occurred, which latter, if trending more or less nearly parallel with the axis of the Singatse range, I held to be, in general, the localizing agents of primary ore deposition in the metamorphosed limestone. My maps aimed to picture the occurrence of ore with relation to these structures, as well as to the igneous rocks, to the pure marmorized limestones, to the less highly metamorphosed portions of strata, and to the more highly metamorphosed portions marked by strong development of garnet and diopside.

It always seemed to me that the term 'contact-metamorphic' was misleading in its application to the Yerington ores, for none of the orebodies to my knowledge borders on an intrusive or shows any such close structural relationship. Igneous exposures are rare near mineralized ground in the mines named above, although intrusive masses of quartz-monzonite lie but short distances from any of the mines. But many of these latter exposures are profoundly affected by the metamorphism and some consist almost wholly of garnet. I believe the primary ores were deposited along fissured zones during the final stages of an aqueo-igneous process. It seems to me that shrinkage of the pure limestones, on metamorphism to garnet and pyroxene, caused the fissures to form, mainly along lines paralleling the igneous core of the range. We find ores of the type most common to the district traversed longitudinally by such fissures, strongly developed in the garnet pyroxenite and dying out in the less altered limestone.

Of course, there has been movement on some of these older fissures, and some cross-fracturing has occurred, especially in the brittle, hence weaker, localities occupied by sulphide orebodies. These later fractures were of great importance in aiding subsequent enrichment by descending water, without which, I am sure, few ores of the district would be of smelting grade, say, 2½% and above. The garnet ores of the Western Nevada are an exception, having about 75% of their copper value in primary chalcopyrite as against 50% or less for ores from the Ludwig, Casting Copper, Douglas Hill, and McConnell mines; in fact, the Ludwig would never have been the mine it has been but for a large strike-fault traversing the mine; this so broke and crushed the country and the primary orebodies as to lay it open for active replacement by descending waters, and subjecting the sulphides to enrichment.

From the two geologic sections given in the abstract as well as from my own observations, I am inclined to regard the strong faulting and brecciation, so interesting to the miner, as decidedly later than the period of metamorphism and primary ore deposition. In the Casting Copper and Douglas Hill mines I have observed the network of euhedral yellow garnet veinlets in fractured fine-grained garnetite. This I believe to be incident to the fissuring that preceded the garnetization, but not to represent a breccia. The rock is fractured, but in place. I have some interesting thin sections showing this. Where yellow sulphides appear to form a filling around fragments of garnet ore the occurrence has been in an orebody much broken by minor slips of recent origin, also in the zone of sulphide enrichment, and with all possibility of the pyrite or chalcopyrite being a supergene mineral. Neither has recent exploration in the Casting Copper mine, along the boundary between the calcium silicate and pure lime carbonate areas, demonstrated a zone of brecciation, as some have inferred from the peculiar surface exposures above on the same "contact". I should also add that the primary ores, while probably favoring this transitional boundary, are garnet ores, even though they lie within a marmorized limestone. I wish I had space to describe the sort of outcrop that marks the mineralized fissures where exposed in the marmorized limestone.

If one is prospecting mines in this district, and others like it, careful analysis of structure is necessary; and I think too much emphasis cannot be given, as Mr. Knopf does, to the dependence of ore deposition on fissuring. My work was restricted to the business of outlining a scheme of exploration and the finding of ore; both these were accomplished in satisfactory degree, and if future developments prove as fortunate, a detailed account of the geology of these mines may be worthy of publication. The Yerington district has had drawbacks that cannot be laid to Mother Nature.

WALTER E. GABY.

Santa Rita, New Mexico, April 8.

Invention: What Is It?

The Editor:

Sir—Life in the mountains, at this time of the year, offers attractions and opportunities for observation and meditation that those who dwell in cities have but a faint conception of. The snow-fall has been heavy this winter; the huge drifts and the miles and miles of great pine-trees, each with a load of glistening snow on its branches, make an awe-inspiring sight, especially when one considers that the piling of the snow on the tops of the mountains is part of the system of the Great Master Hand, in providing food for those who toil and labor in the valleys below. "They (the waters) go up by the mountains: they go down by the valleys unto the place which thou hast founded for them;" and down in the valleys are great dams, one of which is over 350 ft. high, and vast irrigation systems, to impound the waters and distribute them over the former arid wastes, but which are now converted into the most fertile farming-lands.

The irrigation systems are the pride of man, and the engineers who conceived and constructed them are loaded with praise, and rightly so. But what, after all, is the feat of impounding the waters to that of lifting them from the seas, and piling them upon the tops of the mountains, and by a method, apparently so simple, that most of us pass it by as being merely Nature! Truly we can say to such, "Hast thou entered into the treasures of the snow?" and sought out Him "who bringeth forth the wind out of his treasury?" If not, there is an experience awaiting those who will but spend a winter in the glorious mountains, where storms seem to receive their birth, and the wind howls with fury as it sweeps through the pines. "Oh that man would praise the Lord for his goodness, and for his wonderful works to the children of men!"

Some years ago I spent the winter at one of the old mining camps away back in the mountains, which had seen its palmy days back in the 'seventies, and which has now to eke out an existence on the memories of its past glories. Timber is scarce in such a camp, as the miners in the old days had not studied the principles applying to the conservation of natural resources; and the storms sweep unimpeded over the bare mountains, piling the snow in huge drifts that 'cone' over and provide fine opportunity for the boys to do 'stunts' on their skis.

Many of the old-timers are still there, each living in some venerable shack, left intact from the ruins around. Every evening they meet, with common consent (including that of the proprietor), around the huge stove in the lobby of the one hotel, and recount their experiences of bygone days. They tell of ore of wonderful richness left at the bottom of the shafts now filled with water; many an unwary visitor has been lured by these stories to raise money for re-opening an old prospect, only to find that the old-time miners knew the good ore about as well as we do now, and that what they left is not likely to make many of us rich. I have heard it hinted that these evening meetings around the hotel stove were to save fuel in the individual stoves at home—this may be so, but I would impute a different motive as the chief incentive, as I have often listened to the learned discussions into which these old solons invariably lapsed.

One evening, when the wind was "blowing great guns" and the snow drifting in blinding waves, I put forward the following question for discussion: "What is invention?" The first answer was, "Why, you get an idea, and make application to the Patent Office and get a patent." This, of course, is just a patent, and there may, or may not be, 'invention'. Another answer was, "You have an idea, and you work and work at it till it works, and then you get a patent." This seemed to me to fill the bill better, especially as Mr. Edison, who ought to be an authority on this subject, says that 90% of invention is hard work. I then asked where the idea comes from, and the general opinion was, "why, you just get it." The discussion about the "idea" continued till late in the evening, but we did not make much headway. I have often thought of the definition of 'invention' as being like that of the Irishman of salt—"it is the stuff that makes potatoes taste bad when you don't put it in"—as, in so many cases, an invention is that which makes men rich who didn't make it.

To illustrate the idea factor of invention, I will give an experience I had many years ago. I was in charge of a mine, and in order to eke out the handsome salary I was receiving, I went into a venture to re-treat a large deposit of tailing, and induced several friends to go in with me. A plant was erected, which cost considerably more than we had figured it would—not an unusual case, I believe; and after we got started all sorts of unlooked for difficulties arose, the chief of these being the absolute failure of some huge stirring devices put in at my suggestion. The things simply wouldn't work. Our limited capital was vanishing, because, if there is anything that eats up money quickly, it is a plant that does not run properly—I truly think we could add this to the four things which Auger, the son of Jakeh, in the Book of Proverbs, sets forth as being never satisfied. In desperation I cabled my company tendering my resignation, unless they could allow me two days each week to visit this plant. The permission was granted, and all my thought and endeavor was directed to the saving of the money my friends and I had risked in the undertaking. I pointed out to my partners that if the stirring device could not be made to work, we were done.

On one occasion I had been all day at the plant, and left late in the evening, with a long ride over the mountains in the pouring rain to reach home. I arrived at 2 a.m., drenched and chilled through, crept into bed, and after a while fell into a sort of slumber. Those who have made a study of the sub-conscious mind say that when a person goes to sleep, he commences to dream, and this continues all through his sleep, but the only dreams or portions of them that are impressed on the conscious mind are those that occur just before waking—the connection of the absent with the present, as it were. When I awoke it was daylight. In my dreams I had been talking to someone, and these words were left ringing in my ears, "Why not put a chimney in it?" I puzzled over the words all day, as I had an intuitive knowledge that they contained the key to the solution of my difficulty, and my wife and some visitors remarked how strange and preoccupied I was.

As soon as the assayer had finished his work for the day, I took possession of the laboratory and started experimenting, and I soon began to get on the right track. At about 10 o'clock, my wife came down, determined to find out what was the matter with me, and in answer to her enquiry as to what I was doing, I jokingly told her that I was on the eve of a great invention. In order to get compressed air for my experiments, I pumped the tank used for the gasoline full, and attached a rubber tube to the small pet-cock at the top of the tank. I was so eager to watch the operation of the apparatus I had constructed that I lit a match to get more light, and lo! the whole thing blew up—I had forgotten that I was using air mixed with gasoline vapor. I had to start all over again, but at 2 a.m. I had the thing perfected—it worked—and strange to say, the principles of it have never been altered.

In a few weeks we were over our stirring or agitation difficulties, but alas! our capital was exhausted, and anyone who understands mining will realize how hopeless the situation is without money. I went to London to try to raise capital, and incidentally, to try to get someone interested in my invention, as I had no money left to take out patents. I prepared drawings, thinking that engineers would jump at so simple a device, but, nothing of the sort, and I began to get some experience of the 'wet blanket'. Fortunately my company had faith in me, and they put up the money for the patents for an interest in the invention. One well-known engineer, before whom I placed it, said in a condescending way, "Of course, it might work in a laboratory, but we could never use such a device for practical work." It was some satisfaction, a few years later, to have one of the mines with which this man was connected put in a large number of my stirring-machines.

In the meantime the plant was shut down and was the joke of the district, and often when I had to pass by it, while riding with my wife to a neighboring town, I would tell her to look the other way, so as not to see it, and we christened it "the nightmare". Eventually the whole concern was advantageously sold to a company organized to operate it, and for many years, from 400 to 500 tons per day were treated, the war conditions finally bringing about a cessation of operations. The invention brought in large royalties, some of which actually found their way to the inventor.

As the years roll by, I often ponder over these things; I am a great reader of the Bible, as I consider this the book of books, and I recall the time when young Daniel and his three friends were in deadly peril because no one could give the meaning of the dream which the great king had had, but had completely forgotten. Yet the secret was revealed to Daniel in a night vision, and in his prayer of thanks and praise, he blessed his God "who revealeth the deep and secret things."

There is one thing I have been impressed with in my 30 years of mining life, and it is that perseverance in honest endeavor will bring some good result, though often quite different to that expected or sought for. This might be termed the 'work' factor or aspect of invention. "Necessity is the mother of invention," which perhaps expresses the same thought as "Man's extremity is God's opportunity," and the God-given idea, followed by man's persevering effort, will "save him out of all his troubles."

Quartzburg, Idaho, April 10. F. C. Brown.

The Status of Gold

The Editor:

Sir—Will you permit me to make a short contribution to a rather lengthy discussion on this subject by relating some things I have seen and heard rather than venturing an opinion, for I have learned not to value even my own opinions as highly as I once did.

Axiom: You can make two bites of a cherry, but you cannot make two cherries by biting one. Corollary: A bitten cherry is worth no more than a whole one. Scholium: Each man will for himself interpret this as an axiom, a theorem to be disproved or a foolish remark and his judgment will be final for there is no court of appeal.

Now, my brothers, if you will listen a moment I will tell you how I was in a few things as wise as the mountain lions and the foxes and the coneys that live among the rocks. Once upon a time a man who was then young arose in a Chicago convention and made mention of a crown of gold. His speech was so charged with something akin to magnetism that there went out many orators, likened to a swarm of grasshoppers, with speeches which they had learned by heart from a book called Coins' Financial School, saying: "We will take 16 ounces of silver now of the value of ten pieces of gold and we will split the silver into twenty pieces and when these pieces are stamped in a press they will be worth twenty pieces of gold." They said to the farmer that would make his dollar wheat worth two dollars, but the farmer replied, "I will in truth need two, for your new dollars look to me like fifty cents." Then they said, "The product of your toil is low because there is a money famine, but we have a plan whereby such famines will cease forever." But the farmer replied, "All you can do is to make the money into more pieces, but I work early and late and have no time to count such money.'' Then they showed the farmer how he could pay his debts at half-price, but, with some impatience, he said, ''Go to; I will pay according to my promise.'' Some said it was hayseed in his hair but others said it was brains in his head and uprightness in his heart that caused the farmer to say these things, and I mention this to show how in important matters men are not always agreed. Then the orators told their story to the men who dig for silver and some fell for it, but others were not greatly impressed, for they said they did not want silver to use but only to sell to their Uncle Samuel. And so it fell out that after the November election the orators were heard no more.

But now prices are high, for in time of war men clamor loudly for all kinds of stuff and will brook no delay, valuing money but lightly, being content if it bring them only a little of what they most need and that quickly. One day while I was musing on these things a strange appearing man came before me dressed in a flowing robe on which were embroidered in gold various mathematical signs and formulas. He told me that the same cure proposed in former times for low prices would heal all the disorders of the present time, including even the low price of British consols, and the cure was simply to split our twenty-dollar gold-pieces in two parts, thus doubling the value of the metal. He said such marvelous cures were not unusual, for in times past was there not a liquor that would keep out the heat as well as the cold besides curing ills of the mind as well as of the body? But I told him I feared the people who believe in axioms would raise objection and say that even Consols will recover when the clamor for stuff is somewhat abated and men turn their attention to these securities and are content with the modest return therefrom, but if the increase on Consols is paid in pounds of light weight, as he proposed, these securities might go still lower; that many men have no faith in certain kinds of new schemes, and say that touching what they call basic principles there is no new thing under the sun; that even our ancient friend Euclid made no invention but taught us only things that had been from the beginning of time. For these men have been made tired by hearing much speaking and are become apt in laying snares for reformers. In this I saw that the man agreed with me, for he said, ''I have a plan for overcoming the enemy by noiseless speech and if we cannot refrain from writing let us write upon the air and save both paper and ink. Let us discard the alphabet of 26 letters that represent so much noise and confusion and turn to the Arabic or decimal system whereby we can operate the rule of three, the slide-rule, or other like devices that emit no sound whatever. We remember that all the pictures of Coin show him making figures upon a blackboard whereby he started a wonderful crusade, but his followers talked, and in that they made the mistake of their lives. Let us then take to figures, which are both accurate and convincing, but eschew logic, which is a pitfall for the unwary and something that all do not understand. Some of us might express our burning thoughts upon the abacus, but I use the figures you see on my garment. However, a frock-coat would be sufficient for some men, for what logic could be more unanswerable than a wave of the coat-tail, writing as it were upon the air in dignified silence? They should also carry a piece of chalk, as Coin did. Do you say blackboards would be inconvenient? Ah! but they shall make figures; figures, yes, figures on their coat-tails and thus hurl our theorems into the very teeth of the foe.

I might have laughed at the strange proposal of the man had not my vanity been tickled by his agreeing with me in some things, and, as I fell under the spell of his eloquence, I looked out on the plain and saw his plan working, or rather playing, for the people had ceased to work and were joyfully splitting the dollars they already had instead of laboriously searching for more gold as I had been doing that day. I saw the earth transformed into a paradise while zephyrs from flowery fields wafted perfume to my nostrils and the rippling laughter of the four rivers made music in my ears. I saw one man in admirable pantomime demonstrate by mathematics that if a dollar were split once every minute there would still be metal left in it for a gold standard.

Then my head bumped against a rock and I arose quickly, but the man who had talked with me was gone. The only reminder of the perfume wafted from Elysian fields was the fragrance of the burning cedar with which I had kindled a fire a short time before to dry my clothes as I sat down in the shelter of a rock to refresh my body by chewing a piece of green bark from a near-by shrub, for I had nothing to eat. The crags above me frowned inhospitably, the keen wind made me shiver, my camp was miles away, and there were no winged horses standing ready to carry me thence. I did not even think of conjuring horses or chariots to my assistance, as one might have done after seeing such wonderful things, but started out over a broad expanse of rock with hardly a seam, for I was at the foundation of things, amid large-scale realities, on the very floor of the world, with no kindly soil to cushion my footfall and at every step my aching feet came in contact with a perfectly sound axiom. I did not even speculate on a plan for splitting the miles to make the way shorter, for when a man is traveling alone and night is coming on and a raindrop now and then falls in his face all his faculties become alert after the manner of the leopard when she hides her kittens from the fury of the hurricane while it is yet in the distance. Even fatigue will be forgotten and one will settle into a stride that will put the miles behind as rapidly as when setting out in the morning.

Now, whether it was the logic of my head or of my heels that should have the greater credit for causing me to come in out of the rain I care not, for I hold that a man is at his best when some emergency awakens all his faculties to equal action, for then he will clearly see the Things that Are. So it happened that in a few things I was as wise as the mountain lions and the foxes and the coneys that live among the rocks.

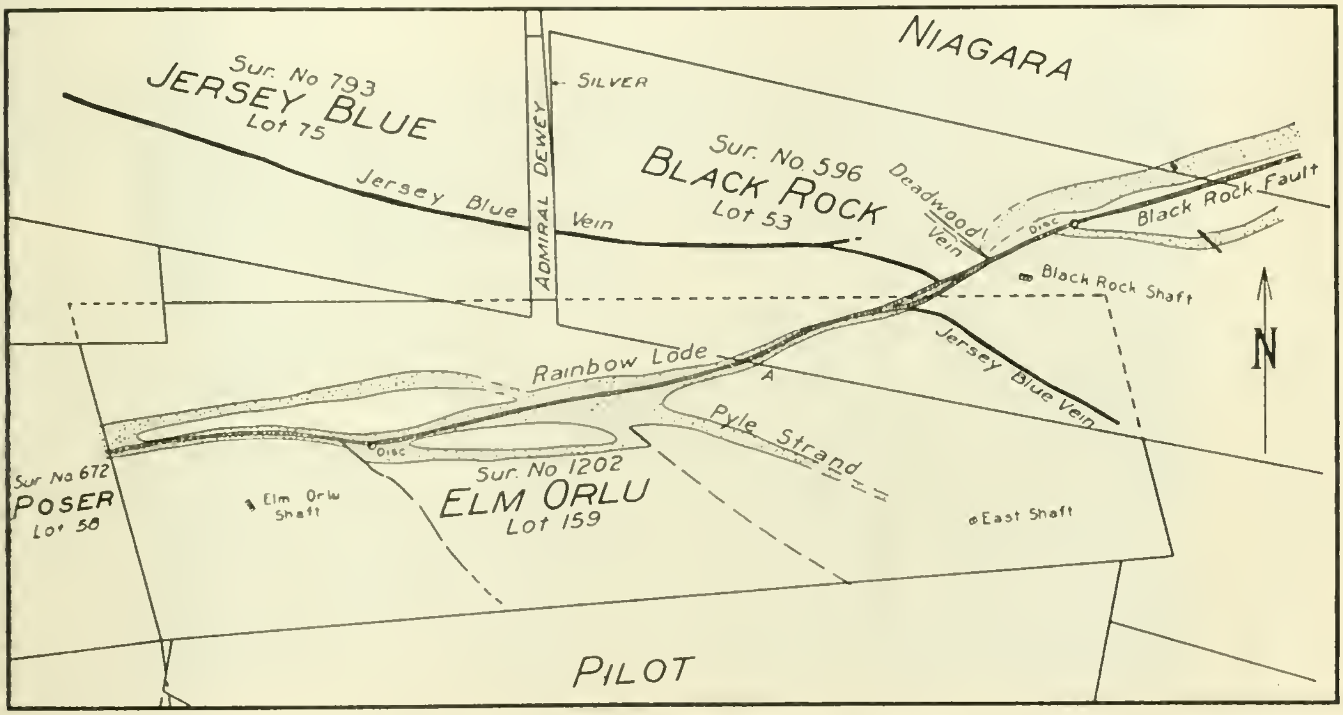
JOHN RANDALL.

Mogollon, New Mexico, April 21.

The Elm Orlu Case

By ROBERT M. SEARLS

Whenever, after a judicial silence covering a period of several months, the mining world begins hopefully to conclude that probably the last word has been said on extra-lateral questions, a new case is sure to bob up and demand scrutiny. The latest contribution to the bewildering maze of decisions is the ruling of the Supreme Court of the United States in the case of Butte & Superior Copper Co. v. Clark-Montana Realty Co., more familiarly known as the Elm Orlu case. The opinion, written by Justice McKenna, decides an appeal taken by the Butte & Superior Copper Co. to review a decree of the Circuit Court of Appeals, Ninth Circuit, affirming a decree of the District Court for Montana in favor of the Clark-Montana company.



MAP OF THE GROUND IN DISPUTE AT BUTTE, MONTANA

The facts as found by the trial court, and upon which the opinion is based, will be made clearer by reference to the accompanying diagram, which is presented through the courtesy of John P. Gray, of Coeur d'Alene, Idaho, counsel for the appellees.

The Clark-Montana company owned the Elm Orlu claim and had leased it to the Elm Orlu Mining Co., which was also one of the appellees. The Butte & Superior Co., appellants, were owners of the Black Rock, Admiral Dewey, and Jersey Blue claims. The Elm Orlu was the prior location, but the Black Rock, Admiral Dewey, and Jersey Blue patents were granted first. Owing to the failure of the Elm Orlu owners to adverse, the Black Rock patent included the surface areas in conflict; and the same was true of the Admiral Dewey and Jersey Blue patents.

The main vein involved in the dispute was the Rainbow lode, which enters the Elm Orlu claim through its westerly end-line and passes out of the claim through the northerly side-line, dipping steeply to the north. Near the centre of the claim the Rainbow lode splits into two branches, the southerly one of which was termed the Pyle strand and extended easterly in the Elm Orlu claim for a disputed distance. The Pyle strand was considered as part of the main vein and not as a secondary vein. The Jersey Blue vein crosses the west end-line of the Black Rock claim and coursing easterly through the claim for a disputed distance crosses the Rainbow lode on both dip and strike. The Pyle strand, dipping north at a flatter angle than the main Rainbow lode and changing its strike almost due east as it dips, unites with the Rainbow at the 1100-ft. level beneath the Black Rock claim. The orebodies in dispute lie in the Rainbow lode under both claims, and vertically beneath the territory traversed by the common side-line

Inasmuch as the owners of the Elm Orlu lost their right to that portion of the Rainbow apex lying northeasterly of the common side-line between the Elm Orlu and the Black Rock, owing to their failure to adverse the patent, their extra-lateral rights based on the main

Rainbow apex would be terminated by a plane passing through the point A parallel with the Elm Orlu west end-line. However, they could show an apex on the Pyle strand entirely within the Elm Orlu prior location; and this, as has been stated, dips to a junction with the main Rainbow lode at the 1100-ft. level. This Pyle apex did not outcrop at the surface and its easterly course beyond the terminus shown on the map was so far a matter of speculation that the trial court refused to make any finding beyond that point, and expressly left the case open to further determination when actual work should have developed its course and extent. Enough was shown, however, to justify the conclusion that the owners of the Pyle vein were entitled to the orebodies lying within its demonstrated extension. This, it will be seen by reference to the plat, would include the orebodies in dispute beneath the common side-line, because a plane passing through the terminus of the Pyle strand shown on the map parallel with the Elm Orlu west end-line would intersect the main Rainbow vein east of those orebodies. Such was evidently the conclusion of the Court in quieting the title to them in the Elm Orlu owners.

Both the Circuit Court of Appeals and the Supreme Court confirmed these findings on appeal. The Supreme Court also discusses several points of law that were raised. It appeared that the locators of the Elm Orlu did not comply fully with the local requirements of the laws of Montana in making their location, and the Black Rock owners therefore asserted that no claim could be based on the seniority of location. Several decisions of the Montana courts were cited to that end. In reply the Elm Orlu owners contended, first, that the Federal courts were not bound by the Montana rule; second, that the Elm Orlu people were at all times in possession of and working their claim, of which fact the Black Rock owners had due knowledge; third, that the defects in location were cured by patent. The Supreme Court upheld the latter two contentions of the appellees, observing that the first one also "had impressive strength and was conceded to have in Yosemite Gold Mining & Milling Co. v. Emerson," and that the Montana legislature had largely nullified the State court rulings to the contrary through curative statutes. The Supreme Court's reasoning seems to be that local rules designed to give constructive notice to other locators need not be strictly observed, providing the acts of the locator are such as to put such others on actual notice of his rights.

The Court then goes on to say that if the Elm Orlu location was senior to the Black Rock when patent was issued to the Elm Orlu, its senior rights were confirmed even though the date of the patent itself might be subsequent to that of the Black Rock. The rule in Lawson v. United States Mining Co. that in the absence from the patent record of an adverse suit, nothing is determined by the patent except surface conflicts is re-affirmed. The Black Rock owners by their prior patent thus gained title to all of the surface of the Elm Orlu lying northeasterly of the south Black Rock side-line, and the latter line became then the common side-line to both claims. But the Elm Orlu location being senior to the Black Rock, the owners of the former could still assert extra-lateral rights upon the Pyle strand, and, as the latter united with the Rainbow on the dip, could quiet title to the orebodies at and below the point of union.

There was some discussion also as to the effect of a quit-claim deed given by the Elm Orlu owners to the appellants, covering rights based on the Black Rock location which the Supreme Court held irrelevant, and finally the Court approved the action of the District Court in reserving for later determination the extent of the rights of the appellees in an easterly direction on the Pyle vein.

The case, as a whole, does not decide any particularly novel questions of law, although it embodies an interesting play of facts. If a corollary is to be derived from the decision, I might phrase it by saying "There is nothing like having several apexes to your vein." The opinion is of real value, however, in confirming the rule that a locator may not be foreclosed of his extra-lateral rights by failure to adverse the patent application of an adjacent claim, where he retains the apex and the existence of a sub-surface conflict is not known.

The perfection and production on quantity basis of helium, the non-inflammable gas, by American chemists is one of the most amazing scientific achievements of the War. If Germany could have filled the gas-chambers of her huge zeppelins with it instead of hydrogen gas there would have been a different story written of their accomplishments in the War. But helium was one of the rare gases. Its cost ranged from $1500 to $6000 per cubic foot. When we entered the War the Allies told us that there was a crying need for a balloon-gas that would not burn. They suggested that our chemists pay some attention to helium. That the attention given was most thorough and adequate is shown by the fact that the cost of manufacture was brought down from $1500 to 10 cents per cubic foot, and even this figure may be lowered.

The group of gold mines in the Kolar field of India the Balaghat, Champion Reef, Mysore, Mundydroog, and Ooregum—having a total monthly output of $820,000, are all under the one general management, and combine for general purposes. For instance, the Cauvery River power-plant, 90 miles distant, the steam power-plant at the mines, the brickmaking works utilizing mill-slime, and the medical establishment, are all jointly operated.

Experience has proved that wear on rope increases with speed; therefore, true economy results from increasing the load within the safety limit and diminishing the speed.

Waste heat from four reverberatory furnaces at the Calumet & Arizona works at Douglas produces steam that generates 1000 kw. of electric power for the mine at Bisbee.

The Divide District

By FRANK L. SIZER

Introduction. The impetus given to prospecting by the recent favorable development of the Tonopah Divide mine can hardly fail to bring some good results to that part of Nevada which is tributary to Tonopah and Goldfield. The fact that the Gold Mountain mining district has been so late in 'coming into its own' is not at all strange, since the more attractive surface showings of the two big mining centres, above mentioned, more quickly claimed the attention of the miners. To a very few of the faithful ones, who showed their faith by 'good works' (and in one instance spent $25,000 in development) is due the present success of the Divide mine and the consequent 'boom' in surrounding properties, now well under way.

THE TONOPAH DIVIDE MINE

The situation of Gold mountain, only five miles from Tonopah and the ready access to the new district afforded by hundreds of automobiles, make it easy to visit. The accommodations, though crowded, will undoubtedly be enlarged, and visitors are fortunate in having the established settlement of Tonopah as a base to work from.

Tonopah is the nearest railroad station, but a spur from the main line between Tonopah and Goldfield is already under discussion and will be built if the present indicated importance of the new district is maintained.

Geological. The important geologic features are the pronounced tissuring of the area now under discussion, in which the Divide vein occupies a central position, and the volcanic uplift, which undoubtedly is responsible for this tissuring. The Divide mine is on the east flank of Gold mountain, which in this description is called the central intrusive mass. The High Divide and adjacent ground occupy the larger part of a mountain one mile east of the Divide mine; the Hasbrouck ridge is one and a half miles west of Divide.

The main lines of fracture have a north-west strike, the general parallelism of these fractures being particularly noticeable and significant. The fact that an important ore-shoot has been opened in the ground of the Tonopah Divide company naturally directs attention to this fissure system; but there is no good argument to be advanced against the probable discovery of ore in quantity on some portion of other veins, many of which are so prominently exposed in the immediate vicinity of Gold mountain.

The engineer who writes of this district six months from now will have the advantage of me, by reason of exposures made by the shafts and cross-cuts now in progress. My present diagnosis is offered as a tentative analysis of structural conditions, after ten days observation of all that can be seen on surface, as well as under-

Tonopah is Over the Ridge

Tonopah Divide Mine

GOLD

ground, in the district, and some omissions will doubtless be supplied after a subsequent visit.

The subsidiary fissuring, which has varying strikes from east-west to northeast-southwest has no known importance, although this minor fissuring was the basis of many of the older locations, upon which the prospecting of narrow widths of gold-bearing quartz has been carried on, in a somewhat desultory fashion, for the past sixteen years. The favorable development following the discovery, about eighteen months ago, at a depth of 165 ft., of the wide vein of silver-gold ore now constituting the Divide ore-zone, has completely reversed the previously expressed opinion of some of the best informed engineers, that the mineralization found in the Divide vein was erratic and undependable, lacking in silicification and not likely to persist to any great depth. This feature having been answered affirmatively, to a depth of 470 ft., it now remains for speculation as to prospects when the primary ore is reached.

Apparently some importance attaches to the ratio existing between silver and gold in the average ore of the Divide vein, which is in the proportion of 100 ounces of silver to one of gold; or, in other words, five times as much value in silver as in gold. This happens to be the ratio noted in a majority of the Tonopah ores, and agreement on this matter influences opinion as to the probable persistence of the ore at Divide.

As to the formation in which the most favorable conditions of deposition will obtain, it is a little early to make predictions; but it is generally conceded that the rhyolite cap, 80 to 400 ft. thick, must be penetrated before the ore-bearing rock, the Divide breccia, is reached. The mineralization, in dike or vein, within the limits of the Divide breccia is continuously favorable, if we are to judge by the result of the limited development already open to inspection. There is evidence, in places, that the Divide breccia is exposed on surface, by the erosion of the rhyolite cap; but so far as known to me, petrographic work on the rocks of the district has been limited and some of the opinions expressed are colored by the desire of the individual to see Divide breccia as soon as the first few shovelfuls of rock have been removed from the ground.

It is apparent that oxidation and subsequent leaching in the fissured zone has reduced the metal content near the surface and probably localized the richer ore in chimneys, bunches, or short shoots, so that speculation as to the effect of re-deposition, and the merging of oxidized into sulphide ore, will remain an open question, and an important one, until a considerably greater depth is attained, possibly 300 to 500 ft. deeper than the present bottom level of the Divide mine.

In Professional Paper No. 104, of the U. S. Geological Survey, Messrs. Bastin and Laney state: "The solutions that deposited the great bulk of the minerals of the Tonopah ores were exudations from cooling, buried bodies of igneous rock or magma. * * * In a region where there has been recurrent volcanic activity, it is possible, if not probable, that similar mineralization might take place at more than one period." These differing periods of mineralization will probably be identified in the Divide district, as work proceeds.

The important practical feature seems to be that the veins, to a considerable depth, are subject to the oxidizing influences that permitted a deposition of the gold near the surface in the minor fractures and a more liberal and important concentration of silver-gold ore in the major fissures that traverse at least one mile of the district from north-west to south-east. That some of the parallel veins may yield orebodies is highly probable, but their possible value, as compared with the Divide mine, is open to a wide range of guessing. The occurrence of gold in the ore of these veins at or near the surface is taken by some operators as a favorable sign, whereas others take pride in saying that their dikes, on surface, are just like the Divide dike, in that they show no assay-value whatever. Undoubtedly, the gold-value on the surface, in some of the fissure-fillings, is due to the removal of other constituents of the vein-matter, and yet the gold found in the larger veins has been almost negligible, with silver showing only at depths of 100 ft. or more.

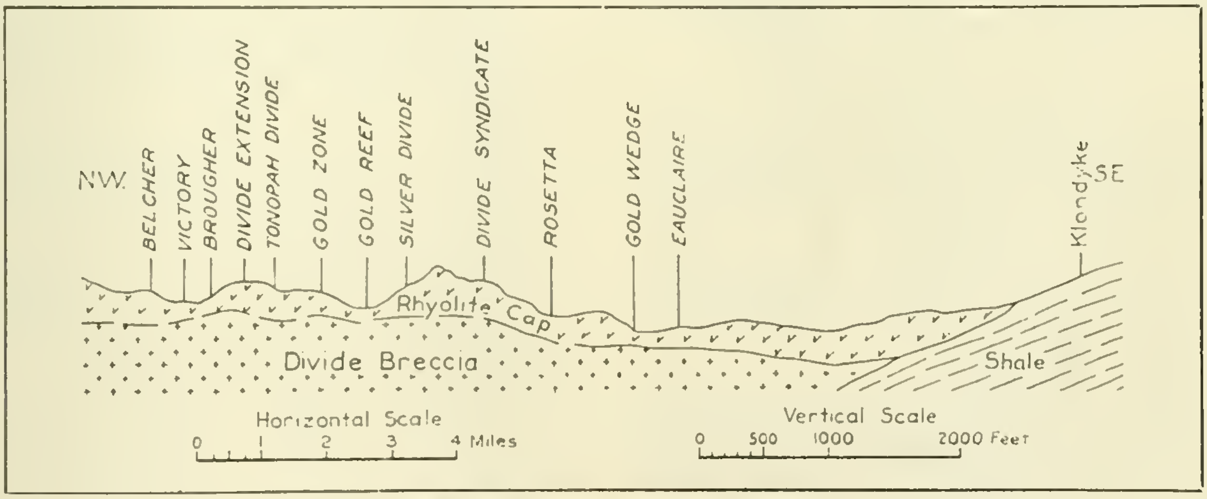
MOUNTAIN

Toward Goldfield

FINANCIAL. The companies that have been financed for exploratory work are all planning to sink shafts to a depth of 500 ft. or more, and in many instances they will not do any driving or cross-cutting until this depth is reached. Development now in progress will doubtless alter previously announced plans, by reason of changes of opinion which are quite likely to occur in a district as new as this. Any opinion as to depth at which the breccia will be reached is subject to early revision as the work progresses.

The Tonopah Divide mine has four levels 100 ft. apart, each exposing the orebody, and a fifth level, at a depth of 570 ft., from which a cross-cut to the vein is now being driven. The greatest length of ore so far developed on any level is 480 ft., and the width is from 30 to 50 ft. On the third level, a cross-cut into the hanging shows from 10 to 16 oz. silver per ton for a distance of 50 ft. beyond the assumed position of the hanging wall. A gouge separates the ore from the foot-wall rhyolite, but the hanging wall is not so clearly defined. On this gouge, and along similar seams interior to the mass, hornsilver can frequently be seen, accounting for some of the very high assays that have been given to the public. Estimates of visible ore in the Divide mine have varied from $5,000,000 to $9,000,000 gross, the latter figure, in my opinion, being justified only on the assumption that the fifth level will soon prove the vein no less in size and value than on the fourth level, the best showing in the mine.

The general geology, along the strike of the Divide vein, is depicted on the accompanying sketch, which is a compilation of the ideas of those best acquainted with the district and is here offered in a tentative way until further development work makes certain some of the doubtful points. The thickness of the rhyolite cap and the depth at which the Divide breccia merges into some other formation are points that will influence the speed at which development will proceed and the ultimate success or failure of some of the operations now under way.



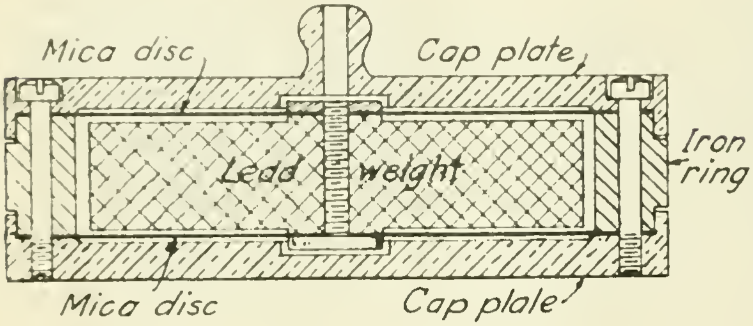
LONGITUDINAL SECTION ALONG THE STRIKE OF THE DIVIDE VEIN

The near neighbors of the Divide mine are those for whom expectations of early favorable results are reasonably assured; but this does not bar the strong probability of ore being found on some or all of the parallel fissures: it is this that constitutes the greatest hope of the district becoming an important silver-producing centre.

An Underground Trouble Detector

The geophone, a listening instrument invented by the French during the War to detect enemy sapping and underground mining operations, also for the position of artillery, is now being used by the U. S. Bureau of Mines as a possible aid in locating miners who have been entombed after a disaster. The instrument was developed by American engineers, and is now used by the Bureau according to plans drawn by these engineers. Alan Leighton, assistant chemist for the Bureau, who now has charge of these investigations, has given the following statement of general information regarding the geophone.

The instrument, though small, is essentially a seismograph, since it works on the same principle as the ponderous apparatus with which earthquake-tremors are recorded. It consists of an iron ring 3½ in. diameter, within the centre of which is suspended a lead disc fastened by a single bolt through two mica discs, one of which covers the top and the other the bottom of the ring. Then there are two brass cap-pieces, the top one having an opening in its centre to which is fastened a rubber tube, leading to a stethoscopic ear-piece. These cap-pieces are fastened with bolts to the iron ring, and also serve to hold the mica discs in place.



SECTION OF A GEOPHONE

The apparatus is really nothing but a lead weight suspended between two mica discs across a small air-tight box. If the instrument is placed on the ground, and anyone is pounding or digging in the vicinity, energy is transmitted as wave motion to the earth, and the earth-waves shake the geophone case. The lead weight, on account of its mass and because it is suspended between the mica, remains comparatively motionless. There then is produced a relative motion between the instrument case and the lead weight. The result is that a compression and refraction of the air in the instrument takes place. Since the rubber tube leading to the stethoscopic ear-piece is connected with this space in the geophone, this rarefication and compression is carried to the ear-drums. Usually two instruments are used, one for each ear.

When the two instruments are used, it has been found that the sound is apparently louder from the instrument nearer its source. It is evident that by moving the instruments properly, a point can be found when the sound will be of the same apparent intensity in both ears. The direction of the sound is then on a perpendicular to the line connecting the centres of the two instruments, either in front of or behind the observer. Further observation will show which side. Direction is accurately determined in this way. The sound is not actually louder in one ear than in the other, but the ear is capable of distinguishing the difference in time at which the sound arrives in the two instruments. Since this is the case, persons who are slightly deaf in one ear are said to still be able to determine direction with the instruments.

Trials showed that sounds were transmitted only about half as far in clay as in shale strata, and about a quarter as far in clay as in coal. Pounding with a pick on bituminous coal can be detected for a distance of 900 ft., and the direction determined; and pounding with a sledge can be heard as far as 1100 ft. The explosion of a one-ounce charge of dynamite was detected a distance of over 2000 ft. through shale. One interesting feature of the instruments is that the sound as transmitted to the ear is characteristic of the instrument producing the sound. To illustrate: 12 mining and carpentering operations were carried out on the coal rib. An engineer of the Bureau who had never used the geophones, and who did not know what tools were to be operated, was able to recognize and name nine of the instruments at a distance of several hundred feet through the strata. The other three sounds were accurately described, but the machines were not identified. Wind greatly interferes with the successful operation of the instruments.

In metal mines, expensive surveys have sometimes to be made in order that approaching tunnel headings may be brought accurately together. Since direction can be determined so well with the geophones, it is thought that they can be used to guide such work. It would simply be necessary to go into each heading and locate the direction from which pounding in the other heading was coming.

Observations were made recently of a mine fire burning from 20 to 40 ft. below the surface. A low rumbling noise could be heard as if air were being drawn-in along crevices, and occasionally sounds could be heard from the snapping and falling of pieces of coal or rock. As well as can be determined, the fire-area was accurately determined, but owing to the fact that the fire cannot be approached from the inside the data cannot be checked absolutely. It is interesting to note that similar sounds could be heard from only one point on the inside of the mine, and that point was the one nearest the area as detected on the surface.

LEAD LINING in sulphuric-acid leaching-vats, lead piping, and lead-lined pumps should be inspected every time opportunity offers.

ABSORPTION of sulphurous-acid gas in the reduction towers of the New Cornelia plant in Arizona was 90.5% last year.

The German Metal Octopus—III

ISSUED BY THE ALIEN PROPERTY CUSTODIAN

(b) L. Vogelstein & Co. (Inc.) Aron Hirsch & Sohn was ten years behind the Metallgesellschaft in establishing a branch in the United States. In 1897, Ludwig Vogelstein started an agency for Aron Hirsch & Sohn in New York. Soon thereafter Vogelstein formed the firm of L. Vogelstein & Co. and associated with himself one Ernest G. Hothorn. In this firm Aron Hirsch & Sohn had a direct interest. The business was conducted as a co-partnership until the end of 1916, when the present corporation, L. Vogelstein & Co. (Inc.), was formed. During these 19 years the Vogelstein business was conducted purely as an agency of Aaron Hirsch & Sohn. There were agreements between Vogelstein and the Hirsch concern for the division of profits upon the American business and upon some of the European business. The business of Vogelstein & Co. was purely that of trading in metals, both for export and in the domestic market, and they were very active in importing copper ores into the United States. They contracted for the entire output of the mines, principally copper; and they were practically the only metal concern in the United States that imported ores. These importations were mainly from South America, where they contracted for the output of several mines. They had an interest in a copper refinery at Chrome, New Jersey, and the imported copper was refined there. They also had contracts with this refinery and others, whereby they were appointed the exclusive selling agents of the product of those refineries, or they contracted to purchase on a sliding-scale basis for the entire product of mining, smelting, and refining companies.

BEER, SONDHEIMER & CO., AND CONNECTIONS

In July 1901, Vogelstein entered into an agreement with the late Capt. J. D. De Lamar for the erection of an electrolytic copper refinery at Chrome, with a capacity of 3,000,000 lb. per month. De Lamar was to contribute 75% and Vogelstein 25% of the required capital. Vogelstein agreed to finance the copper business of the refinery in return for the sole selling agency for a period of years, for which financing he was to receive 1% commission. The plant commenced operation in 1902 under the name of De Lamar's Copper Refining Co. Since that time the capacity of this refining plant has been greatly increased and it is now capable of turning out 21,000,000 lb. per month. A smelter has also been added which has a capacity of 200,000 tons of ore per annum.

In 1905 Vogelstein bought De Lamar's entire interest in the refining company and sold a part thereof to the United States Mining Co., the predecessor of the present

United States Smelting, Refining & Mining Co. The name of the refinery has been changed and is now known as the United States Smelting & Refining Co. The capitalization of the refinery is $1,550,000 preferred and $1,550,000 common. Of both issues United States Smelting, Refining & Mining Co. own two-thirds and Vogelstein & Co. one-third. Vogelstein took a contract for a period of 10 years commencing January 1, 1906, for the exclusive selling agency of the refinery and for the financing of its operations. In order to facilitate these operations the International Metals Selling Co. was formed with an authorized capital of $250,000. Vogelstein & Co. and United States Mining Co. each taking half of the stock of the Metals Selling Co. The U. S. Mining Co. subsequently sold its interest in the International Metals Selling Co. to Vogelstein & Co., who now own all of it.

In 1916 the capital of the International Metals Selling Co. was increased to $500,000, Vogelstein & Co. paying into the treasury $250,000 cash. Vogelstein & Co. has used the International Metals Selling Co. as a buying and selling agency in South America, principally in Chile and Peru.

For ten years prior to October 1915, Vogelstein had the sole selling agency of the American Zinc, Lead & Smelting Co., and he financed its operations. When this agency terminated, a zinc-smelting plant was built in Arkansas and the Arkansas Zinc & Smelting Corporation was formed to operate it with a capital of $200,000 preferred and $400,000 common. L. Vogelstein & Co. took a five-year agreement with the corporation to finance its operations and act as its selling agent.

The following is a list of contracts for the purchase of the output of various mines which Vogelstein & Co. had during the years 1915, 1916, 1917, and 1918:

	Estimated output, tons
South American Syndicate, Tucacas, Venezuela copper ore	14,400
Sociedad Minera Backus y Johnston del Peru, Lima, Peru, copper bullion	12,000
Gatico Mining Co., Valparaiso, Chile, copper bullion	4,200
Chimborazo Mining Co., Lima, Peru, copper ore	3,600
E. A Orbegosa Lima, Peru, silver and gold ore	900
Bunker Hill Smelter, San Francisco, Cal., pig-lead	40,800
Arkansas Zinc & Smelting Corporation, Van Buren, zinc oré	24,000
Arkansas Zinc & Smelting Corporation, Van Buren, zinc metal	12,000
Butte & Superior Mining Co., New York, zinc ore	3,000

In addition, Vogelstein & Co. under contract with the United States Metals Refining Co., purchase about two-thirds of the entire production of the United States Metals Refining Co., amounting to about 96,000 tons refined copper per annum.

They had contracts whereby they were appointed exclusive selling agents for the following smelters and refineries: Arkansas Zinc & Smelting Corporation, Bunker Hill Smelter, and in part United States Metals Refining Company.

The business of Vogelstein & Co. developed very rapidly. The following tables show the annual turnover of the various metals for the past five years:

	Turnover Quantity Lb	Value
Copper		
1914	118,012,131	$16,285,379.21
1915	151,914,378	28,608,673.53
1916	195,157,773	55,265,255.05
1917	220,263,737	61,302,312.65
1918	185,253,715	45,725,120.02

(c) *Beer, Sondheimer & Co. (Inc.)*.—Beer, Sondheimer & Co. of Frankfurt established a New York branch in 1906. Like the Metallgesellschaft, it sent over two young men, Benno Elkan and Otto Frohnknecht, who established the business here under the name of Beer, Sondheimer & Co., American Agency. The name was subsequently changed to Beer, Sondheimer & Co., American Branch, and the business was conducted under that name until August, 1915, when it was incorporated, under circumstances which will be hereinafter discussed. The New York business was owned at all times by the Frankfurt house, Elkan and Frohnknecht being only agents upon a salary and a profit-sharing basis.

Like the parent company, Beer, Sondheimer & Co., American Branch, confined its activities mainly to dealing in zinc. It made contracts with various zinc-ore producers for their entire output, and in 1907 acquired a controlling interest in the National Zinc Co., which owned a zinc smelter at Bartlesville, Oklahoma, and had under lease another zinc smelter in Springfield, Illinois, and an acid plant at Argentine, Kansas. In 1908, Beer, Sondheimer & Co. obtained control of the old El Cobre copper mine near Santiago, Cuba. It organized a corporation known as Cuba Copper Leasing Co. to operate the mine in Cuba. In 1908, Beer, Sondheimer & Co. took a long lease of a copper smelter at West Norfolk, Virginia, and organized a corporation known as the Norfolk Smelting Co., through which it has been operating the copper smelter. The product of the El Cobre mine and such other copper ore as Beer, Sondheimer & Co. purchased was treated at the Norfolk plant.

In recent years Beer, Sondheimer & Co. has also become interested in the development of zinc mines in the Butte district. It has taken options on various mining claims in that district and has done considerable prospecting therein. The following tables show copper, spelter, and lead turnover of Beer, Sondheimer & Co. for several years:

List of Contracts for Zinc Ore

Name of seller	Commodity covered by contract	Tonnage delivered during 1914	1915	1916	1917	1918
Federal Mining & Smelting Co., Wallace, Idaho	Total output of zinc concentrate for 3 years from date of first shipment	4 799		.

MINERALS SEPARATION AGENCY

The history of Beer, Sondheimer & Co.'s activities in the United States would not be complete without mentioning its connection with the various Minerals Separation companies.

The various Minerals Separation companies have successively claimed to own patents covering an improved process of ore concentration. Ore concentration in metallurgical operations is the separation of the mineral or metallic part of the ore from the non-metallic or worthless material found associated with it in nature, in order that the valuable metallic particles may be in proper condition for the subsequent process of smelting.

Expressed in language that laymen can understand, this new process may be described as the addition of a very small quantity of oil to the ore-pulp (which is ore finely pulverized floating on water) followed by vigorous agitation of the pulp and the introduction of air-currents into the mixture resulting in the development and distribution throughout the mixture of small bubbles of air which attach to themselves the valuable metallic particles and with them rise to the surface forming a mineral froth of such coherence as to afford full opportunity for its removal from the surface for further treatment of the metallic particles, while the worthless material sinks to the bottom.

Prior to the invention of this new process, ore concentration, or the separation of the mineral from the useless parts in ore, was effected by the water or gravity process. In that process the ore was mixed with water forming the ore-pulp; the pulp was shaken, thereby separating the metallic particles from the worthless parts of the ore, and the metallic particles being heavier than the water, sank to the bottom, while the worthless particles being lighter than the metallic particles, though heavier than the water, were subjected to an up current of water which carried the worthless particles to the surface and over the container. The old process was commercially unsuccessful because it permitted a large percentage of the metal in the ore to be carried off with the worthless particles. The material thus rejected was called 'slime'. For years dumps consisting of millions of tons of such slime, which were known to contain a large percentage of metal, lay useless because there was no known process by which they could be treated and the metal extracted.

In 1906, H. L. Sulman, H. F. K. Picard, and John Ballot, all of London, England, claiming to be the inventors of the new process, obtained a patent thereon in the United States. In 1910, Sulman and H. H. Greenway and A. H. Higgins, all of London, obtained another patent in the United States, and in 1914, Greenway, then of Melbourne, Australia, obtained a third patent in the United States, the latter two patents involving the same process as the first one, but including improvements thereon. These patents run for a period of 17 years from their respective dates.

In 1905, and before the first United States patent was obtained, the patentees obtained a patent in England exactly similar to the first United States patent. The validity of the English patent was attacked in the English courts, but was sustained by the House of Lords. (Minerals Separation v. British Ore Concentration Syndicate, 27 R. P. C., 33.)

In 1903, Minerals Separation, Ltd., which will be hereafter designated as the parent company was formed under the English law. The three United States patents were assigned to this company. In 1910, the parent company having acquired the United States patents, and similar patents obtained in Canada and Mexico, conveyed these patents to a corporation called Minerals Separation Syndicate, for the purpose of enabling the American syndicate to exploit these patents in America. This, too, was an English corporation.

In 1911 the American syndicate made a contract with Beer, Sondheimer & Co., whereby it gave to that firm the exclusive agency to represent the syndicate in America. For reasons unimportant to the present inquiry, this first American syndicate was soon dissolved and a new syndicate was formed, called Minerals Separation American Syndicate (1913), Ltd. This, too, was a British company. The 1913 syndicate renewed the agency agreement of Beer, Sondheimer & Co., and appointed that firm sole agents to conduct all of the syndicate's commercial affairs in the United States, Canada, and Mexico, the agency to continue for a minimum period of 10 years with a provision for renewal for the rest of the life of the patents. Beer, Sondheimer & Co. were to receive a commission of 10% of all gross royalties received for the use of the patents and 10% on all profit-sharing business (the syndicate intending not only to give licenses, but also to buy up and treat ores), and also a percentage as a commission of the sale of products so treated by the syndicate.

When the agency agreement was made Beer, Sondheimer & Co. had an American branch of its business in New York City, which was in charge of Benno Elkan and Otto Frohnknecht, and was being conducted under the name of Beer, Sondheimer & Co., American branch. The parties entered into the performance of the agreement, and inasmuch as most if not all of the business was done in the United States the agent's end of the business was conducted by the American branch of Beer, Sondheimer & Co.

In addition to having the exclusive agency, Beer, Sondheimer & Co. were also stockholders of the 1913 syndicate, owning 32,615 shares of said stock. In 1916 the property of the 1913 syndicate was conveyed to an American corporation called Minerals Separation North American Corporation, and each stockholder became entitled to two shares of the American corporation's stock for each share of the 1913 syndicate stock.

The importance of the control by this German owned branch of Beer, Sondheimer & Co. of the Minerals Separation process, and the power to grant or withhold from the United States metal industry licenses to use the flotation process, can hardly be over-estimated. The Custodian, as will be pointed out later, has taken over all of the Minerals Separation stock held by Beer, Sondheimer & Co., and the latter's control of the Minerals Separation process in the United States has broken.

ARON HIRSCH & SOHN, AND CONNECTIONS

Who will say that these three powerful German-owned or German controlled companies were not a standing menace to the security of our domestic metal industry as well as to the development of our own commercial interests in Mexico and South America? It is no answer to the obvious potential power for evil which these companies possessed to point to the fact that since the European War the American Metals Co. has been entirely officered by Americans who have shaped the policy of that powerful organization, or to show that Vogelstein is a naturalized American citizen, or to remind us that Elkan and Frohnknecht, in control of Beer, Sondheimer & Co., are likewise American citizens—they were late converts to citizenship. The power lay in the hands of Hirsch & Sohn and Beer, Sondheimer & Co. and the Metallgesellschaft and its stepchild, Henry R. Merton & Co., at any time and all times to direct the policy of these American concerns. These outposts of German commercial aggression having gained a foothold in the United States, were gradually spreading into Mexico and South America, which are legitimate fields for our own commercial development. In Mexico today the American Metal Co. is second only to the American Smelting & Refining Co. in its control of the mineral wealth of that country. In Peru and Chile and in other parts of South America these companies not only control the output of mines and smelters, but the American Metal Co. also owns mining claims of great extent. With unlimited resources at their command, they bought up mines, financed and built smelters and refineries, bought and sold huge quantities of metals, organized and controlled their own transportation facilities, and even invaded the oil industry. With the controlling power of these great organizations centred in the hands of the Germans—knowing what we know about Germany and Germans—who will deny that they have been a menace to the country?

We are not alone in our fear of German commercial aggression, nor in our desire to eradicate the German influences. England has gone even further than we have. Finding that the Germans had practically complete control of the Australian metal output, the English courts have declared void as against public policy all contracts between the Germans and the Australian mines, and the English have now completely supplanted the Germans in control of Australia's metal industry. In the meantime, in 1918, England passed an act for the purpose of controlling the non-ferrous metal industry and required that all persons engaged therein should first obtain a license from the Board of Trade. Henry R. Merton & Co. were refused such license, and in consequence thereof that company, together with its subsidiary, the Merton Metallurgical Co., Ltd., have gone into liquidation.

France and Belgium are re-building their smelters and building new ones. And it may safely be assumed that German ownership in the French and Belgian smelters and refineries will never be restored to them. Thus cut off from their control of the Australian zinc ores and from the control of Belgian and French smelters, their world domination of zinc and lead has been irreparably shattered.

This brings us to a consideration of what effect our participation in the War has had upon the German-controlled American companies, and how we have endeavored to deal with them.

When the European War broke out, these three American branches of the German metal triumvirate found themselves cut off from their German principals. Germany was in great need of metals, especially copper, and at first the American Metal Co., Vogelstein, and Beer, Sondheimer & Co., as well as other large American selling agencies, sought to supply that need by making shipments to neutral countries, but destined for Germany. The British blockade, however, soon tightened and after some consignments were seized by the British, an agreement was entered into between the six principal American selling concerns—Vogelstein & Co. and American Metal Co. included—and the British Admiralty whereby the American copper selling agencies agreed not to ship any copper to any country except those allied with England, without special permission from the British authorities. It is believed that after that agreement had been entered into, it was scrupulously observed by the American Metal Co. and Vogelstein & Co. The year 1916 was a very profitable year for all three of these German metal concerns. The American Metal Co. made a profit of $7,000,000 during 1916. Vogelstein & Co. showed a profit of $3,000,000, and Beer, Sondheimer & Co. showed a profit of $2,000,000.

(To be Continued)

Correction. In our issue of March 22 it was stated that the quantity of graphite ore milled in Canada last year was 19,611 tons; this should have been in 1917. During 1918, the output of graphite was 3051 tons, valued at $270,051. There was treated a total of 9958 tons, which yielded 3162 tons of milled or refined graphite.

The Tennessee Copper & Chemical Corporation in 1918 made 283,092 tons of 60 sulphuric acid.

Grinding-Pebbles and Tube-Mill Liners

A falling-off in the production of pebbles and liners for use in tube-mills, as shown by final figures for 1918, compiled by the U. S. Geological Survey, reflects both uncertainty of market and changes in grinding practice.

Natural pebbles for grinding rock, ores, minerals, cement-clinker, and many other materials, were obtained in 1918, as in preceding years, from the beaches between Oceanside and Encinitas, San Diego county, California. According to reports received by the Survey, the entire output was marketed by Robert Burns & Co., Oceanside; the Pacific Coast Pebble Co., Encinitas; and Thebo & Tingman, Encinitas. The output of these pebbles in 1918 was considerably smaller than in 1917, probably in large part because the growing use of steel balls is supplanting the use of pebbles; but the decrease was due in part to the uncertainty of the market, which deterred pickers from collecting and sorting stocks that they might have marketed.

The output of artificial pebbles in 1918 was considerably greater than in previous years. These so-called artificial pebbles are either roughly cubical or mechanically smoothed and rounded blocks of quartzite manufactured by the Jasper Stone Co., Sioux City, Iowa; or mechanically smoothed and rounded blocks of silicified or chalcedonized rhyolite, manufactured by Omer Maris, Manhattan, Nevada.

In 1918, the sales of pebbles and of cubes and artificially-rounded blocks for use in grinding amounted to 9734 tons, valued at $82,350. This was a decrease, roughly, of 2300 short tons, or nearly 20%, compared with the sales in 1917. The value, however, shows an increase of nearly $24,000, or about 30%, compared with that for 1917. Besides this marketed output, there was an indeterminable consumption, probably large, of substitutes for grinding-pebbles by mills that used local pebbles, boulders, lumps of ore, or native rocks.

Only estimates are available to show the quantities of flint pebbles imported. The records of the Bureau of Foreign and Domestic Commerce indicate that the quantity of pebbles imported in 1918 was probably a little over 10,000 tons, about 70% of which came from Denmark, the remainder from France.

The total new supply of grinding-pebbles contributed to domestic markets in 1918 appears thus to have been 20,000 tons, compared with 25,500 tons in 1917, 32,000 tons in 1916, and 31,000 tons in 1915. This diminishing supply is evidence of the growing use of steel balls or other substitutes for grinding-pebbles.

The domestic output of flint or quartzite tube-mill lining in 1918 was 2535 tons, valued at $46,634, compared with 3050 tons, valued at $59,250, in 1917. In 1918 there were only two producers—the American Flint Co., Iron City, Tennessee; and the Jasper Stone Co., Sioux City, Iowa.

Powdered coal is being tested as fuel in blast-furnaces of the Tennessee Copper & Chemical Corporation.

REVIEW OF MINING

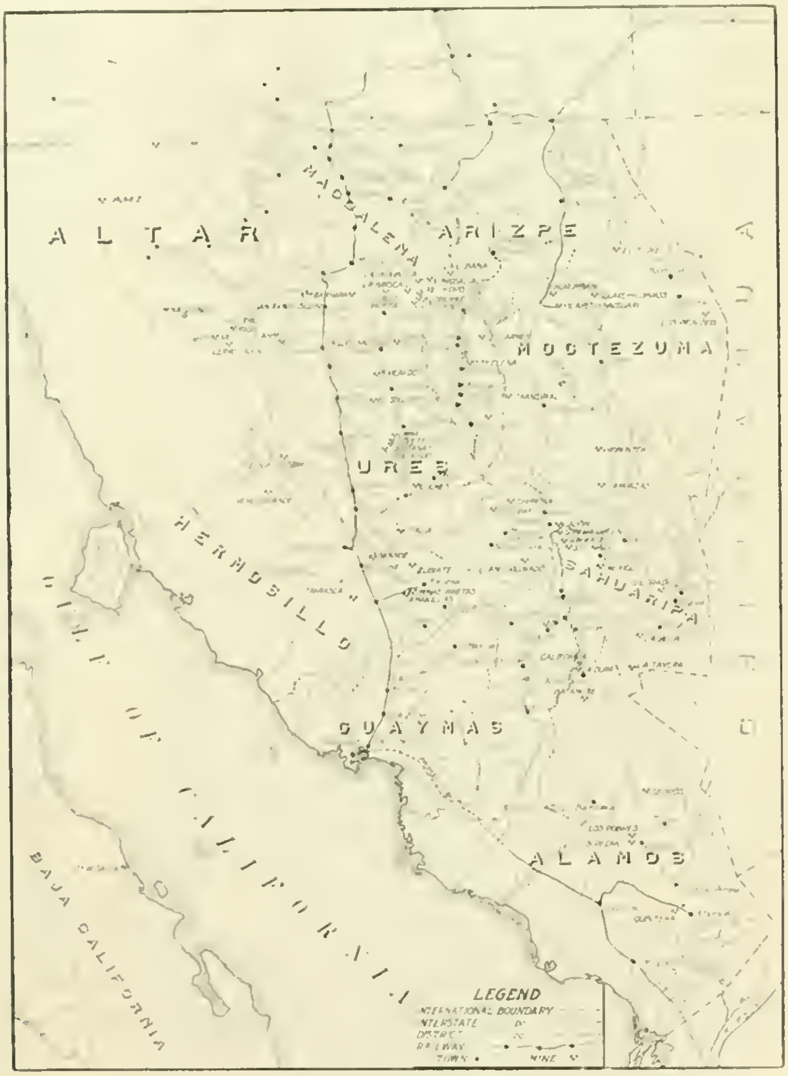
CANANEA, SONORA

PRESENT ACTIVITIES IN NORTHERN SONORA

Mexican (Sonora) ore shipments to the United States during March, through the 'port' of Agua Prieta, were 6238 tons, valued at $1,236,500. This is considered to be a little more than the average per month. Individual shipments were as follows, in tons: Moctezuma Copper Co., 5480; El Tigre, 159; San Pablo, 29; La Colorado, 13; La Caridad, 93; San Ygnacia, 63; La Escuadra, 10; San Nicolas, 39; Promontorio, 42; and Rosales, 10 tons. Much of the ore now being sent through this port is lead and silver-bearing. Reports from Nacozari and vicinity are to the effect that prospectors are crowding into the country in increasing numbers. While copper properties are not changing hands at present, there is a marked effort to get hold of silver mines, already developed or promising prospects.

At the property of the Nacozari Consolidated Copper Co. near Nacozari, the deep development tunnel had traversed the recently encountered copper zone for 73 ft. without apparent diminution in the amount or quality. Mining men who recently returned to Douglas state that a body of considerable magnitude is being developed. The management contends that as no pay-ore was expected before reaching the main vein, still several hundred feet away from the breast of the tunnel, the ore-zone is proving far more extensive than calculated. Machine-drills are in continuous operation, driving 8 ft. each 24 hours. The tunnel is now over 3000 ft. long. The copper minerals are chalcopyrite and bornite, similar to the higher grades of ore in the Pilares de Nacozari mine of the Moctezuma Copper Co., a Phelps Dodge holding. John G. Alexander, general manager for the Nacozari Consolidated, reports also that good progress is being made at the San Pablo, where work was recently recommenced. A new vein of high-grade silver ore was opened recently, adding considerably to the ore-reserves. The San Pablo is preparing to resume shipping silver ore to the El Paso smelter in the near future.

At Cananea, the only active copper producer at present is the Cananea Consolidated Copper Co., which is working most of its shafts on a small scale, having only watchmen and repair-gangs on duty at some of them. The smelter is working at quarter capacity. During the last month several hundred additional men were laid off. The company adopted the policy of supplying transportation to these men and their families to any point in northern Mexico they might wish to go. At least one special train carrying several hundred Mexicans left Cananea early in April for southern Sonora and Sinaloa points. Most of them chose the latter State, it being more largely devoted to agriculture, therefore affording a better opportunity to tide over the dull period in mining. By ridding Cananea of the unemployed surplus, the 'Four C' company has avoided repetition of political



THE STATE OF SONORA, MEXICO

and social unrest. The copper output in March was 3,200,000 lb., about half of normal.

Operations in the northern districts of Sonora are showing considerable revival with the opening of spring. Several deals of importance are reported to be pending, while a number of properties have been re-opened, and there is a growing demand for silver mines. A leader in importance among the newer properties is the San Nicholas, a silver property being operated by Leo G. Cloud and associates under the name of the Compania Mexicana Dessaralladora de Minas (Mexican Development & Mining Co. under a lease from the Transvaal company. The property lies 15 miles west of Cumpas, centre of the Moctezuma mineral district. Fairly good roads lead from it to Nacozari, the nearest rail point. C. N. Knutsen is resident manager. While the underground force is extracting ore for the small mill on the property, machinery has been ordered for a 50-ton flotation plant. This includes a K & K machine, a Marcy mill, and a Dorr classifier. Altogether the property is considered to have exceptionally good prospects, the ore being readily amenable to flotation. Shipments have been started and it is intended to send one carload of concentrate monthly for the present.

The Tepacate group, an old property in the vicinity of Bonamachi, has been taken over by the Hosier brothers, representing Kansas City capital. A gasoline hoist has been erected, and the old workings are being re-timbered. When this has been done a considerable amount of ore will be within reach. Experiments are being made on the ore to ascertain the best method of treatment, after which a mill may be built.

The Bavicanora group, adjoining the famous Las Chispas mine near Arizpe, has been taken over by F. Oldfield Bostwick and associates. This is one of the most important properties in the Arizpe district, having been opened first in the days of Maximillian, but later abandoned on account of the hostility of the natives. Latterly the workings within reach of the surface were gutted by 'gambocinos' (Mexican high-graders), and so much of the old timbering removed or rotted away that many of the drifts caved-in. When Bostwick took hold of the property considerable timbering had to be done, but the result was to make available considerable bodies of silver-gold ore. A 10-stamp cyanide mill has been erected, and while mechanical troubles have been frequent, the plant now is being adjusted. Mr. Bostwick has made some shipments of concentrate recently, which are understood to have netted him excellent returns.

Las Chispas mine, owned by the Pedrazzini interests of Switzerland, and managed by Antonio Pedrazzini, nephew of the principal owner, also has returned to work after a considerable period during which the management was at loggerheads with the Sonora government and that of Mexico over taxes and local conditions. These differences were adjusted some time ago to the satisfaction of both sides. The 20 stamp mill is in regular operation and shipments are being made at the rate of a carload of high-grade concentrate each month.

El Carmen mine, near Chinapa in the Arizpe district, is being re-opened by Louis Burgonia. The old shafts and drifts are being re-timbered and being put in shape. El Carmen yielded several hundred thousand dollars of silver in the 'seventies, but has been closed down for a number of years.

El Canario Copper Co., whose properties adjoin those of the Moctezuma, is working the Lillie group, 8 miles from Nacozari, on a considerable scale. The company is concentrating on development in shafts, tunnels, and drifts, and has blocked out a considerable tonnage of a good ore. A large compressor, hoist, and other machinery has been installed, while good roads have been built to Nacozari. Several motor-trucks are used to haul supplies between the railroad at Nacozari and the mine. These later will be used to carry ore to rail. The same company is working the Canario group, adjoining La Caridad mine, 18 miles from Nacozari. Development is the only effort at present, large bodies of copper ore being ready when market conditions warrant. J. P. Harvey is the manager, maintaining his residence at Nacozari.

A custom mill to treat ores of the district surrounding the Cinco de Mayo property at Pilares de Terras, is being erected on the Roy property, which is owned by the First National Bank of Douglas. This will help the district considerably. The mill is not the property of the bank mentioned, but is being constructed by arrangement with the bank. In the meantime, the Roy mine staff is getting out ore and stacking it preparatory to putting it through the mill when it begins work within the next few weeks.

OATMAN, ARIZONA

OPERATIONS IN THE OATMAN AND GOLDROAD DISTRICTS.

In addition to the steady operation of the United Eastern and Tom Reed companies, the Oatman district is showing renewed activity, especially in prospecting. ——The Red Lyon has begun cross-cutting south from the 220-ft. level.——The Telluride is down 20 ft. in a new shaft. This company will also continue prospecting from the old shaft at the eastern end of the property. ——The Lexington is cross-cutting from the 250-ft. level. The latest report is that the vein has been reached.——It is said that the Mushrush property, consisting of two well-located claims on the strike of proved orebodies, has changed hands, and will shortly be equipped and operations begun.——The United Oatman has reached a depth of 584 ft.——The Alcyone is driving on the 400-ft. level. ——The Lazy Boy is driving on the vein at 200 ft.——On the Blue Bird (Big Jim Con.) the shaft has reached a depth of 300 ft. An 18-ft. vein of calcite, dipping to the south, was encountered at 265 ft. Systematic cross-cutting and driving is planned when the 400-ft. level is reached.

In the Goldroad district the Gold Road Bonanza continues work at a depth of 550 ft.—A few men are employed at the Gold Ore.—The Goldroad mine is still inactive, although there is sufficient ore blocked out to run several years. It is reported that this company (the U. S. S. R. & M. Co.) will not resume operations during the present range of high prices.

MISSOULA, MONTANA

POSSIBILITIES OF GOLD MINING IN THE EAST COEUR D'ALENE REGION.

This region lies between Fish creek in the east of Mineral county and Saltese to the west in the same county, on the north slope on Coeur d'Alene range and that part of Idaho drained by the St. Joe river. The area is essentially gold-bearing, although a few copper and lead deposits have been found. In the 'seventies a number of large producers of placer gold was in operation, but the Frazer river and Cariboo excitement depleted the district of miners. In the early days it was only the shallow and rich ground that was worked; what did not yield $1 to $1.50 per yard was hardly considered. With the hydraulic giant, hydraulic elevator, and other placer machinery, a revival has gradually taken place. A small dredge was erected on Cedar creek, but it had to be abandoned on account of hard 'reefs' of bedrock, and ground too deep for its capacity. Several small hydraulic plants have been put in, but have generally been failures, being too small to work economically.

In 1917 a modern hydraulic plant was installed on Windfall creek by the Windfall Placer Mining & Development Co. This company owns 600 acres, which has been found to average better than 30c. per yard. The plant consists of a sawmill, 1¼ mile of flume carrying water to the penstock, from where a 24-in. pipe leads to the pit, giving a head of 375 ft. at the giants. There are two of No. 3 size, fitted with Hoskins deflectors. A hydraulic derrick, having a capacity of 3 tons has been erected to handle boulders. The ground is well suited for hydraulicking, having a good water-supply, plenty of dumping-ground, and a uniform grade of 6%, and in some places more. The gold is coarse and easy to save: it is high-grade, running 984 fine. This company under proper management should make a handsome profit on its investment. The equipment has been financed by local capital.

On Trout creek, one of the larger streams, there is about to be erected a large hydraulic plant financed by Eastern capital. The estimated capacity will be 3000 in. of water under 250-ft. head, handling 1500 yd. per day. It is claimed by the owner of the ground that the value will average over $1.50 per yard.

Some of the equipment for the Niagara Mining Co.'s placer mine on Niagara creek is at the railway station awaiting transportation over the mountain to its property. It is doubtful if the pack-trail will be open before the later part of May.

There are a number of good placer prospects where money could be made if properly equipped. In some places hydraulic elevators would have to be installed in order to handle the gravel. At other places dredges could be worked profitably, but capital is required.

In gold-quartz mining the east Coeur d'Alene offers good opportunities for exploration. A number of promising prospects can be found all along the range. The veins generally have a strike parallel with the main range—NW to SE. Veins are found in slate, porphyry, quartzite, and granite. Several of them carry fair value, and are remarkably persistent both in strike and dip. There is an abundance of water for power for all purposes. The field is well worthy of consideration by mining men, and it should in the near future prove to be one of great activity.

GOLDFIELD, NEVADA

PREPARATORY WORK FOR MINING LOW-GRADE ORE.

The Goldfield Development Co. has started a cross-cut at a depth of 380 ft. to connect the main south-east drift in the Combination with the Combination Fraction shaft, which will be the main working shaft for the glory-holing operations in this area. The cross-cut will be extended 300 ft. to the Fraction shaft, which is in good condition and will require little re-timbering. After the cross-cut is complete, the main drift will be widened to accommodate double tracks, and raises will be driven into the stope-filling at 25-ft. intervals. It is estimated that 1,500,000 tons of material assaying $5.60 per ton will be drawn from the vein south-east of the Combination shaft and north-west to the January shaft, a total diistance of 1000 ft. A concrete foundation is being laid for a hoist at the Fraction shaft, and within a few days construction of ore-bins will be started. The hoisting-plant of the Mohawk mine will be used, as its shaft is now useless. After a complete sampling of the Red Top it is calculated that 200,000 tons of material there will assay between $6 and $7 per ton, with a large area not developed by the Goldfield Consolidated company holding important possibilities. This tonnage was not included in the original estimates of the manager, A. I. D'Arcy, on the possibility of mining low-grade ore in the Consolidated. No repairs have yet been made to the Consolidated mill, where the ore will be treated, and none will be made until the mines have been placed in condition for production, as it is considered that few alterations will be necessary, and these will occupy little time.

SILVERTON, COLORADO

SUNNYSIDE COMPANY HAS DISASTROUS FIRE.

On April 21 fire started in one of the buildings of the Sunnyside M. & M. Co. and spread with such rapidity that in two hours property valued at $200,000 was destroyed. The new bunk-houses and commissary buildings, construction of which was recently completed, were totally destroyed, all wearing apparel and other personal effects of the miners being lost. The bunk-houses were considered to be the best in this State in respect to comfort and sanitation, and two years was required for their construction. The 300 men employed were deprived of quarters and are being temporarily accommodated at Eureka and Silverton. The compressor-house was totally destroyed and all the machinery ruined, with the result that all mining operations were brought to a standstill. The transformers were saved, and the flames were also prevented from reaching the tramway. As several months will be required to replace the buildings destroyed with even temporary structures, there is not much possibility of work being resumed by the company for some time.

This disaster has resulted in a surplus of labor in the Silverton district. Fortunately, Telluride is in need of miners and will absorb a large number of them.

DIVIDE, NEVADA

WHAT IS BEING DONE IN THE NEW DISTRICT.

Large numbers of persons—miners, would-be mine-owners, engineers, and promoters—are arriving daily at Tonopah from the north and south, answering the call of a mining boom that is assuming proportions rivaling that of Goldfield. Buildings are being hauled to or erected at Divide, but the only accommodations at present are at Tonopah, six miles distant, where the hotels and lodging-houses are congested and guests are compelled to 'double-up' in inadequate quarters. Locations nominally in the Divide district cover an area five by eight miles, and have been made nearly continuous to a point far south of Klondyke, or 10 miles south of the Tonopah Divide mine. A new gold discovery, half-way between Klondyke and Goldfield, bids fair to extend this area another seven miles to the south. Claims have been selling from $500 to $5000 each, even at a great distance from the central properties, and more than 150 companies have applied for charters. At least 50 of these have sold treasury shares at prices ranging from 5 to 15 cents each in sufficient number to give them substantial funds for development, these sums varying from $15,000 to $100,000. Deposits in two banks at Tonopah have increased approximately $3,000,000 within the past two months, representing funds realized from the sale of shares in Divide corporations. In view of the fact that there is little other than position on the map to recommend one claim over another, and in the absence of any proof that company funds are employed for other purposes than mining, there is no evidence of wild-catting in the Divide district. There have been patent instances of 'market rigging', however, by procuring fictitious quotations on stocks the majority of which is in pool. The stock exchanges have shown no inclination to discourage this practice, which has brought discredit and suspicion upon legitimate mining in the past. An authoritative analysis of the geology of the Divide district is still lacking, and much misleading publicity has been given to so-called geological reports that apparently have been designed to aid individual promotion schemes. The consulting engineer for the Tonopah Divide company, A. I. D'Arcy, has prepared a brief statement covering the central part of the district, a summary of this report appearing in the Press of January 25, 1919. This report is accepted as authentic for the area covered. Many of the successful operators, mine managers, and superintendents of Goldfield's active period are among the leaders in the Divide activity.

The shaft of the Tonopah Divide mine has been sunk to a depth of 565 ft., and a station at this point has been cut and timbered. The superintendent, William Watters, has completed massive foundations for a 1200-cu. ft. compressor and for a double-drum hoist, to be used after opening the next level. This work has delayed the starting of the fifth level cross-cut, which will now be driven to the silver vein. On the fourth level the main south-east drift, following the hanging wall, has advanced 250 ft., and the face is nearly under the rich area opened on the third level. The drift has continued in good ore, with face assays at times as high as 2000 oz. of silver. The richest ore is seamed with kaolin, containing slabs and flakes of pure horn silver. No cross-cuts have been driven on the fourth level, as efforts here have been devoted to driving to reach the high-grade area below the third level sill. The latter has been broken 50 by 20 ft. in extent, 10 ft. high, and all ore taken from this area averaged above $80 per ton. Raises from the second and third levels have connected with the levels above, providing good air, and other raises are being driven from these levels. All these raises have continued in high-grade ore, the third-level raise averaging over $70. Two sills have been cut to supplement, if necessary, ore from development work, the source of all production to date. Shipments to the MacNamara mill at Tonopah are 60 tons daily, transported by motor-trucks which have replaced the 8 and 10-horse teams. Mr. D'Arcy says that in order to secure the best extraction and lowest cyanide consumption he has endeavored to keep the mill-heads at $30, but the output of two recent days had an assay-value of over $70 per ton.

On the 500-ft. level of the Brougher Divide, the south cross-cut penetrated the vein for 30 ft., and a drift south-east was started without continuing to the foot-wall. The vein material was low-grade, but within a short distance ore appeared on the foot-wall side, and the drift was turned farther south and has progressed 140 ft. Most of this ore has been of milling grade.

The Gold Zone is preparing to sink from the 500-ft. level to a depth of 800 ft. The south-east drift and north-east cross-cut on the 500-ft. level have exposed seams of rich ore, the latter development being regarded as highly significant in view of the extensive faulting between the Gold Zone and Tonopah Divide workings. It is held that the newly-opened fissure or fracture-zone may prove to be the true Divide fissure.

The Hasbrouck has started shipping ore to Tonopah from the vein cut 400 ft. in the lower tunnel. At 950 ft., this tunnel has penetrated the main lode of the mountain, showing free gold 600 ft. below the apex. The shaft, 360 ft. deep, is being re-timbered and the old workings on the 200-ft. level, 260 ft. below the tunnel-level, are being re-opened. A drift on this level, driven about the year 1902 by John McKane, is said to have exposed a large tonnage of ore assaying from $15 to $26 per ton, with silver at 50 cents per ounce.

THE MINING SUMMARY

ARIZONA

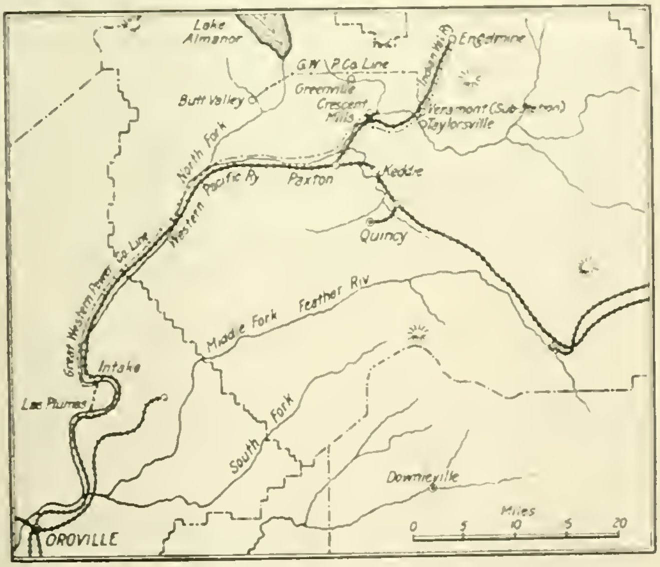
Globe.—The Arizona Asbestos Co. has resumed operations. Contracts have been let for haulage. The output of the mine is sold under contract with the Johns-Mansville company.

Jerome.—The United Verde Extension tunnel having drained the country around the Dundee-Arizona mine, the latter is to re-commence sinking immediately. This company has 50,000 tons of carbonate ore developed, and plans are being drawn for a leaching-plant to treat it.

Ray.—What appears to be the largest gold strike made in Arizona for some time is reported at Chelota, near Ray. Tho property on which the ore was found is being developed by New York capital. The vein is 24 in. wide, and specimens exhibited show large pieces of free gold. E. R. Tufts is manager.

CALIFORNIA

Englemine. The Engels Copper Mining Co. has issued its report for the first quarter of 1919. The income from sales of copper concentrate was $295,468, and operating expense $294,151, leaving a profit of $1317. The cost, excluding depreciation, was 16.68 cents per pound of metal; but in March this item was reduced to 15.19 cents. For 1918 the average was 19.58 cents. A reduction in power rates, from the Great Western Power Co., is probable. Storms in February cut off power for 5 days. Expenditure on No. 2 shaft, ore-bins, water-supply, mill, diamond-drilling, etc., totaled $34,693. Current assets are $401,864, and liabilities $244,023. Underground exploration was very satisfactory. On No. 6 level the last cross-cut passed through 70 ft. of solid bornite, averaging 5% copper. At least 500,000 tons were added to reserves, making them 2,775,000 tons. The metallurgical results were as under:



PART OF PLUMAS COUNTY, CALIFORNIA, SHOWING POSITION OF ENGELS MINE

	Engels mill	Superior mill	Total
Ore treated, tons	31,484	45,594	80,078
Copper content, per cent.	2.38	1.95	2.17
Concentrate shipped, tons	1,789	2,701	4,490
Copper content, per cent	29.39	23.02	26.20
Recovery, per cent.....	66.90	81.19	74.35
Copper paid for, lb	1,023,141	1,352,290	2,375,431
Silver, ounces	10,966	23,515	34,481
Gold, ounces	129	147	276

The large quantity of carbonate ore treated in the Engels mill, coupled with power troubles, resulted in the lower recovery.

Grass Valley.—The ore in the Golden Center mine in the centre of this town continues to improve, but the revenue comes principally from assessments.

The North Star and Empire mines are operating at full capacity of about 400 men each, despite the fact that a constant stream of men are leaving for Divide, Nevada.——The Brunswick remains closed, but the Orleans is being developed.

Igo.—Three thousand feet of 9-in. galvanized iron pipe was laid during April in the long tunnel in the Silver Falls silver claims near Igo, and by using a blower the workings have been ventilated so that the mine may be examined. The mine was closed 25 years ago, when silver was at a low price, so now that the metal is $1 per ounce an examination is to be made to determine whether it can be operated profitably. The group includes the Pilchuck, Richmond, Chicago, Cold Springs, and Union claims. They belong to F. M. Archer of San Francisco. The main tunnel, over half a mile long, is in good condition, no caving having occurred in all these years. All that is needed is ventilation.

Nevada City.—Logs are ready for raising the dam at the Liberty hydraulic mine, 7 miles east of this place. A spillway is being cut out with a monitor and by blasting. The mine is idle pending completion of the dam and erection of derricks for handling boulders.

Oscar Ford of Riverside has secured the contract for erecting a large concrete dam at Bullard's Bar across the North Yuba river, 20 miles west of Nevada City, for impounding tailing from Brandy City mines.

Shawmut.—In the Belmont Shawmut Mining Co.'s report for the 10 months ended December 31, 1918, the following information appears, written on March 1, 1919:

In June, mining and milling of ore was commenced, but after five months of adverse conditions, all work was suspended save development on the lower levels, No. 18. The mill treated 29,336 tons of ore averaging $4.90 per ton. The concentrate—3229 tons—contained 6418 oz. The extraction was 92.18%. The ratio of concentration was 9.08:1. Construction and improvements during the period cost $94,-962 and exploration $66,080. New openings totaled 2133 ft., 85% being below No. 16 level. Results were encouraging. Ore-reserves increased considerably to 424,733 tons. Wages for miners increased 26% and for mill-men and mechanics 38% over those of the previous year. These were not so serious as the decreased efficiency, namely, 65% of normal effort. The labor turnover underground was 280% in October. Mining supplies advanced 37.7%, water from 12½ to 37½ cents per inch, electric power 36%, and freight-rates 25%, also smelter charges. There is plenty of labor available now, and operations were expected to be resumed early in April. O. McCraney is superintendent and Albert Silver is in charge of the mill.

San Francisco.—The statistical division of the State Mining Bureau, under the direction of Fletcher Hamilton, State Mineralogist, has now received complete returns from operators on the output of a number of the mineral products for 1918. The data are given herein in advance of the main report, in order that those interested may receive the information at an early date. The date of publication of the final and complete bulletin on the mineral yield of the year is dependent upon the promptness of replies from operators. So far this season, most of the returns have come in earlier and in better form than in previous years; for which reason it is expected that the final bulletin will be issued earlier than usual. Some of the yields were as under:

	1918		1917	
Mineral	Tons	Value	Tons	Value
Asbestos	229	$9,903	136	$10,225
Borax	88,772	1,867,908	109,944	2,561,958
Cement, bbl.....	4,772,921	7,969,909	5,790,734	7,544,282
Magnesium salts.	1,008	29,955	1,064	34,973
Pyrite	131,029	425,012	111,325	323,704
Pumice	2,114	28,669	525	5,295

Most of the asbestos came from Nevada county. The pyrite came from two mines in Alameda, and one each in Eldorado and Shasta. The pumice was mined in Siskiyou and Imperial counties.

COLORADO

Boulder.—The Chamberlain sampler here, re-opened by the Boulder Ore Sampling Co. early in March, handled over 400 tons during the first month. The business is growing steadily.

Idaho Springs.—The Argo tunnel and mill are idle for the present.

Leadville.—The Derry Ranch Gold Dredging Co., in charge of Robert F. Lafferty, re-started its boat on April 20, after being closed for four months during the winter. This company finds it more profitable to stop work in the winter than try and operate. This is the fourth season of dredging, the previous three being highly profitable. A. C. Ludlum, president of the New York Engineering Co., is the principal owner.

Telluride.—The leading companies of this district have agreed to increase the price of board to $1.35, a 35-cent advance over the prevailing scale, to take effect May 1. The operators have been losing an average of 50 cents a day on the present basis, and the increase will, in a measure, offset the high cost of operating.

An important development is the change in the control of the Black Bear mines. These holdings of the Smuggler Union Mining Co. were formerly operated by a leasing company, but are now to be under the direct operation of the Smuggler Union. The Black Bear is across the range from the main workings of the Smuggler Union, and is believed to have a continuation of the main orebodies, although of a much lower grade and carrying more copper, it is generally similar to that of the main deposits. A tramway connects the Black Bear workings with the Smuggler Union mill. The property is well opened up by four levels, shafts, chutes, and manways. Extensive development was started early in May with the object of shipping larger tonnages this season

IDAHO

Osburn.—While there is not much mining activity in this district at present, there are said to be silver deposits worth attention. The Silverado, Nellie, Mineral Point, and one or two other mines are working. The first-named has a mill.

MISSOURI

Joplin.—Production of the Tri-State region last week was as under:

State	Blende, tons	Calamine, tons	Lead, tons	Value
Kansas	1,476	...	384	$75,457
Missouri	997	415	116	.....
Oklahoma	6,440	...	616	278,600
Total	8,913	415	1,116	$407,432
Previous week ...	7,744	252	974	370,848
Average per ton..	$37	$27	$55	......
Previous week ...	39	27	60	......

NEVADA

Ely.—Nevada Consolidated in 1918 made a profit of $3,402,070, about one-third of that of 1917. The mill concentrated 11,650 tons of ore daily, the concentrate containing 76,607,062 lb. of copper. Costs rose from 11.68 to 16.60 cents per pound.

Goldfield.—All shares offered by the Goldfield Development Co. have been subscribed, and the books are closed, according to the announcement of the secretary, H. G. McMahon. The offering of 1,500,000 shares was limited to Goldfield Consolidated and Goldfield Development holders

A raise from the 910-ft. level of the Spearhead has cut the shale-latite contact at a height of nearly 150 ft. Ore was not found on the contact. Another raise has been advanced 30 ft. in a seam of ore of erratic value near where the 150-ft. raise was driven, and small quantities of ore of shipping grade are being saved at this point.

Jungo.—D. J. Sullivan of Lovelock has purchased the Black Diamond mine from Frank Carpenter for $10,000. The mine is in the Antelope range and has been undergoing development several years. Gold, silver, and some lead are the important metals.

Mina.—The Simon Lead Mines Co. has sunk its shaft to the 400-ft. level. A large tonnage of good ore is blocked out at 300 feet.

National.—The National Treasure Co. has resumed operations on gold-silver ore. A complete plant was erected at the property last summer by Utah people. J. A. McAllister is general manager.

Under management of Hon. W. J. Bell, the Buckskin National Co. is preparing for operations. The mine has been developed to a depth of over 400 ft. by a shaft, the orebodies have been opened for 3500 ft. by drifts and crosscuts, and 3000 ft. from the main workings the same vein-system has been opened by lessees. At the Halcyon lease, at the north end, development is to be resumed.

UTAH

Alta.—The Greater Consolidated Mines Co. has erected a motor-driven, 10 by 12-in. compressor. Three shifts, with a total of 25 men, are soon to be driving the tunnel a distance of 4 miles to cut several ore-bearing fissures. The portal is at an elevation of 7200 ft. A small tunnel is already in 100 ft., but this is to be enlarged to 8 by 9 ft. with a ditch.

Newhouse.—Operations of the Utah Leasing Co., which consisted in treating tailing from the old Cactus mill, has been completed. The venture was somewhat remarkable, as there was treated profitably 700,000 tons of material assaying slightly under 0.7% copper. The method of treatment employed was oil flotation, and the work extended over a period of 3½ years.

PERSONAL

Note. The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Abbot A. Hanks is in New York

John W. Finch, of Denver, has returned to China

Rensselaer Toll is in the Fresno district of California

Richard Roelofs was in San Francisco this week, on a holiday.

E. C. Homersham has returned from Johannesburg to London.

Bancroft Gore has returned from South America, and is now at Boston.

Thos. H. Leggett was in San Francisco last week, on his way from New York to Oregon.

Harold Cogswell, Captain in the 316th Engineers, has returned from France to San Francisco

C. W. Purington is at Shanghai. He will remain in China three months, returning to Vladivostok in September, and home by Christmas.

Robert E. Cranston has returned to San Francisco from Washington after serving with the U. S. Food Administration for seven months.

Ralph T. Mishler, resident manager for the Tigre Mining Co., in Sonora, Mexico, has returned to the mine after a short holiday in California.

James O. Greenan, Lieutenant in the 27th Engineers, formerly superintendent for the Olympic Mines Co. at Mina, Nevada, has returned from France.

Fred W. Denton, consulting engineer for the Copper Range properties in Michigan, now residing in Boston, has been at Houghton on a visit of inspection.

H. H. Adams, formerly with the Utah Leasing Co., at Newhouse, is spending a month in California, after which he goes to Arizona. His work in Utah is finished.

H. H. Burhans, formerly first lieutenant with the 316 Engineers, recently returned from France, and is superintendent for the Montana Yukon Mining Co., in the Yukon.

D. W. Shanks, Walter Parsons, and **E. F. Waldner** have gone to the Rio Plata mine in Chihuahua, Mexico, as manager, mine superintendent, and mill superintendent, respectively.

F. G. Lasier, Captain of Engineers, who has been stationed in Washington in the Office of the Chief of Engineers, has received his discharge and will resume his consulting work at Detroit.

A special meeting of the Montana Section of the A. I. M. E. was held at Butte on May 2. There were present **James F. Kemp** and **Charles K. Leith**. Mrs. J. F. Kemp spoke on the purposes and plans of the Woman's Auxiliary.

William H. Schact, general manager for the Copper Range Co., delivered a lecture to students at the Michigan College of Mines on the steam regenerating-system in use at the Champion copper mine. **James MacNaughton**, vice-president of the Calumet & Hecla delivered a lecture on practical improvements in underground haulage.

In co-operation with the U. S. Bureau of Mines and the Idaho Bureau of Mines and Geology, the University of Idaho at Moscow offers in the School of Mines a number of fellowships. These fellowships are open to college graduates who have had good training in mining, metallurgy, or chemistry, and who are qualified to undertake research work. The income of each fellowship is $720 per year for the twelve months beginning July.

Obituary

George Ferdinand Becker died in Washington on April 20, at the age of 72. He was born in New York City and was the son of Alexander Christian Becker, of Denmark, and Sarah Cary Tuckerman Becker, the daughter of the Rev. Joseph Tuckerman, of Boston. Dr. Becker was the last member of the group of distinguished geologists who in 1879 were associated with Clarence King at the time of the organization of the U. S. Geological Survey. He was a leader in mining geology and geophysics, and for many years had been the chief of the division of chemical and physical research in the Geological Survey. The investigations under his direction led to the establishment of the Geophysical Laboratory of the Carnegie Institution of Washington. Dr. Becker was a graduate of Harvard, he received the degree of Doctor of Philosophy at Heidelberg, and later graduated from the Royal School of Mines at Berlin. He was for four years an instructor of mining and metallurgy in the University of California, from which he came to the U. S. Geological Survey. He was one of the pioneers in governmental efforts to guide and encourage the development of the mineral resources of the West. In 1880, when the entire technical staff of the Geological Survey was utilized by the Bureau of the Census in taking the census of mineral production, the statistical work west of the Mississippi river was placed in Dr. Becker's charge. A little later his personal solicitations before a committe of Congress were largely responsible for the permanent establishment, under the auspices of the Geological Survey, of the annual statistical canvass of the mineral industry of the country now carried on by the Division of Mineral Resources. In 1880 he began the study of the geology of the famous Comstock silver lode, which, even at that time, had yielded $325,000,000 in bullion and is imperishably associated with some of the most romantic episodes in American mining. The results of this work were published in monographic form in 1882. The summers of 1883 to 1885 were spent by him in the study of the quicksilver deposits of California, and in connection with these studies a visit was made by him to the famous old Almaden mine in Spain. He was one of the pioneers in geological work in the coalfields and gold districts of southern Alaska, which he visited in 1895. His geological observations and studies were not, however, confined to the United States, for in 1896, under the auspices of an English company, he visited the Rand goldfield in South Africa, some of his observations there being later published by the Geological Survey. In 1898 he reported to the Military Governor of the Philippines as geologist and spent 14 months in the islands. Although prevented from accomplishing much in the way of active field-work because of the hostile attitude of the natives, he was able, during that period, to compile a useful review of the geology of the islands as known at that time. In connection with this Philippine service Dr. Becker prepared a special report for President Roosevelt on the desirability of scientific explorations in the Philippine Islands. He also rendered national service in the Canal Zone as a member of a special committee under the auspices of the National Academy of Sciences, for the purpose of investigating the geologic phases of the engineering problems of the Panama Canal.

Dr. Becker was a member of the National Academy of Sciences, the Washington Academy of Sciences, the American Institute of Mining Engineers, and the Metropolitan and Chevy Chase clubs. In 1911 he was elected president of the Geological Society of America. He was the author of more than a hundred scientific papers, and exercised a wide influence in the development of geological science, more particularly the interpretation of physical phenomena. G. O. S

THE METAL MARKET

METAL PRICES

San Francisco, May 6

Aluminum-dust, cents per pound	50—60
Antimony, cents per pound	8
Copper, electrolytic, cents per pound	15¼
Lead, pig, cents per pound	5¾—6¾
Platinum, per ounce	$100
Quicksilver, per flask of 75 lb	$75
Spelter, cents per pound	8
Zinc-dust, cents per pound	12½

EASTERN METAL MARKET

(By wire from New York)

May 6.—Copper is inactive but firm. Lead is quiet and lower. Spelter is dull and weak.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, to May 5, 1919, the United States government paid $1 per ounce for all silver purchased by it, fixing a maximum of $1.01½ on August 15, 1918. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last time being on March 25, 1919, on account of the low rate of sterling exchange, this resulting in daily fluctuation. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

On May 5, restrictions on the export of silver and fixed price of $1.01½ per fine ounce were removed by the Federal Reserve Board, thus establishing a free market for silver in the United States and throughout the world. The secretary of the Treasury does not contemplate any further sales of silver under the Pittman Act, except to the Director of the Mint.

Silver valued at $8,424,000 was shipped from San Francisco to the Orient on the 'Venezuela' on May 3.

COPPER

Prices of electrolytic in New York, in cents per pound.

TIN

Prices in New York, in cents per pound. The monthly averages in 1918 are nominal. On December 3 the War Industries Board fixed the price to consumers and jobbers at 72½c. f.o.b. Chicago and Eastern points, and 71½c. on the Pacific Coast. This will continue until the U. S. Steel Products Co.'s stock is consumed.

The zinc-ore market at Joplin, Missouri, is reported to be in a deplorable condition. The price of concentrate last week, basis of 60% metal, was $37 per ton, a drop of $2 in the week.

PRICES OF METAL PRODUCTS

Pig-iron, composite of 8 Eastern brands, per ton	$28.0350
Scrap machine castings, per ton	22.00—23.00
Scrap car-wheels, per ton	22.00—23.00
Scrap heavy melting steel, per ton	12.00—13.00
Steel plates, per lb	0.0265
Steel pipe, ¾ to 3 in. black, per lb	0.0415
Steel wire nails, per lb	0.0325
Finished steel, composite of 7 products, per lb	0.0325
Copper sheet, hot rolled, per lb	0.2250
Copper rods, round, per lb	0.1925
Brass rods, high and low, per lb	0.1775—0.2125
Bronze rods, per lb	0.2275
Lead sheets, full, per lb	0.0775
Zinc plates, per lb	0.0900
Zinc sheets, per lb	0.1000

Eastern Metal Market

New York, April 30

All the markets are stagnant and generally inactive, but prices hold fairly well. The steel price tangle is generally blamed for the poor demand for non-ferrous metals

Antimony is quiet and firm.

Copper demand continues light, but quotations are steady

Lead is flat, with a tendency to softness

Tin continues under Government control, and there is almost no trading.

Zinc demand is absent, but prices have remained fairly firm

ANTIMONY

There is little change, but it is for the better if anything Prices are a shade firmer at 6.62½ to 6.87½c., New York, duty paid, for Asiatic grades for wholesale lots for early shipment

ALUMINUM

Prices as quoted are slightly higher at 31 to 33c. for No. 1 virgin metal, 98 to 99% for early delivery. Re-melt metal of the same purity is about 2c. per lb. lower. The market is quiet

COPPER

Lack of demand continues to characterize the copper market. The past week witnessed no improvement over conditions reported in this letter a week ago, and consumers manifest no desire to enter the market except for immediate needs. The steel-price situation is blamed for the lack of interest in this market as well as in most of the other non-ferrous metals, but it is probable that consumers' needs have been largely provided for well into May, and there is no need for anxiety. Quotations are largely nominal at 15.25c., New York, for electrolytic copper for early delivery, with Lake at 15.50c., New York. Some Lake changed hands at this price during the last week. Production is still fairly heavy, it is believed, at least in excess of present consumption. Fundamental conditions are considered sound Casting copper is ½c. below electrolytic.

LEAD

The market is flat and stale, with almost no transactions reported. Quotations are unchanged at 4.95c., New York, in the outside market and 4.70c., St. Louis. The American Smelting & Refining Co. still maintains its New York quotation at 5c., with St. Louis at 4.70c. The tendency is soft if anything, and it is believed that a slight cut in these prices is possible, though it has not transpired so far. Some sellers are impatient, but the concensus of opinion is that there is nothing to be gained by forcing the issue. It is generally admitted that production is still in excess of demand.

IRON AND STEEL

Producers see little indication of good business in the next two months, and some expect little improvement before the fall, although business in several finished steel lines has picked up some in the past week. In the trade at large, disappointment rules because the country has not been notified decisively how the price matter stands or because some decision has not been reached. As to railroad buying, the Administration announces that it is not delaying purchases to force down prices, but is using up surplus material piled up during the War. This confirms steel producers in the belief that in any event such buying would not be large. Operations in the Chicago district average 60% of capacity, in the Youngstown district 45 to 50%, and in eastern Pennsylvania 40%.

TIN

The tin market is enjoying (?) the distinction of being the only Government controlled market, and it is laboring under a decided disadvantage. There is no certainty as to when import restrictions will be lifted, and now the rumor is revived that they will not be removed even after the U. S. Steel Products Co. has distributed all its allocated metal. It is stated that restrictions will continue until the Government metal has been largely consumed. This state of affairs make for dissatisfaction and discontent, and the future position is demoralizing. It is stated that some consumers have large stocks of tin which they cannot sell because of the restrictions and cannot sell as tin-plate because of lack of demand; they are still compelled to take allocated metal. Opinion still prevails that June 1 or soon after will see an end of import restrictions. An interesting fact is that during the past week a sale has been made of Straits tin from abroad at 48.25c. per lb. for shipment when restrictions are removed. There have been no arrivals of tin reported at Atlantic or Pacific ports so far this month. Straits tin in London was quoted at £227 per ton yesterday.

ZINC

The situation shows no improvement, and consumers are still absenting themselves from the market, except for such small quantities as they need at once. The steel-price muddle is the restraining influence, particularly in this market, as galvanizers are nominally heavy buyers of spelter. Prices have held well in the last week, generally at 6.05c., St. Louis, but today quotations are made at 6.02½c., St. Louis, or 6.37½c., New York, for prime Western for early delivery, at which price at least one sale was made. Some think that 6c. St. Louis could be done. Production is still in excess of demand, it is said, and no marked improvement is looked for until steel prices are settled and buying sets in. There has been some speculative buying around 6 to 6.10c., St. Louis.

ORES

Ferro-chromium: This product, containing 60 to 70% chromium, is quoted at 34c. per lb. for 4 to 6% carbon and at 32c per lb. for 6 to 8% carbon material in carload lots, with 2c. per lb. added for less than carloads.

Manganese: Imports in March are officially reported as 18,238 long tons, bringing the total for the first quarter to 115,321 tons, a large amount under present conditions in the ferro market. These imports contrast with 118,536 tons for the first quarter in 1918. Indian ore is offered at 55c. seaboard, but no sales of any ore are reported.

Manganese-Iron Alloys: Re-sale carload lots of ferro have gone at $110, delivered, in the last week, but domestic producers still quote $150, delivered, for 78 to 82% alloy, with $2 per unit deducted under 78%. Imports in March were 5741 tons, making the total for the first quarter 9211 tons, against 6022 tons for the first quarter of 1918. Spiegel is nominal at $37.50, delivered, with almost no business or inquiry.

Molybdenum: The market is dead, and prices are nominal with no interest manifested.

Tungsten: Some Chinese ore is reported to have changed hands at $7 per unit for spot delivery. High-grade scheelite and wolframite is quoted at $10 per unit. The future of the market is regarded as somewhat dependent on the settlement of steel prices. There are quotations of $1.50 per lb. of contained tungsten in ferro-tungsten, but it is likely that this could be substantially shaded.

Company Reports

UNITED STATES SMELTING, REFINING & MINING CO.

Property: mines and works in Arizona, California, Chicago, Colorado, Kansas, Mexico, New Jersey, Oklahoma, and Utah.

Operating Officials: Frederick Lyon, vice-president in charge of operation; S. J. Jennings, vice-president in charge of exploration and mining investment; G. W. Heintz, vice-president and general manager of western operations; D. S. Calland, vice-president and general manager of operations in Mexico; F. Y. Robertson, vice-president and manager of metal sales.

General Officials—A. P. Anderson, consulting mining engineer; C. F. Moore, consulting engineer; G. W. Cushing, traffic manager.

U. S. S. R. & M. Co.—C. E. Allen, manager of mines, Utah; G. W. Metcalfe, manager Mammoth plant; R. E. Hanley, general superintendent Mammoth mines; J. H. Kervin, superintendent Mammoth smelter, California; L. D. Anderson, manager Midvale smelter, Utah; O. J. Egleston, chief engineer; Ambrose Nord, cashier, Salt Lake City; D. R. Muir, manager Gold Road and Needles properties, Arizona; D. D. Muir, Jr., manager zinc mines and smelters; J. F. Barnard, superintendent, Bingham mines; and A. P. Mayberry, superintendent, Centennial Eureka mine, Utah.

Richmond-Eureka Mining and Niagara Mining Companies G. W. Heintz, general manager; and C. E. Allan, manager.

Compania de Real del Monte y Pachuca—Salvador M. Cancino, president; and D. S. Calland, director.

U. S. Metals Refining Co.—F. Y. Robertson, vice-president and general manager; R. W. Deacon, superintendent copper refinery, Chrome, New Jersey; William Thum, superintendent lead refinery, East Chicago, Indiana.

United States Fuel Co.—R. M. McGraw, general superintendent.

Utah Railway Co.—G. S. Anderson, vice-president and general manager.

The Sunnyside Mining & Milling Co. M. H. Kuryla, manager.

United States Stores Co. J. H. Horlick, manager.

Financial Statement: the net earnings of all companies in 1918, after charging cost of production, selling expenses, repairs, interest, depreciation, and depletion, was $4,775,090. Adding the previous balance of $13,004,970, there was available $17,780,060. After paying dividends there remained a surplus of $14,322,260. Current assets, including cash, bonds, metals, and products, total $18,476,191, and liabilities $7,995,341, including $864,450 for the dividend on January 15, 1919.

Dividends: preferred stock received $1,702,225, equal to 7%; and common stock $1,755,575. At March 31, 1919, there were 9499 preferred and 26,344 common stockholders.

Production: metals from all sources were as follows: copper, 20,359,378 lb.; gold, 137,315 oz.; lead, 96,567,485 lb.; silver, 15,337,465 oz.; and zinc, 18,771,684 pounds.

The tonnage of ores produced from Centennial-Eureka, Mammoth, Naylor, Ritz, Sunnyside, and Bingham mines, also in Mexico, was 1,220,722, of which the value of the metal contents was in the proportion of 10% copper, 10% lead, 7% zinc, 61% silver, and 12% gold

The coal output was 1,272,081 tons, a gain of 363,443 tons.

Mines in Arizona

The Gold Road mine near Oatman was shut-down on account of abnormal conditions.

Mines in California

Ore-reserves were maintained at the Mammoth The Friday Lowden orebody is developing into one of considerable importance. The Mammoth and Section 29 sent 77,695 tons of ore to the smelter at Kennett.——Exploration in the Stowell was not encouraging, so work was suspended.

The Keystone mine was purchased in November, owing to favorable drilling results. A 1004-ft. tunnel was driven and raising to the ore is progressing.——The smelter reduced 413,082 tons of charge from all sources, 236,142 tons of which was sulphides. At the electrolytic-zinc plant a new process is being tried.

Mines in Colorado

The Sunnyside property, at an elevation of 12,000 ft. in San Miguel county, is now prepared to produce 500 tons of ore daily for the new mill. [A disastrous fire at the mine on April 21, 1919, has delayed operations indefinitely.]

Mines in Kansas

At the Naylor zinc tract, developments were good, but prices for concentrate sold in the open market were low.

Mines in Mexico

At Real del Monte y Pachuca, the two mills will soon be able to treat 80,000 tons of silver ore monthly. A third one of 15,000 tons capacity for ore from the 'new' vein is under consideration. This orebody contains a large tonnage of high-grade and good milling ore.

Mines in Oklahoma

The Ritz zinc mine continued to open favorably, yielding good ore.

Mines in Utah

The Bingham mines shipped 41,661 tons of copper and 127,560 tons of lead ore. Reserves were materially enlarged. ——The Centennial-Eureka yielded 29,558 tons of ore. While no large deposits were found, a moderate amount of new ore was opened.——The Richmond-Eureka remained closed.—— The lime quarry supplied 90,526 tons for the Midvale smelter in Utah. Another blast-furnace was added to this plant, making seven.

Refineries

The lead refinery at Grasselli, Indiana, and the copper refinery at Chrome, New Jersey, operated to the full limit of their enlarged capacities under great handicaps.

Mining Decisions

Grant of Coal—Injury to Surface

Where a grant of coal underlying the surface provides that the grantee may enter upon the lands and mine and remove coal without any liability for damages from the exercise of such rights, he is not liable for injury to the surface by mining operations.

Weakland v. Cymbria Coal Co. (Pennsylvania), 105 Atlantic, 558.

Mining Agreement—Construction

A mining agreement contained an option to purchase, but also provided that the consummation of the purchase should not affect a certain lease in force between the parties. Held, that the lessee by exercising his option to purchase and depositing the full amount of the purchase price to the lessor's credit could not relieve himself of the obligation to pay the balance of the rent due up to the expiration of the term of the lease, but that the lessor's remedy lay in damages, and he could not evict the lessee by unlawful detainer proceedings for failure to pay the rentals, as the lessee was entitled to possession when he became a purchaser.

Rayburn v. Stewart-Calvert Co. (Washington), 178 Pacific, 454 and 455 February 14, 1919.

Prices of Chemicals for Five Years

The Year-Book of the 'Oil, Paint and Drug Reporter' of New York for 1918, a valuable reference of 321 pages, contains the following comparative figures, prices in cents per pound

INDUSTRIAL CHEMICALS

	1914	1915	1916	1917	1918		1919
	August	January	January	January	January	December	April 14
Alum, ground	1¾—2	2⅜—2¾	4¼—4⅝	4½—4⅞	4¾—5¼	5¼—6¼	4½—5

Book Review

Applied Mechanics. By Charles E. Fuller and William A. Johnston. Volume II—Strength of Materials. Pp. 538, ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, $3.75.

This is a text-book prepared by two members of the faculty of the Massachusetts Institute of Technology. It is a good text-book, and makes no claim to be anything else. The mathematical discussion of the various principles involved is complete, and it is illustrated at the end of nearly every chapter by a number of problems. The student may however, be disappointed to find that few of them are worked out for him, neither are there any 'answers' in the back of the book. The scope may be judged from the chapter headings, which are Physical Properties of Materials, Analysis of Stress and Strain, Uniform Stress and Uniformly Varying Stress, Stresses in Beams, Deflection of Beams, Continuous Beams, Combined Stresses, General Theory of Flexure, Columns, Shafting and Springs, Curved Bars and Reinforced Concrete Beams and Columns.

INDUSTRIAL PROGRESS

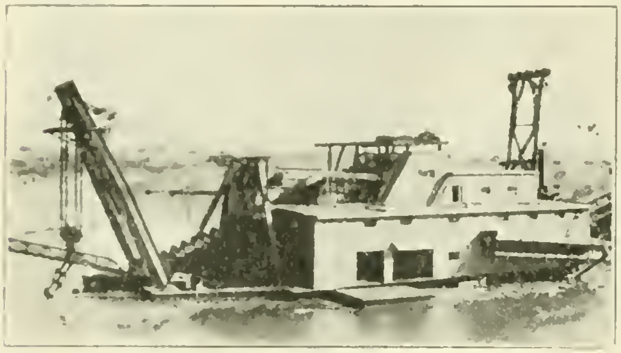
INFORMATION FURNISHED BY MANUFACTURERS

DETAILS OF A MODERN DREDGE

The dredge shown in the accompanying illustration was built and designed by the Union Iron Works, San Francisco, for the Marysville Dredging Co. in 1914. It has 16-cu. ft. buckets arranged to dig 70 ft. below water-level, also a 20-ft bank above water.

The general dimensions of the hull are as follows: length, 155½ ft.; width, 58 ft.; and depth, 11½ feet.

The digging-ladder is of the solid-girder type, 133 ft. long and weighs 126 tons, without rollers, buckets, or tumbler. The stacker-ladder is 146 ft. long, and is of the lattice type. The upper deck of the stacker-ladder is made in the form of an inverted V, so that material spilling off the belt does not collect thereon, but drops into the pond.



THE MARYSVILLE DREDGING CO.'S BOAT ON THE YUBA

The revolving-screen is 9 ft. diameter and 50 ft. long, with perforated holes varying from ¼ to 3/16 in. The weight of the screen is 70 tons, and is driven at the lower end by one roller, there being two guide-rollers to keep this central over the drive-roller; in other words, one roller carries a weight of approximately 35 tons plus the weight of the material being washed, which would easily amount to another 25 tons.

The buckets are of manganese steel throughout and weigh complete with lip 3880 lb. Theoretically, they hold 16¼ cu. ft. The pins are 7½ in. diameter, and are of special alloy steel, properly heat treated. Each pin is tested for hardness with the Shore scleroscope.

The upper tumbler is six-sided, cast integral with the shaft, and of nickel-steel. Bearings are 18 in. diameter by 30 in. long. This casting weighs 22 tons before machining. The tread-plates are of special forged steel, as manganese flows too readily under this load. The upper tumbler is driven by two spur-gears, each 14 ft. diameter and 15-in. face, one on each side of the shaft. The intermediate gearing has herringbone teeth. There is an equalizing device so that the load on both bull-wheels is equally divided. All the main drive gearing is of cast steel with cut teeth.

The main motor is 400 hp., and is belted to the main drive pulley, which is 12 ft. diameter with a 36-in. face. This is of the solid type wood construction, the same as used for stamp-mills. The main drive motor also operates the main ladder-hoist, there being two V-type clutches permitting either, or both, to be operated at the same time. The brake bands on the ladder-hoist drum are compounded off the countershaft. The main winch has eight drums, all friction driven by means of internal expanded bands. There is a speed-change device so that the drum can be thrown into high or low gear without stopping the winch. No jaw-clutches are used on any portion of this winch. Further, the two forward drums that do 90% of the work of the dredge are made the full width of the winch, this increasing the life of the swinging-lines easily 90% as the rope fleets evenly.

The steel spuds for holding the boat to its work are 60 in. deep and 38 in. wide. Each spud weighs 45 tons and is made of four Bethlehem 30-in. 180 lb. per foot I-beams, with 1¼ by 38-in. cover-plates, all bolted together with fitted bolts, no rivets being used in this work. The point is of cast steel and weighs 13 tons.

The water used for gold-saving purposes is supplied by two 14-in. pumps, one high pressure 72-ft. head, the other low pressure 40-ft. head, each pump delivering about 5500 gal. per min. There is also one jet-pump used for washing out the buckets, save-all, etc., which is a 6-in. two-stage pump and delivers 1000 gal. per min. The gold-saving tables are laid at a grade of 1 in. per foot and are lined with wooden riffles shod with iron. The total area of the tables is 8064 square feet.

The motors for the various parts of the dredge are as follows: main drive, 400 hp., 505 r.p.m.; main winch, 50 hp., 570 r.p.m.; high-pressure pump, 150 hp., 600 r.p.m.; low-pressure pump, 75 hp., 600 r.p.m.; jet-pump, 50 hp., 1200 r.p.m.; screen drive, 100 hp., 580 r.p.m.; and stacker drive, 60 hp., 695 revolutions per minute.

Power is brought aboard the dredge by means of 750 ft of one 0 three-conductor stranded armoured cable, and is transformed by means of three 200-kw. with 4000 volts primary secondary. The boat cost approximately $450,000.

COMMERCIAL PARAGRAPHS

Root & Norton have opened a chemical laboratory and assay-office at Durango, Colorado, but will continue the operation of their office at Silverton.

Into Catalogue No. 35, vest-pocket size of 94 pages, the **A. Leschen & Sons Rope Co.** of St. Louis has condensed a great deal of useful data on ropes and accesories. Engineers at mines and works should secure a copy of this.

The April number of 'The Yellow Strand', a monthly of the **Broderick & Bascom Rope Co.** of St. Louis, contains interesting notes on the use of cables in tying log-rafts, in quarries, in logging, and a simple device for lubricating wire ropes.

In a recent leaflet, the **West Coast Gas Engine Co.** of San Diego, represented at Los Angeles by Collins & Webb, gives some details of its engines, especially mining and prospector's hoists. Collins & Webb are also agents for the Mansfield Engineering Co., of Indianapolis, makers of excavating machinery.

EDITORIAL

OIL development proceeds apace, particularly in Texas. There is need for this liquid mineral. A statement issued by the Department of Commerce shows that 682,226 barrels of oil were supplied during February to vessels engaged in foreign trade, as compared with 387,965 barrels similarly consumed in February 1918. For the eight months ending with February 1919 a total of 4,902,060 barrels was used thus, as against 3,787,690 barrels in the corresponding period of the previous year. The consumption in February is equivalent to 165,000 tons of bunker-coal.

EXPORTATION of gold from Australia is now in the hands of a Gold Producers Association, the mine-owners of the Commonwealth having obtained the Government's permission to sell their own production of the metal for three months as best they see fit, thereby securing a premium on the standard price. The Association deals only in Mint certificates, obtaining the gold from the Treasury as required, the output having been pooled and refined at the three mints, at Sydney, Melbourne, and Perth. The profit is shared pro rata among the producers. If successful, this arrangement will be continued.

THE American Institute of Mining and Metallurgical Engineers will hold its next convention at Chicago, on September 22 and the four following days. This meeting promises to be one of unusual importance, as subjects of vital concern to modern metallurgy will be under discussion. In addition to the technical discussions, an elaborate social program is being arranged and excursions by the Institute as a body are planned to many points of interest in the vicinity, including the steel mills at Gary, the oil-refineries at Whiting, metallurgical plants at East Chicago and North Chicago, and to the LaSalle district, where the cement, coal, and zinc industries are represented.

QUOTATIONS for silver have risen in a way to gladden the miner. For more than a year, that is, since the price was fixed by Anglo-American agreement at about $1 per ounce, the mining community has awaited the time when a free market for the metal would be established by removing the embargo upon export, feeling assured that the removal of the restriction would cause an immediate demand for the metal from other countries, particularly the Orient. On May 5 the United States government lifted the embargo and on May 10 the British government followed suit, the immediate consequence being a rise to $1.05¾ on May 9 and to $1.19¼ on May 12. On May 10 the steamer 'Nanking' took $14,000,000 worth of silver from San Francisco to India.

DISMISSAL of the appeal in the case of Amalgamated Properties of Rhodesia v. Globe & Phoenix Company is recorded by the 'Financial Times'. This suit has been long-drawn, for the first hearing started in October 1915. The cost of the litigation to the defendant is estimated at about a million dollars. Our London contemporary remarks: "It is to be hoped that, either as the result of a reform of the Rhodesian mining law or the self-control of those who hereafter feel themselves aggrieved, the question of extra-lateral rights will never have to be fought out again in the British courts." This will interest our readers because 'the law of the apex' was introduced into Rhodesia by American mining engineers.

THOSE compelled by the necessities of business to travel by rail are not enamored of the Government administration of this important public utility. It is more costly and less comfortable than it used to be, and the traveler has the annoying feeling that he is helpless to protest. Since the Government took hold of the railroads the increase in rates and fares has been $1,100,000,000 per annum, and only a few weeks ago a further $65,000,000 was added to the several increases in wages previously granted, making the average wages of all employees $1460 per annum as compared with $1004 in 1917. We miss the competition that provided redress for poor service. The bureau for complaints and suggestions affords no substitute for the discipline of healthy competition.

ON another page we publish an account of the meeting of the Montana section of the Institute; this was called mainly on account of the fortunate presence, at Butte, of Messrs. James F. Kemp and Charles K. Leith, both of whom delivered the thoughtful and interesting speeches that would be expected of them. Our readers will be glad to read the summary of their remarks as recorded by Mr. Oliver E. Jager, who was kind enough to act as our correspondent. We note, with pleasure, that Mrs. Kemp took part, making a persuasive speech in behalf of the women's work and laying stress on the importance of Americanizing the alien elements in our population. Mrs. Kemp is president of that branch of the Institute's activities known as the Women's Auxiliary, which now has 23 local sections. To Mr. E. B. Young, the secretary of the Montana section, is due the credit for the successful arrangement of this meeting.

AUSTRALIA, like other parts of the world, is going through a post-war crisis. With the exception of the Mount Morgan, Mount Lyell, and Wallaroo & Moonta mines, every copper producer is idle and 30,000 men have been thrown out of employment. The agreement between the Broken Hill mining companies and the British government for the marketing of lead is about to end, and anxiety exists as to the future disposal of this metal also. The arbitration award expires on June 30 and it is feared that the labor-unions will demand impracticable terms, such as 33 hours of work per week and a minimum wage of 16 shillings, as against the present minimum of 12 shillings. Australia is realizing the smallness of its domestic manufacturing industries and the large volume of imports in its trade.

PROHIBITION would not seem to be connected with the mining of copper; at least, nobody has suggested that the men mining that particular metal come especially under the embargo as to intoxicants; but we are informed that prohibition does affect copper mining in a curious way, namely, that there is a great demand for the copper tubing required to make stills. At Houghton it is reported that demand for copper is coming from every part of the country, notably from the States in which prohibition is the law. Two yards of copper tube is required for every kitchen plant used in the manufacture of beer or whiskey, so that each still is counted to use 150 pounds of copper. However, the producer of copper must not become unduly stimulated by this good news, for Uncle Sam has a way of enforcing his laws, among which are included severe penalties for the unlicensed use of stills.

AMONG the opportunities for becoming rich offered to the public we note an advertisement in the 'El Paso Herald' issued by a gentleman whose business address is given as the Paso del Norte hotel. He asks the readers of that newspaper to "take a flier" in Government lands having geologic features inviting the supposition that they are oil-bearing. He states that the land examined by him was made "within the last 1000 years," for it is a pre-Cambrian formation. Evidently his idea of geologic chronology is out of joint. The printer may be responsible for some of the errors in his statement that this Cambrian—he drops the "pre" as insignificant—"zone' is overlaid by the "Carboniferous formation of the jures toras age." Does he mean Jura-Trias? Perhaps he does, but even the typographic blunder does not greatly mar the significance of his information. The Devonian formation, coming next, "is undoubtedly of animal age." It is a queer menagerie, is it not? the delirious trimmings of geology. The limestone contains "fossiteles," monsters of the primeval slime, presumably, and "a great thickness of oysters"; hence the milk in the cocoa-nut.

REMEDIAL action against trade combinations in England has caused the suggestion to be made that syndicated newspaper concerns like the Northcliffe press should be made subject to discipline. With the suggestion comes a reminder of the baleful influence of the Hearst string of papers. Our readers will recall the fact that not long ago, in these columns, we advocated a restriction of newspaper mongers, because the control of a number of papers by any one man gave him, as it gives Northcliffe and Hearst, a power wholly out of proportion to his moral worth or intellectual character. Mr. J. L. Garvin, editor of the 'Observer' and one of the most notable of living journalists, asserts that Lord Northcliffe's personal press campaign against the British Premier, Mr. Lloyd George, "will mean the end of Lord Northcliffe as proprietor of the syndicated newspapers." We hope so. He proceeds to say: "Legislation would be introduced and carried putting an end to multiple proprietorship of the opinion-making powers of the press. It would be declared incompatible with the moral basis of representative government and with the unwarped play of democratic freedom." A true word, well spoken.

DISCUSSION, this week, starts with a letter from Mr. Oliver E. Jager, formerly smelter superintendent at Cerro de Pasco, and now at Butte, Montana, where he is collecting notes for a series of articles to be published by us. He discusses the foreign language question and the mental training obtained by the foreigner that learns to speak English, not without adverting to the failure of so many in our profession to obtain the educative effect of learning the languages of other peoples. Mr. P. A. Robbins, formerly the manager of the Hollinger mine, at Porcupine, returns to the charge and meets sundry criticisms offered lately by our friend Mr. W. DeL. Benedict of New York. Our recent editorial on wild-cat activities has elicited some pertinent remarks from Mr. W. D. Bohm, of Boise, Idaho. He has no particular sympathy for the simpletons that are worked by irresponsible promoters, taking the view that most of them expect to find somebody more gullible than themselves on whom to unload at a profit. Mr. J. H. Devereux, of New York, differs from Mr. Beardsley, who wrote, a month ago, demurring to some of our editorial comment on the flotation litigation. Mr. Devereux writes as a mining engineer keenly aware of the high-handed methods of the Minerals Separation company. It may be mentioned here, incidentally, that we have received copies of the briefs and arguments submitted before the U. S. Supreme Court, last March, in the final hearing of the Butte & Superior case, and we expect to publish excerpts from these records, knowing that they will interest man of our readers.

The Treaty of Peace

Citizens returning homeward on May 7 read their evening papers with faces set sternly, for most of them were reading the terms of the treaty presented that afternoon to the representatives of Germany at Versailles. If they thought the terms severe, they had but to recall the fact that the day was the anniversary of the sinking of the 'Lusitania', whereby 1154 non-combatants, including many women and children, were murdered. In truth, it would be a sloppy sentiment that would regret the severity of the punishment imposed upon the Enemy. Only a man whose memory failed him could feel sorry for the plight of those who broke into Belgium and there ravaged and destroyed life and property for four long years, for those who invaded France and exercised every devilish ingenuity in devastating a country engaged from the first in defending itself against remorseless aggression, for those who aimed by piracy to win command of the seas, for those who claimed that necessity knew no law and the will to power no compunction. They disregarded every covenant that hindered their ambitious purpose; they trampled the Hague convention in the dust and tore the Belgium treaty into scraps of paper; they flouted every rule devised by man for mitigating warfare; they scoffed at chivalry and sneered at sportsmanship; they deemed themselves above all international laws; they made themselves outlaws. Let those who now pity their plight imagine their own country treated as Belgium was; their own homes destroyed by scientific incendiarism, their wives and daughters debauched, their sons carried into slavery, soon to die of mistreatment or to be returned the mere wreckage of manhood; let them think of the beastliness and the horror that were the portion of the innocent people of Belgium and of the misery and sabotage inflicted upon the people of northern France; are their memories so poor that they have forgotten these damning facts already, are they callous to the sufferings of their own friends in order to cherish sympathy for a pitiless enemy, who would have done "so to them and more also," if he had broken the defense of the Allied line. Remember the fallen. Shall we hold the sacrifice of their life and happiness so cheaply as to forget for what they fought, and for what they died? Shall we compromise with the Enemy, whose insane ambition and bloody purpose called them from peaceful toil into a living hell, and from the sunshine of home into the darkness of a foreign grave? Keep faith with the dead! The terms are no more than sufficient to destroy Germany's power to start a military, naval, or economic offensive for a generation at least. We rejoice to think that the defender at the gate of western civilization, France, is assured of protection and will now be able in security to recover her vitality and her happiness. It was a great moment for M. Georges Clemenceau. The only survivor of the French deputies that signed the protest against the seizure of Alsace and Lorraine 48 years ago, he stood before the gathering of delegates from the four corners of the earth and in words of grim significance presented the account to the great marauder. The reference to the "second" treaty of Versailles recalled not the first treaty of that name, a compact signed in 1756 between Louis XV of France and Maria Theresa of Austria, but the meeting in 1871, at the end of the Franco-Prussian war, at which the German kings and princes constituted themselves into the German Empire and crowned William I, the grandfather of the fugitive at Amerongen. The performance of that ceremony in the palace of Louis XIV was a gratuitous insult to the French, but it is now compensated by the acceptance in the same palace by the Germans, no longer represented by kings and princes, but by citizen delegates, of the terms of their humiliating surrender, in the form of a penitential volume containing the numerous conditions deemed necessary to guarantee a durable peace. The German spokesman, Count von Brockdorff-Rantzau, made a haughty reply, but admitted the acceptance of defeat and the necessity of reparation; he acknowledged the wrong done to Belgium and demanded that Germany be admitted into the League of Nations. He did not rise to speak, but kept his seat without apology—as if to remind us of Junker manners. His speech was so truculent as to be considered insulting by some of those present. Retribution has come to the aggressor, but not regret. The German's attempt to win domination caused the loss of millions of lives and suffering that seared mankind, but his main regret is that he failed. The temper of the envoy's reply does not augur well for the performance of the drastic conditions imposed by the treaty or for those yet to be specified in completing the work of reparation, but justice is well prepared. The complete demobilization of the German armies and the surrender of her fleet, the demolition of all military defences within a zone 50 kilometres east of the Rhine, together with other precautions on the part of the Allies as specified in the Treaty, will render bad faith impotent if it should prompt an attempt to evade the conditions prescribed. The punishment befits the colossal crime of which an outraged civilization has found Germany guilty. What a contrast between this day and a year ago! If any man be tempted to be tender-hearted to the pitiful culprit, to the fighter that would not stay for the count, to the swashbuckler that yelled 'kamerad' as soon as he saw the fight was going against him, let him imagine what terms a victorious Germany would have imposed on Belgium, France, England, the United States, nay, upon the neutral countries also, because they had refused to play her game. Nor is much imagination needed, for do not the so-called treaties of Brest-Litovsk and Bucharest indicate what the vanquished were to expect? Remembering them, the treaty of Paris seems moderate in its exactions. But what terms of pacification could be so humiliating as the acts of the Germans themselves? Any man may be wrong, any man may be beaten in a fight, and yet preserve his self-respect; but to cease fighting at the first sign of defeat is contrary to all ideas of sport. The Germans sneer at our Anglo-Celtic notions of sport, of playing the game, and of taking a licking, if need be, manfully. They are welcome to their code. To us it seems that the climax of the German tragedy was not at Versailles, not on the Marne, neither at Verdun, nor the Argonne, but at Scapa Flow in the Orkney islands, when the German grand fleet came under its own steam to surrender to an enemy it had refused to fight. They planned to win the sovereignty of the seas, they built a splendid navy, they looked to the day of victory, they toasted *Der Tag*—and they took their navy under its own steam into prison, there to be scrapped. They might have fought and gone down in imperishable glory, defeated but not disgraced. Think of the Germans ever starting to build a new navy and of talking again about *Der Tag!* Echo would answer *Der Nacht*—from every cave on every coast of the seven seas; derisive laughter would shake the sides of every screaming sea-gull from the North Cape to Patagonia. There is the German defeat, not that her enemies encompassed her at last and brought here to her knees, broken, but that she was a quitter. And these were the people that had a heaven-sent mandate to rule the world! They will bluff and they will whine in order to escape the consequences of their crimes, they will use bolshevism as a blackmailing threat, they will appeal to the humane feelings that they themselves trampled underfoot, but the Peace Conference will stand firm in the consciousness of doing right. The Allies must support the Conference, which has endeavored to reconcile their conflicting interests. If most of them are dissatisfied, on selfish grounds, it only serves to prove the impossibility of pleasing everybody and the probability that where nobody is wholly satisfied, everybody's interest has been fairly considered. The Treaty of Peace is a sincere effort to adjust a vast disagreement equitably and justly.

Labor and the Treaty

Nine claims proposed by the Commission on International Labor Legislation for insertion in the treaty of peace, were adopted by the Peace Conference in plenary session at Paris on April 28. The effect of including this statement of economic principles in the Treaty will prove far-reaching, for it is stipulated that (1) labor shall no longer be regarded as an article of commerce, (2) the employee and the employer alike shall have the right of association or combination, (3) a rate of wages adequate to maintain a reasonable standard of living shall be established, together with (4) a standard eight-hour day, and (5) a weekly day of rest, (6) the abolition of child labor is stipulated, also (7) equality of payment to men and women performing work of equal value, and (8) a system of State inspection in which women shall participate. No fair-minded man will be inclined to regret the recognition of any of these principles, but it is to be hoped that they will be put into practice with equal fairness. A standard eight-hour day pre-supposes eight hours of honest labor; likewise a rate of wages enabling the workman to live decently carries with it the obligation to perform his share of the contract honorably. Agreements, contracts, and statements of high principles are of little use unless they are accepted as binding on both sides. We do not say that organized capital, in the form of companies, has not tried to evade its obligations here and there, but usually the possession of tangible property gives opportunity for legal punishment for such breaches of faith, whereas organized labor, in the form of unions, has too frequently welched, relying upon escape from legal punishment through the lack of possessions or of persistent identity. For example, the copper miners have accepted the sliding scale based upon the price of the metal and have been pleased to accept the bonus due to them monthly on account of the rise in copper quotations, but, as soon as the market relapsed and the sliding scale turned against them, they have not hesitated, in places, to revoke, without penalty. It is a poor rule that will not work both ways, and it is a futile agreement that is concocted for the benefit of one party. We hope—and the wish, of course, is father to the thought—as fair concessions are made, grudgingly by some, unselfishly by others, to the laboring men, that they will rise to the opportunity of making these concessions of the maximum value by living up to the spirit of them, so that they may be maintained in beneficent existence. It must be recognized that labor and capital are mutually dependent; only when employed intelligently together do they become valuable. The rate of wages will not create a comfortable way of life unless the cost of living is kept down, and that is impossible if labor is inefficient. In the last resort, it is the efficiency of labor that regulates the cost of production; but we do recognize the burden imposed by the middle-man and realize the growth of that parasite on the social economy. The distribution and marketing of staple commodities is done in an unnecessarily expensive manner even in a highly developed social organism such as ours. Most of us learned that by personal experience during the War. A higher standard of living is dependent not only upon wages but upon a higher standard of thinking, which is the product of education. Happiness does not come from idleness, although we can forgive the workmen for believing it, having regard to the example set by many of their employers. Neither rich nor poor, neither plutocrat nor proletariat, finds happiness in doing nothing; yet both alike make the pathetic blunder of thinking that happiness can be found in dissipation, a fallacy that is usually punctured by a funeral. It is noteworthy that the points scored by the Commission on International Labor appear to omit reference to the housing of laborers, to providing them with homes, without which no decent or self-respecting conditions of living can be maintained. We shall not be sorry if the Treaty of Peace includes stipulations helpful to the stabilizing of industrial conditions and the removing of grievances, and we hope that such inclusion of them will promote a more reasonable attitude on the part of the two elements necessary to economic prosperity.

DISCUSSION

English and Foreign Languages in Our Schools

The Editor:

Sir—In Mr. W. F. Staunton's excellent letter published in your issue of April 12, emphasis is placed on the necessity of an education designed to give a person the power to think rationally and logically, as distinguished from the German idea of 'training'. The German was 'trained', not 'educated'. Mr. Staunton says, "The English language should be first, of course, *for those ignorant of it.*" The italics are mine, but I wish to emphasize the phrase. At first glance it might seem to refer to newly-arrived immigrants, but let me enlarge its meaning to include all the rest of us. How many of us really know our own language? Why do we enjoy a speech by a university dean, or a sermon by a noted divine, or a classic play? Is it entirely because of the sentiments expressed? Not altogether. Notice the comments made afterward by the hearers, and you will find in nearly every case a tribute to the beautiful language used. That means that the speaker knows English. It is safe to say that our knowledge of the language is not what it should be. I would not say that our entire educational system is wrong, or that no attempt is made to teach our mother-tongue; but I do say that the system needs to be watched and improved, and that more importance should be attached to English in our schools. Look at the average newspaper; while some papers make praiseworthy efforts to maintain a high standard, it is not hard to find instances of the careless application of the rules of grammar and syntax. The plethora of magazines with which we are inundated month by month seems to indicate a desire for quantity production rather than for quality. Some of these publications apparently prefer a story to be liberally embellished with slang. Consider the average letter you receive—excepting purely business letters, which are a thing apart—and analyze the composition, the phraseology, and even the spelling of it. You will see room for improvement and [illegible] bulary needs enlarging. We are also too [illegible] r daily speech. It is getting to a point [illegible] guage is considered merely as a vehicle for [illegible] g ideas, regardless of the forms used. It [illegible] to note that most of our important mining [illegible] ow giving more attention to English in the [illegible] courses, so that the gradute may be an edu[illegible] not a mere technician.

[illegible] us consider the question of the foreign [illegible] n the school curriculum. This point has received considerable attention lately, owing to debates in some State legislatures, and elsewhere, as to the complete elimination of German in schools and colleges. This subject may be considered under three headings: (1) educational; (2) commercial; (3) patriotic or national.

The mental training acquired by the study of a foreign language is very great; and, further, it is not until you commence the study of a foreign language that you realize how little you know about your own. Translation does not consist in the mere ability to substitute the words of one language for those of another. There is a feeling—a spirit—that can only be properly caught when one has acquired the art of *thinking* in language other than his own. The enlarged horizon that comes from knowing another language is something worth striving for, and must be experienced in order to be appreciated. It opens up a new world to its possessor. The foreigner will tell you that the average American, unlike the European, does not learn a foreign language easily. One reason for this is our isolated position. Another is the narrow viewpoint of those who maintain that "English is good enough for me." This attitude is to be deprecated, as it tends to prevent a proper appreciation of other peoples. It is impossible to get close to a man when you talk to him only through an interpreter, as the personal element is missing. The real viewpoint, the real spirit, the active tendencies, and the true thoughts of a people can only be acquired by knowing their language. It may be urged against this that translation of books and newspaper articles are easily obtainable, but when one compares the large amount of publication with the small amount of translation, this argument fails. During the first two years of the War we had access to several German weekly papers, the perusal of which was instructive for this reason: it showed the kind of misinformation that was being served up to the German people. It was appalling to think that a supposedly intelligent people should be so systematically deceived, but it made clear many things that would otherwise have remained obscure, and we obtained first-hand information on what the German was thinking about. Was not such a thing worth while? Of course, I do not pretend to say that everyone should learn Spanish, in particular, or French or Italian, but I maintain that the study of some living foreign language is an important part of a good education. It is not necessary for everyone to learn German, but that is quite different from saying that nobody shall learn it, which is what its banishment from the schools practically amounts to. Another thing worth remembering is that to have studied any foreign language is of immense benefit in the study of some other foreign language, no matter how dissimilar the two may be, as one learns, in the first case, to think in some other man's way. That is to say, having studied French would make it easier to learn Norwegian than if no foreign tongue had ever been attempted.

Coming now to the commercial aspect of the case, it is almost needless to enlarge on the fact that one cannot do business with a man with whom it is impossible to converse. What chance has modern salesmanship by the medium of an interpreter? I have in mind, especially, South American trade, having heard a lot lately about capturing this trade. Some of the attempts to do this which I have witnessed were ludicrous in the extreme. One of the principal reasons why the German was getting so much of the Spanish-American trade was that the German is a born linguist. He gets close up to his prospective buyer by talking to him in his own language—at the same time handing him a catalogue printed in Spanish. To expect men who speak no Spanish to secure orders in South America is foolish on the face of it, but I have met many commercial travelers there who were trying to do it. When one considers that, with the exception of Brazil and the Guianas, the Spanish language covers the vast territory lying between the Rio Grande and Cape Horn, it must be admitted that Spanish has a commercial value. Within recent months there has been some discussion in the correspondence columns of the 'Engineering & Mining Journal' on Spanish for the mining man. The case for the 'Spanish-not-essential' side of the question seems very weak. A good knowledge of Spanish is necessary for the mining or metallurgical operator in Spanish countries. Inefficiency and accidents result from an inability to explain things properly to the native workmen, while the finer points of influencing officialdom—which has to be done quite often—are impossible without considerable fluency. The other languages of interest to mining men are German and French, on account of the technical and scientific publications, which are not often translated.

Under the patriotic heading I would enter a protest against the entire banishment of the German language. Let it be clearly understood that I am not advocating German for its own sake, but because the lack of knowledge of this tongue would give the German an advantage. No one will dispute the fact that the War has shown us that, even after the peace treaty is signed and sealed, the German will still need watching. How are we going to watch the German in our midst if he can talk without our understanding him? How are we to keep in touch with what the German in Germany is thinking about, if we cannot read his books and newspapers? It has been argued that the teaching of German in our schools gives an opportunity to a teacher of pro-German tendencies to instill into the youthful mind the pernicious ideas of militarism, or what not, by using certain books as school-readers. My answer to this is that there is something radically wrong with our school-boards if anything but good Americanism is allowed to get into the teaching. The idea of getting rid of everything that savors of Germany is all right, but, like all reforms, it is liable to go too far by eliminating something we could use to our own advantage.

After the excitement of the war and the peace has cooled down, and we again become capable of making calm decisions, let us hope that the question of languages, both English and foreign, will receive its proper consideration at the hands of our educators and legislators. At the same time let us retain a little good, honest hate, "lest we forget."

OLIVER E. JAGER.

Butte, Montana, April 27.

The Status of Gold

The Editor:

Sir—In the issue of March 22 appeared a letter from me on this subject, comparing the relative values of British consols and gold in the years 1812 and 1918. My figures were based upon an assumed present value of £80 for a consol of £100 denomination. You corrected this valuation to £59, but unfortunately did not extend the correction throughout the article. The corrected conclusions should have read:

"In 1812 one hundred sovereigns in gold were worth the future labor pledged in a consol bearing the inscription £100. In 1918, sixty sovereigns are worth the future labor pledged in a consol bearing the inscription £100. In other words, the investment value of an ounce of gold in 1918 was 50% greater than in 1812. Gold has enhanced 50% in its labor equivalent. . . . Therefore, for the purposes of hoarding, gold has an enhanced value over government securities, for today a man with 61 sovereigns will hoard them rather than hoard a British consol of £100 denomination."

In regard to the criticism by Mr. Benedict in your issue of April 26, I do not find much which calls for reply, for my argument is dismissed by the suggestion that I "do not seem to comprehend the basic principles of money, because I have not studied political economy sufficiently," and in his concluding paragraph my critic offers the use of 800 books upon the subject of economics. While admittedly the professional proof-reader has covered more ground than I, yet within the limits of my understanding, that which I have read, particularly in regard to money, has been digested and absorbed. Between the lines of Mr. Benedict's concluding paragraph, I read, "Shoemaker stick to thy last:" Ill-timed advice, else were Germany and Poland without their presidents, and the world without its food administrator. Has Mr. Benedict been so deeply immersed in his library of 800 books that he has failed to mark the present tendency to insist that the shoemaker shall lay aside his last—for a portion of each day at least? Adage and proverb for the unthinking past; today even a mining engineer must think beyond the confines of his profession if he would perform his full share of the world's work.

No proof is presented by Mr. Benedict that the financial world reached finality in its conceptions of 1812; indeed, did not the same masters of destiny who ascribed its weight to the gold sovereign also fix the boundaries of European countries so as to preserve peace? Mr. Benedict is not quite clear in his argument that it is not the Government stamp which fixes the value of the coin. The weight and fineness of the coin are fixed by statute, and the Government stamp upon the coin guarantees the legal weight and fineness at the time of minting. When we buy drill-steel we choose a brand known to possess the qualities that particular brand guarantees. But the manufacturer does not guarantee the brand against short weight in retail trade, nor against substitution of inferior steel by unscrupulous dealers, nor does the brand fix the price. Milk is bought by the quart, and by a system of inspections the Government tries to protect consumers against fraudulent measures, but the inspection stamp upon a measure or weight does not guarantee that these will not be tampered with after inspection. The coin is not redeemable; it is the final commodity in commercial settlements. The quantity of gold in a coin is fixed by statute in order that the receiver may know just what weight of gold he is entitled to receive. It is the statute and not the embossing stamp which fixes the "status of gold."

I cannot feel that Mr. Benedict and his array of 800 books, fortified by cigars and refreshments, would alter my opinions unless coupled with confuting evidence.

I have had some such experiences as he proposes, two of which produced the most valid reasons for protesting against an alteration in the weight of coins. One friend, a gold medallist in political economy at a leading university, whose youthful knowledge had been increased by 25 years of legal practice, finally concluded a series of discussions (with cigars and refreshments) by exclaiming, "I have it, your plan means repudiation, repudiation of debts, an impossible step for any stable government to take;" to which I could only reply, "Repudiation, yes; but so is increased taxation repudiation; in order to pay for the War, we must repudiate the incomes and heritages which we have guaranteed to individuals."

Another friend, financial editor of a leading Canadian daily paper, voiced the opinion (after cigars and refreshments) "your talk sounds all right, but the plan is not workable, one reason being the great quantity of paper, commercial as well as governmental, which is redeemable in gold at its present value." A practical but not an insuperable objection.

I have not read Mr. Benedict's article upon 'What is a Dollar', and I presume that Mr. Benedict has not read some previous notes of my own, hence probably neither of us is conversant with the extreme depth of erudition of the other, but I grant, without discussion, that in those 800 books he marshals a crushing weight of argument. Referring to the article of Mr. McPherson, not, however, dismissing Mr. Benedict's criticism, but coupling the two together, there are some points to be considered.

In British consols, I find Mr. McPherson's 'twin-coin' idea exemplified. Great Britain issued her gold sovereigns of a legal weight and fineness, and then, doing exactly what Mr. McPherson suggests, she printed £100 on pieces of paper and issued these as running mates for the gold coins. Neither the gold coins nor the pieces of paper are redeemable; they are both money, the only difference being that the consol bears interest. Mr. McPherson says it can't be done, but the fact remains that Great Britain did it, and did it successfully on a large scale.

Mr. McPherson says "yet he (Mr. Van Dyke) would laugh in reasonable merriment at a Mexican leader or a Bolshevist ruler who should order the printing-presses to start as the nation was running short of money, to pay foreign debts, or any debts."

Yet during the past four years the printing-presses of France, Italy, Great Britain, Canada, and, in fact, all the Powers, have been doing this very thing, and if Mr. Van Dyke's figures are correct, from a total pre-War indebtedness of 28 billions a printing-press credit of 280 billions has been created by the belligerents.

Mr. McPherson says further: "If any nation or group of nations can double the figure on the face of a gold coin . . . that nation can as easily treble it or . . . multiply it by tens or hundreds. There is, however, one obstacle always in the way of this, and that is the intrinsic and social value of the metal itself." Just what is meant by "the intrinsic and social value" is not clear, but the facts are that there is no obstacle in the way of any nation doubling the figure upon the face of a gold coin. Possibly Mr. McPherson is not aware that Argentina had, long ago, done this; that it has provided a flexible internal credit and that no disaster has followed the innovation. It is only in international exchange that Argentina recognizes the international value of gold; internally gold has double the international value.

If by "intrinsic" value is meant the value in open markets, then it should be noted that in the Orient gold has for some time been selling at from 25 to 30% premium. If by "social value" is meant local selling-value, in the arts and trades, it is interesting to note that the value in London and Paris has been at a high premium, from 25 to 30%.

The statement "gold is called into active functioning as a monetary metal during war times" may be true in the time of small wars on account of increased commercial activity, but it has not been true during the present war. The balance of trade has been so overwhelmingly against Europe and Canada in reference to United States that gold ceased to perform its regulating functions. The statement "if gold coin itself were arbitrarily stamped with figures far above its intrinsic value it would not possess complete security as a means of value" is seemingly based upon the common misconception that gold has a standard intrinsic value. Gold has an arbitrary monetary value, but an intrinsic value is a matter of locality and existing conditions in that locality.

I have already pointed out that within Argentina the purchasing power is doubled, and in my letter which appeared in your issue of March 22 I pointed out that under the conditions existing in England in 1812 gold was accepted at a less value than it is accepted at today under existing conditions. The adoption of gold as a standard of exchange did not give to it its value as an article of exchange any more than did the adoption by the medical profession of quinine as a drug give to that drug its medicinal value. Gold was adopted because it possessed facility of exchange, and quinine was adopted because it possessed medicinal value.

The fundamental human regard for gold seems to be atavistic, regardless of any decree of governments. All that governments can do is to standardize and stabilize the relationship between gold and the mass of other wealth. Great Britain tried to do this and her effort seemed successful, but time has shown a gradually accumulating error, and the present value of consols indicates that a considerable adjustment is necessary in the status of gold.

Manifestly, there is no hope of paying the balances of war-indebtedness by exchanges of gold, but ordinary trade-balances will have to be settled by the exchange of some commodity that is internationally acceptable. Previous to the War the exchange of gold was somewhere in the vicinity of 1% of the total trade, but what it will be in the future we cannot say; all we know is that the creditor nations will have to accept a balance of trade against themselves, otherwise the debtors will not be able to liquidate their indebtedness, and it is only reasonable to expect that the demand for gold for exchange purposes will be greater than before the War. As there is only a definite amount of gold in the world, either some substitute for gold will be necessary, or it would seem necessary to ascribe a greater exchange-value to an ounce of gold.

The dominating commercial position of Great Britain before the War was due to her gold resources; her gold was to a large extent placed with foreign and local institutions, subject to call, and it was her ability to call in gold from any part of the world that enabled her to regulate exchanges in her favor and thus maintain her position as the clearing-house of the world. Before the Franco-Prussian war, Paris shared with London a large part of the exchange business of the world, but after the war the gold resources of France were required to successfully maintain the value of the franc, and she gradually lost her profitable business of discounting foreign bills.

Differences in trade-balances might be (and during the War have been) settled by an exchange of securities. But securities are subject to 'bull' and 'bear' manipulation. Inside information that a government proposed to use securities as a means of settling its debt would inevitably lead to speculation in those securities, a fact which makes such exchanges dangerous to business done upon a small margin of profit. Hence gold, with an ascribed value, forms a stable exchange commodity, subject usually to only a small fractional variation due to difference in insurance and express charges, and fractional premiums caused by local shortages in reserve stocks.

Government stocks are the resting places of the bulk of the world's supply of gold, and by arrangement with domestic financial institutions the foreign credits of a country are bolstered up by the Government. If each Government possessed a surplus of gold over any demands likely to be made in the support of its commercial credits, then there would be little need of altering the ascribed monetary value of gold. There is, however, grave danger of a shortage of the commodity owing to the huge trade-balances that will have to be settled in the future, and to the enormous payments of interest on war bonds.

Financial institutions are becoming largely internationalized and a shortage of gold in the world's business would tend to form closer financial alliances for the purpose of manipulating exchanges. The result of such manipulation would, if not counteracted, cause a reduction in the costs of production of raw and manufactured commodities; it would react to re-establish British consols, and enhance the values of high interest-bearing war-bonds.

Reductions in costs could only be brought about by increased output of workmen or reduction of wages. There is small possibility that organized labor, backed by a newly created sympathetic public sentiment, will permit conditions to revert to pre-war standards, and if anything like present standards of output and wages are maintained then the need will increase for a revision of the status of gold.

If an actually higher value were to be ascribed to gold, the entire stock of metal would naturally be commandeered by the various governments and re-issued, all profits in the transaction accruing to the governments; if, however, the adjustment be made by reducing the costs of commodities and thus giving a relatively higher value to gold, then the profits would accrue largely to the holders of securities. In opposition to a reduction in the cost of commodities there is the proposal of international labor agreements, with limited hours, minimum wages, exclusion of child labor and other reforms. A strong public sentiment has grown in favor of these, and it is doubtful if labor will consent to speed up in the future as in the past, and it is quite certain that wages will not return to pre-war standards either in Europe or upon this continent. It, therefore, seems probable that sooner or later the status of gold will of necessity be adjusted.

The easier method of making the adjustment is to adjust the valuation of an ounce of gold. The benefits of such an action will be distributed to the entire population of the civilized world. If the adjustment be made by reducing the costs of commodities then the profit in the adjustment will accrue to the relatively small class of bond-holders. This will only aggravate the conditions that exist today by widening the gulf between those who have a surplus and those who have none.

The payment of war debts can only be made in the products of future labor or by the exchange of such tokens of labor as gold, silver, and platinum, of which accumulated stocks exist in the world. It will, therefore, be understood that the payment of war debts merely means a re-adjustment of the wealth held by individuals.

The securities that cover the war debts are held by certain individuals. Other individuals must produce commodities with which to redeem those securities, and as the security-holders receive their incomes, portions of the incomes will be taken away from them to apply in reducing the war debts. Thus we have a recurrent cycle of operations which will eventually reduce the average of individual fortunes until the war debts are extinguished and the process will be long or short, depending upon how drastic taxation becomes.

The whole world is not going to speed up and produce more commodities than are required, thus piling up unused stocks and proclaiming the debts paid. Production is going to meet demands and only from a profitable exchange of commodities can the debts be extinguished. The only exception to this is in stocks of precious metals, which can be stored for use by future generations. The building of public utilities as a charge against future generations will not be above normal unless heavier taxation be resorted to. It seems to me that the maintenance of gold at its present value is going to increase the gravity of the present financial situation. The raising of gold to a higher valuation would ease present conditions and stimulate production of precious metals.

Increased production of precious metals would mean a certain storage of unused commodities which could be paid for by future generations. This phase of the subject is so complex that I have made no attempt to analyze it in the short space of this letter, but if what I have written causes thought upon the subject, I feel that others will at least see a reasonable argument in favor of recoining gold coins at one-half or two-thirds of their present weight.

P. A. Robbins.

San Francisco, May 1.

Who Will Hold the Sack?

The Editor:

Sir—That pertinent editorial in your issue of April 26 revives a perennial question. In my long experience, covering most of the known mining regions, I have found—whether it be in the U. S. A., Australasia, Africa, or anywhere, that the majority of the public—of whom somebody remarked something about 90 odd per cent fools—will persist in regarding mining as a "game" and a mighty low-down one at that.

I think, therefore, that we ought not to regard the promotion question too seriously, but take a more Gilbertian view of it. Let us, for instance, endeavor to permit "the punishment fit the crime"—and the criminal—and, instead of hounding the average promoter, arrange something pleasant "with boiling oil in it" for the rascals—expecting something for nothing, or hoping to 'pass the buck'—who buy wild-cat stuff.

Repeatedly have I been assured, in many instances undoubtedly in good faith, by broker-promoters that they heartily wished that the public would join them in the development of meritorious prospects on their face-value on equitable terms for all, but that attempts along such lines had always failed to meet with any response, while the highly spiced rubbish was quickly absorbed.

From the innumerable examinations that I have made for clients who 'groused' at being hooked by sharks, and who afterward had to admit that they really had hooked themselves in their craze for getting the edge on some other fellow, I am led to at least suspect that the responsibility rests about 50-50 with the promoter and the dear public.

When the public can be induced—if it ever can be—to realize that opening up mines is almost as risky as opening a new grocery store, it may take a tumble, and incur the risk intelligently and economically. The final analysis, to my mind, places the greatest onus on those looking for 'sure things', of which it must be said, in common honesty to all nature, that there can be no such animal. Hoping for the day when we can again mine like men, taking our chances open-eyed, and unafraid in legitimate development, I am

Flotation Patents

The Editor:

Sir—I cannot agree with Mr. Beardsley's conclusion, as stated in your issue of April 12. The Courts not only are required to act solely upon the record before them, as he states, but also the litigants are bound by their own testimony. Did not the Minerals Separation company claim that until it reduced the oil to a "critical point" it failed to get the separation? Did it not claim as its invention the ability to get with a small percentage of oil a result that it could not get with a larger percentage? Did it not state in court that with a larger quantity of oil the process would not work? If so, then the Butte & Superior has also made a discovery. The fact that it is trying to avoid the Minerals Separation patent and the claim that an increased quantity of oil is unnecessary cut no ice.

In 1893 to avoid the Edison Incandescent patents, the Westinghouse Lamp company used a lamp with a cemented plug. It was admitted, indeed it was advertised, that the object was to avoid a detailed specification of the Edison patent. If the Minerals Separation company tied itself to half of 1% of oil, it releases everyone using more, even if it is used for the purpose of avoiding a patent. If a patentee specifies a hexagonal nut as essential, he cannot prohibit another from using a square nut.

As I see it, the Minerals Separation claim is, "You can get drunk on two drinks but you cannot on twenty." Then if a man takes twenty drinks, they cannot charge him with being drunk.

J. H. Devereux.

New York, April 25.

Mine Development in China

By GILMOUR E. BROWN

China is a vast and comparatively unknown country, but it does not follow, as is apparently assumed by many non-technical writers, that its mineral resources are also vast and entirely unknown.

It is scarcely possible to form a reliable estimate of its mineral wealth from one's own comparatively insignificant travels, supplemented by a perusal of the somewhat scanty and unreliable literature available, but conversations with engineers who have visited other provinces has led me to agree with them that the mineral deposits of China are more disappointing than otherwise. It is generally conceded, however, that the coal resources of China are of the first magnitude.

During a prospecting trip undertaken several years ago along the China-Burma frontier I was impressed with the history of the conflicts between the Chinese and the Shans of Northern Burma for the possession of the huge silver-lead-zinc orebody now known to the world as the Bawdwin mines, the property of the Burma Corporation, the silver ultimately finding its way to Peking. That did not tend to corroborate the tales of the great undeveloped mineral wealth of China, and the impression formed then has gained in strength through subsequent travels in several provinces.

The areas most richly mineralized are, as a general rule, closed to the newcomer, either by previous agreements with foreigners or by being in the sphere of influence of a particular nation, or by being situated in a province such as Hunan, where the co-operation of foreigners is not desired; in fact, many American engineers attracted to China during recent years have thrown up their hands in disgust and taken an early opportunity of departing for more enticing lands. I could name a dozen prominent American mining engineers and geologists who have come and gone during the past three years without accomplishing a single stroke of business.

A good example of the locking up of the mineral wealth of the country is that of the Pritchard-Morgan agreement covering an area, 60,000 square miles greater than France, of what appears to be the most richly mineralized province of China and in which although the agreement dates from 1899 no mine has yet been developed under the terms of the agreement. Yunnan, perhaps the next best province from the mineral standpoint, is a French sphere of influence, while the Japanese stranglehold on Manchuria makes the American or European hesitate before venturing capital in that part of the country.

An engineer unacquainted with the history of the existing concessions is likely to pay for his lack of knowledge if he ventures into the arena. One example will suffice: An American concern in the early years of the War secured a contract to build from 1500 to 2000 miles of railway, which was hailed in America as a great success for American enterprise. After surveying parties had been formed and dispatched, no fewer than four nations protested, alleging infringement of spheres of influence, previous agreements, and the like, so that the contractors were left with only one route, which is at present in abeyance, nearly all the engineers having returned to the States.

The acquisition of mining rights over a particular area is so often a political matter that the engineer may be amazed at the results of what in another country would be a simple mining transaction attracting little or no attention. Formerly concessions were granted outright to foreigners, but that is no longer possible except by special agreement with the provincial authorities and the consent of the national parliament. A recent example of such special legislation was the agreement with the Standard Oil Co. for the exploitation of the oil resources of several provinces, from which, however, no benefit accrued to the company.

If foreigners desire to engage in mining they can do so by forming joint companies with the Chinese, 50% of the shares being held by Chinese. That is not usually acceptable to the foreign speculator. The liability of the shareholders in these Sino-foreign companies, as they are called, has not yet been clearly defined.

The present mining laws leave much to be desired. A perusal of a translation of the principal laws failed to reveal any reference to hydraulicking or dredging, forms of mining that are still unpractised in China. These laws have not received recognition by the Diplomatic Body of Peking, and most engineers would feel inclined to ask what the Diplomatic Body has to do with the application of the mining laws. In the non-recognition of the laws by the Diplomatic Body lies a pitfall for the unwary. A case with which I am thoroughly acquainted will illustrate this point.

A company with a foreign interest of —— nationality acquired by purchase a small coal concession from a company with a foreign interest of —— nationality, adjoining a concession of another company with a foreign interest of the same nationality as the newcomers. Work was commenced on the property and preparations made for shaft-sinking, the new-comers having received the verbal permission of the engineers of the Bureau of Mines to commence work while the transfer papers were passing through the necessary departments.

The already established company with the foreign interest of —— nationality approached its legation and urged the legation to prevent the advent of the new-comer on the grounds that damage would result to its property through its presence in the same valley, and besides it had rented the surface rights of the land acquired by the new comers and under the old mining laws it was owner of the mining rights thereof. No notice was taken by the legation that the objecting company had received an extension of its area under the new mining laws and had paid its mine taxes under these laws, and had also neglected to pay the rents of the land it had rented since the new laws had come into force. The legation forthwith proceeded to demand that the officials of the Bureau of Mines stop the operations of the new-comers and eject them from the valley under the terms of the old laws. The new-comers were told by its legation that if they shouldered the debts of the objecting company, and amalgamated with it, the legation's opposition would be withdrawn.

The Chinese officials of the Bureau of Mines were entirely in favor of the new-comers and resented the demands of the —— legation, but as that legation was very powerful they dared not disregard its opposition. Then the legation of —— nationality, representing the vendor interest, appeared on the scene and its support was sufficient to give courage to the Chinese officials, although it was not sufficiently strong to effect a settlement. Finally, when all were tired, the Bureau of Mines appointed a commission to inquire into the dispute under the direction of the foreign advisor to the Bureau of Mines, the finding being entirely in favor of the new comers. An opportunity was given to the legation of nationality to climb down gracefully (at the expense of the new-comers) and the transfer papers were issued 20 months after the new comers had commenced development operations.

The foregoing is a typical example of what one may expect under existing conditions in China and enables one to appreciate the humor of the definition of a diplomat as "one who lies abroad for the benefit of his country".

With his concession papers in order the engineer may think his troubles are over but, he is soon to be disillusioned. All over China the mineral deposits have been burrowed at their outcrops, the burrows being mostly close to the stream-beds, as affording the shortest distance to the deposit. When one burrow is flooded another is started, but in north China most of them are flooded during the heavy downpours of the wet season. When the burrows cannot be unwatered by hand-labor at the height of the dry season, they are abandoned altogether and constitute a menace to future operations. Ample pumping capacity has to be installed to drain them annually, by any foreign-controlled company operating below the outcrops.

These small mines are worked under permits from the local magistrate only; they necessitate constant watchfulness and an expensive organization in the capital of the province to prevent them re-starting work within the boundaries of the concession, for they know full-well that the foreign-controlled concern is going to install pumps and leave these old workings high and dry. It is of little use appealing to the local magistrate, for the ways of the Chinese official are numerous and all equally tedious. It is usual to put him on the pay-roll and avoid trouble.

Mining taxes are not heavy, but the engineer would not object to paying double the taxes if he was relieved thereby of the incubus of defending his concession against the holders of local permits. The Japanese Minister at Peking backed his nationals in 'mailed fist' style in a case against the holders of local permits, so that now the Government officials pay a little more heed to the protests of the people who pay taxes to them.

There is this to be said for the administration of the mining laws, that as long as the operations at the mines are conducted with reasonable care there is practically no interference with the management of the mine. There are none of those inquiries into fatal accidents which are a nuisance in more civilized countries.

PART OF CHINA

A great drawback at the commencement of operations is the time necessary to secure a permit for the purchase of explosives. This usually takes four months, the application having to pass through four departments, while the permit has to pass through the same departments in the reverse order. The permit names the place at which the explosives can be purchased and if it is desired to purchase explosives at another place it takes four months to effect the necessary alteration.

During the first years of the War I held a permit for the purchase of explosives at the nearest port, where, at that time, there were no explosives or any prospect of a shipment from abroad. As the need was pressing, inquiries were made and a quantity owned by a Government railway, was found at an inland town. A request to hold the explosive for four months, until the permit could be changed, was acceded to, but, by the time the permit was altered, a clean sweep had been made of the directorate of the railway, and the explosive was no longer for sale. Another four months were consumed in having the permit re-altered and in answering the questions necessitated by the double change.

It took nearly half an hour on one occasion to convince a customs official that 20 cases of dynamite was a reasonable quantity for a mine to possess.

The railway companies are in a chronic state of shortage of cars due partly to the War but mostly to the wants of the military party in the campaign against the South. Railway cars are not only held up for weeks but several covered cars have been fitted with furniture as residences for officers. There is much to be said for such a dwelling when it is desired to make a speedy departure from the scene of military operations. The foreign-controlled concerns are the first to suffer in the matter of such shortage, which seriously affects the output of the coal mines.

The Chinese coolie is a noteworthy laborer, but, as often happens, cheap labor does not imply a low cost of production, the average coal mine in China showing a higher cost per ton than the corresponding mine in the United States. As far as I am aware, although attempts have been made by foreigners to operate metal mines, there is not one profitable metal mine in the hands of foreigners at the present time.

The coolies are docile and industrious but in the Chinese-owned mines his life is short, owing to the terribly unsanitary state of the workings. Coal is often carried out on men's backs for a distance of a mile underground, there being little or no ventilation possible through the one and only inclined shaft.

The coolie does not appreciate the hygienic conditions of the foreign-controlled mine, but he does appreciate a guarantee of a coffin if he dies or is killed in the mine. With the promise of a coffin he is the company's servant until he fills it. *Resquiescat in pace.*

Costs at the Homestake Mine

During 1918 there was treated a total of 1,628,630 tons of ore, yielding $3.633 per ton. The principal items of expense were the following:

Underground work and hoists	$1.52
Stamp-mills and amalgamation	0.31
Re-grinding	0.02
Cyanidation of sand and slime	0.24
General expenses	0.12
Compensation and sociological	0.08
Taxes	0.21

Some of the other large charges were $107,050 for the Ellison shaft coal plant, and $121,894 for the No. 2 Spearfish hydro-electric plant. Labor in the mine cost 77 cents per ton, and explosives 13 cents. Labor in the mills cost 12 cents, and quicksilver nearly 1 cent. Cyanidation of sand cost 15 cents.

Indicators used in acidimetry and alkalimetry are organic, but the direct cause of color change is not fully understood.

Cadmium Production and Its Use in Solders

The critical scarcity of tin in this country during the War, according to C. E. Siebenthal, of the U. S. Geological Survey, led to Government control of its distribution as well as to a campaign for its conservation. One method of saving tin is to substitute cadmium for it in solder. In the last year of the War the Government and certain large companies began experiments with cadmium solders as a means of saving tin. The results were promising, but the demand for tin decreased, and the armistice was signed before cadmium solders became widely used. The first of the belligerent nations to make large use of cadmium as a substitute for tin in solders was Germany, which from the beginning of the War was cut off by the blockade almost entirely from the world sources of tin. Solders containing 10% cadmium were used in Germany early in the War, and some were reported to contain as high as 30% of cadmium and only 2% of tin instead of the customary 40 to 50%.

About 600 tons of cadmium accumulates annually in America as dust and residue, by-products of the lead and zinc industries, and from these by-products about 100 tons of metallic cadmium is recovered. If all the cadmium dust and residue were treated, the output of metallic cadmium would be small in comparison to the 19,000 or 20,000 tons of tin annually used in this country in solder, even if due allowance is made for the fact that 1 lb. of cadmium can replace from 3 to 5 lb. of tin.

The output of metallic cadmium in the United States in 1918 was 127,164 lb., compared with 207,408 lb. in 1917, and the output of cadmium sulphide in 1918 was 51,702 lb. as against 50,169 lb. in 1917. The average value per pound for metal and for sulphide was $1.48 and $1.36 in 1918, against $1.47 and $1.41 in 1917. Exports of cadmium in 1918 were 62,320 lb., of which 30,440 lb. was sent to France and 20,000 lb. to Japan. The market for metallic cadmium was not strong in the first half of 1918, and considerable stocks accumulated. Production was somewhat curtailed before August and almost stopped during the remainder of the year.

Diamond production of the Union of South Africa in 1918 was 2,537,360 carats, valued at £7,114,867. The Cape (Kimberley mostly) contributed 1,418,440, the Transvaal (Premier mine) 896,039, and Orange Free State 222,881 carats. The output in the previous seven years was as follows:

Year	Carats	Value
1917	2,902,117	£7,713,810
1916	2,346,330	5,728,391
1915	103,386	399,810
1914	2,801,017	5,487,194
1913	5,163,547	11,389,807
1912	5,071,882	10,061,489
1911	4,891,999	8,746,724

One carat equals 205.3 milligrams, about 3.2 grains. £1 normally equals $4.85. Many thousands of natives and whites are employed in the mining and treatment of the 'blue' and 'yellow' diamondiferous ground.

The German Metal Octopus—IV

ISSUED BY THE ALIEN PROPERTY CUSTODIAN

Disclosures by Investigations Conducted by Alien Property Custodian

After the passage of the Trading with the Enemy Act in October, 1917, and the subsequent appointment of the Alien Property Custodian, he caused investigations to be made of the American Metal Co., Vogelstein & Co., and Beer, Sondheimer & Co., as a result of which he took over the entire business of Vogelstein & Co. and of Beer, Sondheimer & Co. and 49% of the stock of the American Metal Co. The investigations disclosed the following state of facts:

As to Beer, Sondheimer & Co.—In August, 1915, Benno Elkan and Otto Krohnknecht, who, as pointed out above, were simply the agents of the Frankfort firm of Beer, Sondheimer & Co. and were conducting, in the United States, a branch of the business of the Frankfort firm under the name of Beer, Sondheimer & Co., American Branch, without the knowledge or consent and against the express wish of the Frankfort firm formed a corporation under the laws of the State of New York called Beer, Sondheimer & Co., capitalized at $1,000,000, and transferred to that corporation all of the assets of the capital stock of the new corporation. Correspondence passing between the Frankfort firm and the American attorneys who advised Elkan and Krohnknecht in this situation and did the legal work in organizing the corporation, clearly shows that the corporation was organized and the assets were transferred to it for the express and only purpose of making it impossible for the United States government, in case of a war between the United States and Germany, to exercise its belligerent rights and take control of enemy property in the United States. One of these American lawyers, writing to Beer, Sondheimer & Co., of Frankfort, after the corporation had been organized and the assets transferred, explains the purpose of the organization as follows:

> September 15, 1915.
>
> Gentlemen: I thought it in line with my duty to you, both in my professional capacity and as an interested friend, that I should write you relative to the recent incorporation of the American branch.
>
> Having discussed a similar proposition with you during my recent visit, and knowing your mind upon the subject, I naturally counseled Messrs. Elkan and Krohnknecht to consider the matter with extreme care before any decisive step was taken. Shortly after my arrival the situation here looked very grave, and the diplomatic complications were a source of apprehension to me. From the various opinions that I was able to secure, it was quite clear that the situation was very serious. Having these facts in mind, and also knowing that you were not inclined to favor the incorporation, Mr. Elkan believed that we should take counsel.
>
> The firm of X. Y.,* which is, as you already know, one of our best firms here (being the same firm that rendered an opinion on the question of * * * †), was employed by Mr. Elkan. This firm of X. Y., after mature consideration, both as to law and the known facts of the diplomatic situation, advised without reservation, that it was necessary to incorporate; in these views I fully concurred.
>
> The means of communicating with you were so meagre and the necessity of keeping the facts from our enemies so evident, that we were compelled to act with extreme caution. We sent you as many messages as possible, under the circumstances; but we received no answer to the cables and wireless messages sent you on the subject, yet we delayed taking action until we believed it was hazardous to wait longer, therefore we acted upon our best judgment.
>
> As far as the incorporation is concerned, personally I looked upon it as the only practical means of protecting your interests here, so that your business could be carried on in spite of any difficulties that might arise between the Governments. The idea was executed with the sole and only purpose of guarding your interests, there being no other consideration present in the working out of the idea. Further than this, the whole matter under our laws here is at present in such position, that at any time, either now or after the conclusion of peace, the corporation can be dissolved and the entire business can be put back under the name of the American branch just as it was before the incorporation. In other words, your interests are the same now as they were before except as to form, but the legal status of the property here has been changed. The whole question is one for you to determine, whether you desire to have the business continue under the present company or not.
>
> I might suggest for your guidance that for the present, and until the War is over that the Incorporation stand as it is, because it not only makes a difference in the conduct of the business as a matter of law, but as you must realize, it makes a decided difference in the opinion of Americans. There is no denying the fact that the great preponderance of American sympathy is with the Allies, and this phase of the question you must bear in mind in considering the advisability of taking any immediate step to dissolve the corporation.
>
> I also want you to know that in taking the step there was absolutely nothing that was done that was not thoroughly discussed and agreed upon by Messrs. Elkan and Krohnknecht, and we attorneys. The company is so organized that it is impossible at this time, or at any other time, except with your consent, that any separation of interests could be made. In other words, the whole business is absolutely in your control.
>
> The matter of the indebtedness of the branch to you, although it is not expressed in any way in the Incorporation papers, has, nevertheless, been taken care of satisfactorily. The accountings for interest upon the indebtedness and the various other details in connection therewith have been and will be carried on so that there can be no question arising as to these matters. The only difference will be that of form.
>
> The statement in X. Y.'s opinion which reads "We pre-

---

*The use of initials is ours. †The omission is ours.

pared to meet your desire to secure to the corporation at least for a period of substantlally three years the same personal management and direction which has been enjoyed by your American branch," needs a little explanation. Usually voting trust agreements are made for this purpose and under ordinary circumstances that reason is given for the execution of such voting trust agreements. The real reason in this incorporation for executing the agreement and the transfer of the stock to voting trustees was for the sole purpose of putting the stock in such legal form that in case any action was taken by the Government here that your interests could not in any way be legally jeopardized—that the business should go on without interruption. In other words, there is and was no intention of perpetuating anybody in the management or direction of the American branch.

I have gone into these matters in details because I realize that it is difficult for you at so great a distance, and with your known objection to corporate form, to understand the reasons underlying such a move. I can give you my personal assurances that the incorporation is the only solution open to us at the present time, and although we may disagree as to the conditions and as to the seriousness of the situation, nevertheless, in my judgment the step was not only wise and proper, but absolutely necessary. I should have deemed it a breach of duty to you to have subjected all of your assets in this country to the dangers that were apparent, and this fact alone was of sufficient weight to determine my agreement with the opinion of X. Y. Without trying in any way to seek justification for the action taken, as I do not deem that necessary, I think it will be all too apparent to you that the consummation of the proposition was but an honest fulfillment of a duty to you to protect your property, and in the last analysis the facts must be judged on this basis. The only misgivings that I have had were that we could not advise with you more fully before completing the work, but as I have already said, this was impossible in the nature of things, nevertheless such communications as were possible to send were sent.

To sum up the whole matter, I would say that we have given you an insurance policy upon your assets here, and, like all insurance policies, this one is subject to cancellation.

I hope that all of my good friends are in good health and that peace will soon be concluded so that we may all return to the normal business relations.

With my kindest and best respects and wish to you all, I am

Very sincerely yours,

(Signed) — — — —.

The assets thus transferred to the corporation amounted to about $3,250,000, which did not include the profits made by the business in 1915, amounting to about $1,200,000, and the profits of 1916, amounting to $2,000,000. Between September, 1915, and February 3, 1917, Beer, Sondheimer & Co., of New York, transferred to Beer, Sondheimer & Co., of Frankfort, $2,047,000. The last remittance of $700,000 was made on February 3, 1917, the very day on which Count Von Bernstoff received his passports and was sent out of the country. When this happened and it became clear that the United States and Germany were on the brink of war, Elkan and Frohnknecht, to further make it impossible for the Government to seize the German property in their possession, caused to be transferred to the corporation 7000 out of the 10,000 shares of the stock of the corporation which had been issued to the Frankfort firm as consideration for the transfer of the assets to the corporation, and to effect this transfer, they did not hesitate to cause the name of the Frankfort firm to be indorsed upon the back of the stock certificate without any apparent authority. The other 3000 shares of stock they claimed to have bought from the Germans in 1916 at the rate of $80 per share, when the book-value thereof was in excess of $300 per share and in the face of a profit made by the business in that one year of $2,000,000. Thus the two individuals claimed to become the owners of all the business and assets formerly belonging to their German principals, less the portion of profits sent to Germany as above stated.

Though they have been in this country since 1906, Elkan and Frohnknecht did not become citizens till 1917. One of them became a citizen after Von Bernstoff got his passports and the other was admitted to citizenship in May, 1917, after we were at war with Germany. There is evidence to indicate that their sudden desire to embrace our citizenship was only a 'war measure' after all and that they asked for and obtained the approval of the Frankfort firm to their action.

The foregoing is but a bare outline of what the investigation disclosed, but it is sufficient to indicate that the transfers were void as against public policy, and in consequence thereof the Alien Property Custodian demanded and took over the entire business and assets of Beer, Sondheimer & Co., as German property.

As to L. Vogelstein & Co.—It had been the custom for years for Vogelstein to make annual settlements with Aron Hirsch & Sohn and to send and receive annual accounts upon the basis of which respective shares in the profits were determined as between Aron Hirsch & Sohn and L. Vogelstein & Co. The last accounting was had as of the end of 1914. Owing to the War it has been impossible for accountings to be had since that time. At the end of 1916 Vogelstein bought out the interests in the firm of L. Vogelstein & Co. owned by Ernest G. Hothorn and he then formed a corporation under the laws of the State of New York under the name of L. Vogelstein & Co., capitalized at $5,000,000, and transferred to the corporation all of the assets of the firm of L. Vogelstein & Co. in consideration of the issue of the entire capital stock. At that time the books of L. Vogelstein & Co. showed that the firm was indebted to Aron Hirsch & Sohn for its share of the profits of the American business and balances due in the sum of about $3,900,000. But inasmuch as there was no way of determining what profits, if any, Vogelstein was entitled to receive from the European business of Aron Hirsch & Sohn, no accounts having been stated between the parties since the end of 1914, there was no way of determining what amount was really due to Aron Hirsch & Sohn. Under these circumstances Vogelstein placed the entire 50,000 shares of stock in escrow with his attorneys, setting aside 39,000 shares thereof to be held to await a final accounting between the two firms. The Alien Property Custodian made a demand upon the attorneys who held the stock in escrow for the surrender to him of the interest of Aron Hirsch & Sohn in said stock.' The entire 50,000 shares of stock, being the total capitalization of the corn-pany, were turned over to the Custodian and he took control of the business.

As to American Metal Co.—In 1917 on the last increase of the capital stock of the American Metal Co., the Metallgesellschaft and the other German interests allied with it (not including Henry R. Merton & Co.) who appeared as stockholders of the American Metal Co., held 34,644 shares out of the 70,000 shares of stock outstanding, the Henry R. Merton & Co. and the interests allied with it held 16,736 shares, and the balance of 18,620 shares were held by Americans. The Americans were at this time in control of the board of directors of the company and all the officers were American.

The Alien Property Custodian demanded and received all of said 34,644 shares of stock owned by Germans, and appointed 5 out of the 15 directors of the company to represent him in the conduct of the affairs of the corporation.

In dealing with the German interests in the American Metal Co., L. Vogelstein & Co., and Beer, Sondheimer & Co., the Alien Property Custodian sought, not only to take possession of all such alien property, but also to eliminate as far as possible for all time German interests and German influences which existed and had been exercised in this country through the control of these three companies, and it is believed that the disposition made by the Custodian of the German interests in these companies has been such as to effectually eliminate all present and, it is hoped, future German control in the metal market and the metal industry of this country.

THE DISPOSITION OF PROPERTY BY THE CUSTODIAN

As to Beer, Sondheimer & Co.—The business of Beer, Sondheimer & Co. is in process of liquidation. This includes not only the corporation Beer, Sondheimer & Co., but also its subsidiaries, the National Zinc Co., the Norfolk Smelting Co., and the Cuba Copper Leasing Company.

When the Custodian took over the business of Beer, Sondheimer & Co. he placed it in control of a board of directors designated by him. Elkan and Frohnknecht maintaining that they owned all the stock of the corporation, filed a claim therefor, and thereafter brought suits to recover the same. These suits, however, have been withdrawn, and the Custodian through said board of directors is proceeding to liquidate the company, and as soon as the business has been liquidated the corporation itself will be dissolved, and Beer, Sondheimer & Co. will entirely have disappeared as a factor in the zinc and copper situation both in the purchase and sale of ores and in the control of mines and smelters. As pointed out above, the Frankfort firm of Beer, Sondheimer & Co. was a stockholder in the Minerals Separation Companies. In 1913 the Frankfort firm transferred to its American branch its interest in this stock, and when the American Minerals Separation was formed in 1916 under the name of Minerals Separation North American Corporation the stockholders of the predecessor, British Minerals Separation Co., became entitled to exchange their shares for the stock of the new company upon the basis of one share of the old stock for two of the new. Thus Beer, Sondheimer & Co. became entitled to receive 65,230 shares of the stock of Minerals Separation North American Corporation. In addition to this amount of stock, Beer, Sondheimer & Co. had received from Minerals Separation North American Corporation 35,000 shares of stock as a consideration for the cancellation of the exclusive agency of Beer, Sondheimer & Co. theretofore granted by the British Minerals Separation Co., thus giving to Beer, Sondheimer & Co. a total of over 100,000 shares of the stock of Minerals Separation North American Corporation out of a total issue of 500,000 shares. The Custodian took over all of said 100,000 shares (in form of voting trust certificates) as property of Beer, Sondheimer & Co., of Frankfort. This stock will likewise be disposed of by the Custodian and will go into American hands. Beer, Sondheimer & Co.'s control over the important flotation process has been destroyed.

As to Vogelstein & Co.—As in the case of Beer, Sondheimer & Co., when the Custodian took over the business of L. Vogelstein & Co., he placed in control thereof a board of directors designated by him. Subsequent investigation by the Custodian disclosed that Vogelstein, who was a naturalized American citizen, had a preponderating interest in the assets of the corporation, and inasmuch as it has as yet been impossible to obtain from Aron Hirsch & Sohn an accounting so as to determine that concern's exact interest in the assets of L. Vogelstein & Co., an arrangement has been perfected between the Custodian and Vogelstein whereby all of the stock of the corporation has been put into a voting trust for a period of five years, the Custodian naming two of the three voting trustees. Thus the control of the corporation for the next five years will be in the hands of trustees appointed by the Alien Property Custodian. Vogelstein has agreed not to resume his relations with the Germans during this period of five years and to conduct the business of the corporation as a purely American concern. The voting trust certificates have been made assignable only to Americans. Vogelstein has agreed to pay to the Custodian $1,668,671.49, being the amount of the apparent indebtedness from him to the Hirsches as of April 30, 1916, and has agreed to pay to the Custodian all additional moneys that may be found to be due to the Hirsches upon a final accounting which is to be had within six months after the declaration of peace. Thus circumscribed and guarded, the control of the business has been turned back to Vogelstein, the Custodian retaining two out of the five places on the board of directors as long as the Custodian may have any interest in the business.

As to American Metal Co.—Soon after the trading-with-the-enemy Act became a law, the Americans in control of the American Metal Co., not only promptly filed the report required by the act and disclosed therein the German ownership of about 49% of the stock of the company, but offered to co-operate with the Custodian in any direction looking to the elimination of the German interests. An investigation of the affairs of the company was courted and at the instance of the War Trade Board, such an investigation was made and subsequently the Alien Property Custodian likewise made an investigation of his own. The officers of the company heartily co-operated with the Alien Property Custodian, which resulted in the first instance in the transfer to the Custodian of the stock belonging to the Germans. The Custodian was satisfied with the good faith of the management of the corporation and, therefore, designated but five out of the 15 directors of the company.

By agreement between the Alien Property Custodian and the American stockholders, together controlling 53,264 shares (out of 70,000 shares outstanding) all of said stock has been placed in a voting trust for a period of five years. The Alien Property Custodian is entitled to receive voting trust certificates representing the 34,644 shares of stock formerly held by enemy-aliens. It is his purpose to offer these certificates for sale to the American public at public auction.

The voting-trust agreement provides that the Alien Property Custodian shall appoint all five of the voting trustees. He has already appointed three trustees, who are now in actual control of the management and policy of the company. The trustees are Joseph F. Guffey, Henry Morgenthau, and Berthold Hochschild. Mr. Hochschild is one of the founders of the company and has been chairman of the board of directors for several years. The Alien Property Custodian will appoint the other two trustees after he shall have sold the voting trust certificates held by him.

The policy of the Alien Property Custodian to sell only to Americans will be strictly adhered to in this instance and none of the voting trust certificates will be permitted to go into any but American ownership. The immediate result is that 76% of the stock of the company will be owned by American citizens. The Alien Property Custodian is in correspondence with the British authorities with a view to the deposit under the voting-trust agreement of the 16,736 shares held by Henry R. Merton & Co. and its allied interests. It is hoped that such action will be taken in the near future. When this has been done, the Alien Property Custodian believes that all German ownership and influence will be effectually eliminated from the company.

The Result

To summarize the result of the activities of the Alien Property Custodian in so far as they affect German interests and German influences in the American metal market, it may be said that finding those interests and influences centred in three well-defined corporations, American in name but all controlled by the German metal triumvirate, the activities of which three corporations were not confined solely to the United States but penetrated into Mexico and South America, owning mines, smelters, refineries, oil concessions, railways, dealing in every known metal, doing a business which annually ran into hundreds of millions of dollars, he has succeeded in thoroughly Americanizing two of these concerns and liquidating the third, thereby entirely eliminating German influences in our metal markets and our metal industry.

The German metal octopus had spread his tentacles across the ocean and over the United States into Mexico and South America, but for the present surely, and for all time it is hoped, he has been driven back and a wall of Americanism erected which, it is hoped, he will never be able again to scale.

Pyrite and Sulphuric Acid

By R. R. HORNOR and A. E. WELLS

*Pyrite. As a result of further curtailment in acid manufacture the demand for pyrite and sulphur is not active. Many of the large consumers still have sufficient stocks on hand to take care of their immediate needs, consequently they are not disposed to make contracts for new material, preferring to wait until conditions are more settled. The producer, therefore, is confronted by a restricted demand, and finds it difficult to dispose of his product unless he happens to hold long-term contracts, providing for his entire output. It is thought by those who have an intimate knowledge of the industry that conditions will improve speedily, and within the next two or three months there should be a brisk demand for both pyrite and sulphur. The outlook in some of the industries that use large quantities of sulphuric acid, particularly oil and steel, is encouraging.

Sulphuric Acid. There is little demand for acid, and in spite of the fact that production has been greatly curtailed, there are heavy stocks on hand. Consumers of acid, knowing that the stocks are heavy, are not coming into the market, preferring to wait till the acid is offered. Producers are striving to maintain the price to at least equal to the costs, and are curtailing production to prevent a larger surplus being made. In the Mississippi valley where there is a large production of by-product acid, the price of this is lower than in the East.

The recent sale of acid at the plant of the Aetna Explosives Co. by the French government had a rather disturbing effect on the market, even though the purchaser stated that the goods purchased would not be offered for sale. The average price of 66°B. acid in the New York district is $18 per ton.

Some export business, especially to South America, is being done, and it is hoped that this may help to relieve the congestion of acid in the domestic market. It was hoped that the congestion would be relieved to some extent by the exportation of super-phosphate to Europe, but owing to various reasons, the amount of this fertilizer shipped has been below expectations.

In the suit of the Union Sulphur Co. v. the Freeport Sulphur Co., the U. S. Circuit Court held that the Frasch patent lacked inventive substance.

*Abstract from March report of U. S. Bureau of Mines.

Leaching of Oxidized Copper Ores With Ferric Chloride

By R. W. PERRY

INTRODUCTION. Numerous attempts to leach both oxidized and sulphide ores of copper by use of a solution of ferric chloride have been made, with regeneration of the solution after precipitating the copper on iron, either by the oxidizing action of chlorine, oxygen, or electricity.

The only one that ever went beyond the experimental stage was the Doetch process, applied to heap-leaching at Rio Tinto, where the solution was regenerated by chlorine, formed by heating ferrous sulphate and salt in a reverberatory furnace. I am not aware of any serious attempt having been made to use oxygen to regenerate ferric chloride, but there should be no serious difficulty beyond the amount of air required, as shown in the regeneration of ferric sulphate at Cananea and the great loss of the solvent by the precipitation of basic chlorides and oxy-chlorides. As will be seen later, this regeneration is continuous if the pulp is agitated in a ferrous chloride solution, and the ultimate extraction will probably be the same with a ferrous chloride solution with agitation as with a ferric chloride solution.

Ferrous chloride was successfully used as a solvent at Ore Knob, in North Carolina. Under the conditions of applying the solvent there, more or less ferric chloride must have been formed, if only momentarily. The Slater process as practised at Winona, in Michigan, depended upon the oxidation of ferrous chloride, by chlorine produced by the electrolysis of salt carried in the same solution.

The Walker River Copper Co. of Yerington, Nevada, has been experimenting with a process in which the regeneration of ferric chloride is caused by the precipitation, by electricity, of part of the iron in a ferrous chloride solution, with a corresponding regeneration of ferric chloride. The information concerning this process, as here published, has been taken from the operation of this company's experimental mill at Yerington, and supplementary laboratory work and small-scale tests, made while I was chemist there.

CHEMISTRY. The process* is based on the following generally accepted chemical reaction:

1. $3CuO + 2FeCl_3 + 3H_2O = 3CuCl_2 + 2Fe(OH$
2. $3CuCl_2 + 3Fe = 3Cu + 3FeCl_2$
3. $3FeCl_2 +$ Electricity $= Fe + 2FeCl_3$

In the first equation, the solution of the copper is accompanied by the formation of varying amounts of ferrous chloride and basic chlorides in a neutral solution. Owing to the hydrolysis of the ferric chloride solution, there is no neutral solution of ferric chloride, and the term as used here means a solution containing no free acid beyond that formed by the hydrolysis of the ferric chloride itself. The reactions show a complete regeneration of the solvent and also a production of one-third the iron necessary to precipitate the dissolved copper. Two to three per cent of salt was carried in a solution to increase the resistance of the electrolyte and to hold the cuprous chloride in solution, but no cuprous chloride can be formed while ferric chloride is present.

THE ORE treated was completely oxidized, no sulphides being present, in an altered monzonite gangue. The copper was present principally as malachite, accompanied with about 0.3% of cuprite, and some silicate. An incomplete analysis of the ore gave the following composition:

	%		%
Insoluble	63.0	CaO	0.7
Alumina	10.5	MgO	1.3
Iron	6.0	Ag ..	.01 oz

A very small amount of the lime is present as calcium carbonate, due to atmospheric action near the surface, but the greater part is a constituent of the feldspars and is not affected by either ferric chloride or dilute sulphuric acid.

THE MILL. The accompanying flow-sheet shows the arrangement of the mill. The ore was crushed to pass a 20-mesh screen and was agitated for seven hours in a weak ferric chloride solution, at a temperature of 70 C., there being a continuous overflow of slime from the first agitator to the thickener, the overflow from which went alternately to each of two settling-tanks, from which it was by-passed to the pregnant-solution vat, or drawn through the leaves of the Moore filter to clarify it when necessary. At the temperature employed, the slime and the ferric hydrate formed during the solution of the copper, settled readily, and it was necessary to filter only a small part of the solution. The underflow from the Dorr thickener went to the Moore filter, where it was washed and discharged, the resulting solution going from a montejus to the pregnant-solution vat.

The copper-bearing solution was pumped from the pregnant-solution vat, by a hard-rubber reciprocating pump, to two revolving drums with oak staves and mounted on trunnions, where the copper was precipitated on iron turnings and shavings, the copper being separated in two small cones, and the overflowing ferrous chloride solution, going to the catholyte-storage vat, from which it was circulated by an ordinary centrifugal pump through the electrolytic department.

The arms of the Dorr agitators were covered at the

---

*The patent rights of this process are owned by the Midland Ores & Patents Company.

ends, except for a narrow slat, and only a small proportion of the pulp in circulation was allowed to discharge there, most of it overflowing near the centre of the tank. The flow of pulp from one tank to another was regulated as shown in the sketch, by means of a segment of a launder inside of each agitator, occupying about one-fifth the perifery of the agitator and receiving the discharge from the ends of the arms. The discharge from the last agitator went to a Dorr three-stage classifier and washer, the overflow of slime returning by means of an air-lift to the first agitator, and the sand discharging into two 5 by 12-ft. tanks, with filter-bottoms, where the remaining soluble metal was removed with water-washes, the first wash being returned to the circulating system, the weak final washes being run to waste after precipitation on scrap-iron.

Fresh strong solution from the anolyte vat was added in a launder connecting the first and second agitators, and as its volume was small in proportion to the circulating solution and its action on the copper minerals very rapid at this point, the actual extraction was done in a weak solution. The average composition of the solution is shown in the accompanying table.

	$FeCl_3$ %	$FeCl_2$ %	
Overflow from 1st agitator	0.72	0.07	to thickener
"	.0 76	0 26	
2nd	.0 81	0 15	
3rd	.0.76	0 17	
4th	6.72	0.33	

Fresh solution was added in sufficient quantities to have enough ferric chloride for the solution of all the copper contained in the ore, according to the equation given above.

SOLUTION. It will be noted that there is more ferric chloride in the discharge from the last agitator than at any other point in the system. This is to be accounted for by the small amount of copper dissolved there, the destruction of ferric chloride being slower than its formation by the air used in agitating. In the first agitator the ferric chloride contents are reduced to a very small quantity through contact with fresh ore, the action on the larger quantity of copper present here being more rapid than the oxidizing effect of the air. The sample from the discharge of the first agitator was taken from the launder after the fresh strong solution had been added, showing the quick action of ferric chloride at this point. Table No. 2 shows the extractions obtained at different stages.

Table No. 2

Discharge from Agitator

	No. 1		No. 2		No. 3		No. 4	
Feed Copper %	Copper %	Extraction %	Copper %	Extraction %	Copper %	Extraction %	Copper %	Extraction %
4.6	1.15	75.0	0.76	83.3	0.40	91.3	0.4	91.3
3.2	0.90	71.8	0.60	81.2	0.50	84.3	0.5	84.3
3.6	1.60	55.5	1.08	70.0	0.66	81.6	0.47	81.3
3.4	1.60	52.9	1.20	64.7	0.80	76.4	0.50	85.3
2.4	0.96	60.0	0.70	69.8	0.55	76.0	0.45	80.1

The extractions in the last column were the total extractions, as there was no further action in the classifier or filter-tanks. No samples were taken regularly from the slime as the quantity produced was small. What samples were taken assayed from 0.25 to 0.3% copper, which was probably present as cuprite.

PRECIPITATION of the copper was effected on iron turnings, and the iron recovered from the electrolytic plant in two revolving drums. The solutions were heated by steam before going to the drums, and the copper precipitated in the upper drum was settled in a cone, after which the solution passed through the lower drum, where precipitation was completed. Iron was charged intermittently as required, and probably no more than 300 lb. was present in the drums at one time. Although the turnings and shavings used were rusty and covered with grease, the precipitation was complete and the total consumption of iron amounted to only 1.5 lb. per pound of copper recovered, including that from the electrolytic department.

The precipitate was very fine, but settled readily, and as first obtained assayed over 80% copper. It oxidized rapidly on drying and as shipped was of the following composition:

H_2O	1.8%	Ag	0.3 oz.
Cu	66.9%	Cl	1.8%
Fe	10.0%		

When using the copper cathodes referred to below, part of the solution was diverted from the first drum to a stripping-tank in which the cathodes with their deposit of iron were immersed and the iron removed by the action of the copper solution and some manual labor, with brushes and scrapers.

REGENERATION OF FERRIC CHLORIDE. The electrolytic regenerating plant consisted of a 25-kw. motor-generator set delivering 1000 amperes at 25 volts, driven by power from the Truckee River Power & Electric Co. with the necessary switch-boards, etc. It contained 10 cells 24 by 32 by 35 in. connected in series of five. Each cell contained 9 cathodes and 10 anodes, the anodes being carbon and enclosed in canvas diaphragms. Solution was drawn from the catholyte-vat to small distributing-tanks above the cells to which it flowed by gravity, the quantity going to the anode compartment being regulated according to the quantity of ferric chloride required by the ore undergoing treatment or the current available.

As first started, the electrolysis was completed in one cell; but it was found that the oxidation of the ferrous chloride was under better control if it was not carried to completion in the same cell, so in the latter part of the work, the anolyte flowed through the series of five cells, entering the first at the bottom of the diaphragm compartment and discharging at the top through rubber connections to the bottom of the next cell, and an incomplete oxidation allowed to occur in each cell. The catholyte circulated through each cell separately, entering at the bottom and discharging at the top to a launder returning to the catholyte-vat.

A copper screen was employed for the cathodes at the beginning, in order to get an adherent deposit of iron, with the expectation that this iron would be dissolved in the stripping-tank in contact with the copper solution. The iron deposit proved to be so adherent that, on contact with the copper solution, the surface only was affected, requiring continuous work with brushes and iron scrapers to remove it. The rough handling during this operation caused the rapid deterioration of the screens and the labor cost was excessive. Before the plant closed, cathodes of sheet-iron, both plain and galvanized, were tried, with much more satisfactory results, the iron being deposited in a soft spongy form that could be easily removed, and while the plant was not run long enough to determine the life of these cathodes, it was demonstrated that their use would be economical both as to labor and material, as they could be used in the drums for precipitating copper when too much worn to be of value as cathodes. More care would be needed to get a clean precipitation of copper before the solution was electrolyzed, and their deterioration would be caused principally by the trace of copper remaining in the electrolyte.

FIG. 3. FLOW-SHEET OF WALKER RIVER EXPERIMENTAL PLANT

It was found that 431 ampere hours is required to precipitate one pound of iron, assuming a current efficiency of 100%, of which 70% was attained in practice. In one run 2822 kw-hr. precipitated 1980 lb. of iron and regenerated the corresponding amount of ferric chloride. Since the plant was not run at full capacity at this time and there was more or less trouble with the circulation of the electrolyte, it should be easy to attain a current efficiency of 75%.

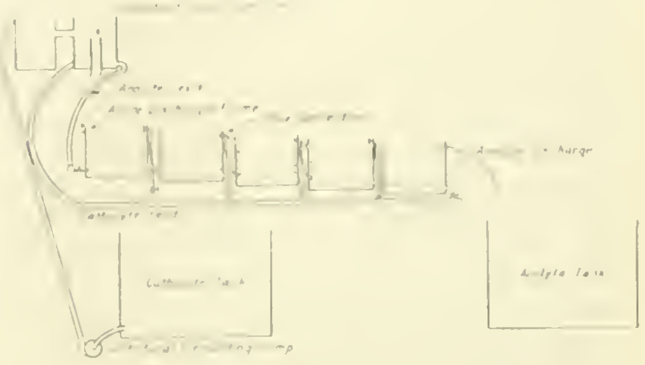

FIG. 1. DETAILS OF ELECTROLYTE CIRCULATION

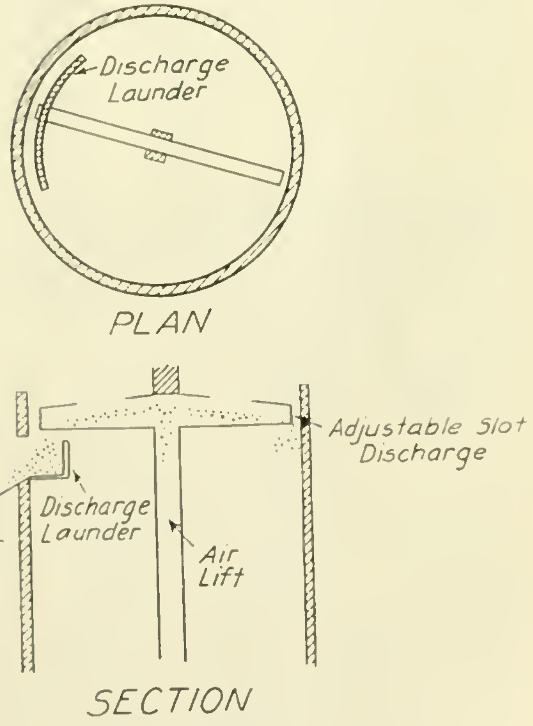

FIG. 2. SKETCH OF AGITATOR DISCHARGE

TROUBLES. At times much trouble was experienced with chlorine fume, which was apparently due to the poor circulation of the anolyte caused by the clogging of the connections to the cells. Unless hydrochloric acid to the extent of several hundred pounds per day was used in the catholyte, a slimy gelatinous precipitate of ferrous hydrate formed, becoming very troublesome in the small connections. The formation of this precipitate may have been caused by the decomposition of the salt with a production of sodium hydrate.

One of the principal troubles in operating was due to the bending of the thin cathodes, so that they touched the diaphragms in places and the iron deposit adhered to the canvas, not only causing a short circuit at this place, but also tearing the canvas when the cathode was removed. The life of the diaphragms was not determined, but the canvas showed little deterioration when the plant was operating normally. The trouble caused by the bending of the cathodes could have been easily remedied by increasing the distance between the electrodes to 2 or 2½ inches without causing any material loss of current-efficiency. The clogging of the connections could have been easily avoided by making some changes in them. At the time the plant closed, steps were being taken to make both these changes. There was no difficulty in securing a complete oxidation of the ferrous chloride in the anolyte, but on account of the danger of chlorine fume, when the oxidation was carried to completeness, owing to the irregularity of circulation, some ferrous chloride was generally allowed to remain unoxidized. Some typical analyses of the anolyte and catholyte are given.

	$FeCl_2$ %	$FeCl_3$ %	NaCl %
Anolyte	0.02	2.46	2.08
	0.80	1.60	2.00
	0.40	2.10	1.94
	0.50	1.90	1.90

+30	31.25	2.96	30.20	0.58	37.3	2.90	37.3	0.50
+40	13.76	3.04	15.65	0.65	27.0	3.05	25.0	0.36
+60	.		.		11.0		11.6	0.36
+80							16.8	0.39
+100	21.25	3.22	23.15	0.58	35.7	3.25	9.3	0.58
−100	21.25	4.16	18.50	0.52		...	...	...

The object in separating the different sizes in these tests was to avoid the possibility of the charge becoming clogged with the ferric hydrate precipitate, and it was also the intention to utilize the present experimental plant in connection with the leaching-plant if the experiments proved successful. Charge No. 6 run on unscreened ore proved that this clogging would take place on a charge of this character, because at the end of 60 hours, while a good extraction had been obtained, percolation had slowed down to an appreciable extent, and if this took place in a shallow charge, it was sure to be worse in a charge on any depth.

The variations in the extraction proved that as good work could be done with cold solutions as at higher temperatures, with a longer contact, and the loss of ferric chloride was considerably lower at the low temperatures.

The loss of ferric chloride in these tests was 8 to 12 pounds per ton as against a loss of 20 pounds at a temperature of 70°C. Treatment of the tailing from several of these tests with a strong solution of ferric chloride at just below the boiling-point reduced the copper contents to 0.3%, which was assumed to be the lowest obtainable on this ore with ferric chloride.

Solutions of three strengths were employed in these tests, as it was thought advisable to use a comparatively weak solution on the fresh ore in order to destroy the last trace of ferric chloride in the solution and finish with a strong solution to obtain the highest extraction. The use of a strong solution to increase the extraction was not found necessary, as a weak solution would do the same work.

Table No. 3 is a record of an average run, showing analyses of the solutions used at different times of contact.

Table No. 3

" 48 " "	0.79	3.97	0.52
" 96 " "	1.08	4.37	0.68

This test differs from regular test No. 10 in that each solution was allowed to act for a longer length of time than necessary, as the same extraction was obtained in test No. 10 in 93 hours total contact with the three solutions. The increase in copper contents of the solutions at the end being only apparent gains, due to the evaporation of the solution. It will be noted that there is considerable solution of copper by the ferrous chloride in the first solution after the ferric chloride is destroyed. There is also an apparent gain in ferric chloride in the last solution, due to the solution of ferric hydrate by strong ferric chloride. In some tests this increase was considerable.

Several tests were run with the addition of hydrochloric acid to prevent the precipitation of basic salts, but were not successful, unless sufficient acid was used to make the process an acid leaching one, as the acid was consumed by the copper minerals or dissolved the precipitate of ferric hydrate and became neutral.

Difficulty was experienced in determining the free acid in these solutions. The method used was to precipitate the iron and copper with mono-sodium phosphate and titrate the acid with sodium hydroxide solution, using methyl orange for the indicator. This gave good results on straight ferric chloride solutions, but was only accurate to 0.2% of the solutions in use. It was finally discovered that the copper in the tailing could be reduced to 0.1% by a subsequent treatment with hydrochloric acid if the ferric hydrate precipitate was removed by a preliminary wash and agitation. The use of 60 lb. of commercial hydrochloric acid per ton was sufficient for the solution of 8 to 10 lb. of copper in the tailing after removing the ferric hydrate. This was best added in one strong solution which was washed out after a few hours contact. If this same amount of acid was added without removing the ferric hydrate, the copper contents were reduced to 0.2%, or 4 lb. per ton. In this case the tailing in the upper part of the tank showed a much higher extraction than the lower part. As the removal of the ferric hydrate would require an extra handling and classification, it would probably not be desirable to do this in practice for the two pounds of copper that could be recovered. Since the addition of considerable quantities of hydrochloric acid is required to make up the loss of ferric chloride, incurred in treatment, it would be best to add it at this point on account of the extra recovery.

It has been estimated by manufacturers that commercial hydrochloric acid can be manufactured under local conditions, giving credit for the sodium hydroxide produced, at past prices for half a cent per pound, so the cost for solvents at these prices would only amount to 30 cents per ton of ore treated.

Loss of Ferric Chloride. This loss is caused in several ways. (1) There is some loss by volatilization at high temperatures. (2) CaCO and MgCO cause a loss of approximately four pounds in the treatment of this ore, and, of course, ores carrying any appreciable amount of these carbonates cannot be treated by this solvent, as it attacks them very energetically. (3) There is supposed to be some formation of oxychlorides by the action of air used in agitation on ferrous chloride. (4) The main cause of the loss is the formation of basic chlorides: while little is known concerning their formation, it has been noted by others. Sims and Ralston, in their article in 'Metallurgical and Chemical Engineering', October 1, 1916, entitled 'Electrolytic Recovery of Lead from Brines', offer this explanation of the non-accumulation of iron in the cyclic leaching of lead ores: "Iron builds up slowly in the solution with each cycle, until it reaches the neighborhood of 1½%, when it seems to approach equilibrium. As an amount of iron (one pound for three pounds of lead precipitated) equivalent to the amount of lead precipitated enters the solution during each electrolysis, then iron must also be thrown out of solution during each cycle. Analysis before and after a leach shows that it is left in the ore. As the leaching solution, although acid at the start, becomes neutral before the end of each agitation with the ore, the iron is probably hydrolyzed to either the hydroxide or to a basic chloride. When the electrolysis of the solution has been completed most of the iron is present as ferrous chloride, and it is obviously only the ferric iron that is precipitated. However it is possible in a neutral solution for the ferrous chloride to oxidize to a basic ferric chloride."

When ferrous and ferric chlorides are heated together in the same solution, some hydroxides or basic chloride separates, but the amount is not large, although the loss from this reaction might be considerable if continuous as in the operation of a plant. As explained above, the loss of iron by hydrolysis could not explain the loss of ferric chloride in this process, since the hydrochloric acid would become available for the solution of the copper and on completion of the cycle, would appear again as ferric chloride, and there would be no apparent loss of iron. Therefore the precipitation of basic chlorides would seem to be the only explanation for this loss. In the operation of the plant some 20 lb. of salt was lost per ton of ore.

Application of the Process. Further experimentation with the process was abandoned by the Walker River Copper Co. because the ore under consideration was so well adapted to leaching with sulphuric acid, which process could be used with a much simpler mill arrangement.

Any form of mill using the ferric chloride process would require the separation of the fine and coarse material and the treatment of the fine by agitation, since percolation of a fine charge would be stopped by the precipitation of ferric hydrate. Heat would also be required during agitation since the precipitate of ferric hydrate would impede filtration unless heated to 100°F. Of course, this extra expense would not be prohibitive on account of the small quantity of material agitated, but the actual operation of the plant would be more complicated and require greater attention.

This process, like the sulphuric acid process, cannot be employed on ores containing any amount of lime as carbonate on account of the consumption of the solvent. It would seem to be well adapted to the treatment of ores which show a high consumption of sulphuric acid due to the easy solubility of iron and aluminum minerals, and might prove valuable in treating mixed sulphide and oxide ores containing silver, as ferric sulphide in hot solutions is a good solvent of silver and copper sulphides.

In any case a supply of cheap hydrochloric acid would be a necessity, and on account of the difficulties of transportation and the small percentage of hydrochloric acid in the commercial acid, it would have to be manufactured at the plant. A fairly cheap supply of salt is available in many parts of the west, as at Salt Lake, and western Nevada or Kansas salt could be secured for Colorado and New Mexico at rates that would allow its use. With power at one cent per kilowatt-hour and making allowances for the sale of the sodium hydroxide produced, commercial acid should be produced for less than one cent per pound. However, anyone contemplating this method should proceed with caution, as the cost of the acid would depend primarily on the market for sodium hydroxide. With power at 1 cent per kw-hr, an acid at one cent per pound, the cost of solvents, regenerating solution, and iron for precipitating copper would amount to about $1 per ton on an ore carrying 2.5% copper and using 60 lb. of commercial acid to replace the ferric chloride lost.

Numerous petty annoyances would be encountered in the use of diaphragms, but I don't think they be serious, and the process could undoubtedly be made use of in localities where sulphuric acid was not available.

Items From the Annual Report of the Phelps Dodge Corporation

The 43-page report of the Phelps Dodge Corporation, covering the year 1918, contains the following notes:

The Copper Queen reduction works at Douglas treated a total of 1,311,742 tons of ores, concentrates, and other materials, yielding 192,063,212 lb. of copper, 32,709 oz. of gold, and 2,307,307 oz. of silver, a slight increase over the quantities in 1917. A copper-casting furnace was erected, also a new superheater and a coal-pulverizing plant for use on one reverberatory furnace. These works employed 1531 men.

The mill at the Detroit mine at Morenci treated 449,990 tons of ore assaying 1.91% copper. The concentrate —57,719 tons—carried 11.32% copper, and the ratio of concentration was 7.796:1. The saving, the average by four methods of calculations, was 76.22%. Additions were made to the flotation department, and by substituting electric motors for gas-engine drive a more dependable and economical power was obtained. This was done by erecting two Diesel engines to drive generators. The concentrator employed 112 men, and the smelter, where 154,216 tons of charge was reduced, 102 men.

At the Burro Mountain mine in New Mexico, the cost of ore extraction was reduced by the better condition of stopes and to increased drawing from the broken ore-reserves in the shrinkage-stopes. The caving system is employed successfully.

The mill treated 585,083 tons of 1.928% copper ore. This carried 3.094% moisture. The concentrate produced amounted to 53,146 tons, assaying 14.875% copper, and the ratio of concentration was 11.009:1. As the ore was of lower grade than in 1917, and in a more advanced stage of oxidation, the saving dropped from 72.301 to 70.065%. The daily tonnage was 1710, using 737 gallons of fresh water per ton, and 10.159 kw-hr. of power per ton milled. The single-unit flotation machines were replaced by those of three units, improving recovery. Experiments show that fine grinding in closed circuit, more and improved flotation apparatus, and additional tables below the flotation units, will give a better saving, so plans for this object are in preparation. The leaching-beds at the mine were irrigated intermittently during 1918, dissolving 8.9% of the copper in the ore, making 33.8% in two years. This work has given valuable data as to the possibilities of the process.

Four Diesel engines are now available in the power-plant and give excellent service. The Diesel compressor was entirely satisfactory.

The Stag Cañon mine at Dawson, New Mexico, supplies the Phelps Dodge smelters with coke. Last Year's output was 281,916 tons of coke from 470,924 tons of coal, a yield of 64.8%. The percentage of ash is 18.09. Edison electric safety-lamps are used in the mines.

Many improvements were made at the Moctezuma copper mine at Nacozari, in Sonora, Mexico, and development of ore was very satisfactory. The hoist and compressor plants were increased, and doors and sprinkler-apparatus were installed for protection against mine fires.

More mechanical flotation apparatus was erected at the mill, and a large pneumatic unit was being put in during February 1919. The mill treated 762,089 tons of 3.392% ore, equal to 2320 tons daily (328.5 days). General concentrates amounted to 159,246 tons, containing 12.240%, and filter (flotation) concentrates 14,882 tons, averaging 16.913% copper. The ratio of concentration was 4.377%, and recovery, by four methods of figuring, 85.575%. Water used per ton of ore was 666 gallons, and power 12.535 kw-hr. Diesel engines are now being erected in the power-plant.

The Bunker Hill mine at Tombstone, Arizona, produced 19,312 tons of ores, yielding 1335 oz. of gold, 276,007 oz. of silver, 448,616 lb. of lead, 39,209 lb. of copper, and 417 tons of manganese. The last item represented shipments to the East, but 3952 tons of manganese tailing, carrying 34,971 oz. of silver, was sent to the smelter at Douglas.

The mercantile stores of the Corporation sold goods worth $10,408,913. The net profit was 7.98%, compared with 8.42% in 1917, and 10.38% in 1916. These stores employed 644 people. The balance-sheet shows that merchandise for sale is valued at $2,622,161.

THE quantity of corundum and emery mined in the United States last year was 10,139 short tons. The quantity of crude emery and corundum marketed was 8702 tons, valued, f.o.b. mines, at $95,248. The output was 45% less than in 1916 and 52% less than that in 1917. The output in those two years, however, was abnormally large, and was stimulated by the demand due to the War, which required enormous quantities of abrasives for making munitions and other articles needed for military use, and prevented the importation of foreign corundum and emery, the former chief source of supply. Though the employment of substitutes and the increase of imports in 1918 reduced the demand for the domestic abrasives the output was many times that of normal years before the war.

Montana Section of the A. I. M. & M. E.

By OLIVER E. JAGER

The Montana section of the Institute took advantage of the presence of James F. Kemp and Charles K. Leith, who are on a professional visit to Butte, to hold a special meeting at the Silver Bow Club on the evening of May 2. The meeting was a representative gathering, numbering about 100, including many ladies. The proceedings opened with a dinner, after which the chairman, Frederick Laist, introduced Professor Kemp.

He said that, as the new president of the Institute was a prominent mining geologist, he hoped that more geology would appear in the Transactions. Butte was always well to the fore with contributions of this nature. He went on to show how geologic history resembled human history. There was a placid period followed by an upheaval, of which the last four years had furnished us a good example. We had now to face a period of reconstruction. The metal markets were dull, and yet men had to be got back to work. Such problems appeal to engineers, and the present one would give ample opportunity for constructive thinking. The army life was good for a man in some ways. It was healthy; it taught discipline and respect for authority; but it must be remembered that having everything arranged for a man was bad for his mentality and for his initiative. This fact must be kept in mind when handling returned soldiers. The soldier felt that he had made a sacrifice, and that the sacrifice demanded recognition in the shape of better conditions. On the other hand, there was still a lot of virtue in the old idea of "a good day's work for a good day's pay." The United States is less affected by the War than any other country, but we have an enormous debt. It was an engineer's war, and the reconstruction is even more a work for engineers. We have seen what Kultur meant—absolute selfishness on the part of one nation. This philosophy was now exploded. In the reconstruction we shall need the idealism of Josiah Royce, tempered by the pragmatism of William James. Even if we cannot evolve a perfect set of conditions at first, let us, at least, set up some ideals and see how they work, or why they don't work.

The next speaker was Mr. Leith. He showed how international relations were bound up with mineral problems. His speech was also instructive in showing how the lack of information was hampering the Peace Conference. It was not the fault of the Conference that it has moved so slowly; it could not move any faster on account of the magnitude of the problems involved, and of their far-reaching and interacting effects. Mr. Leith stated that one-third the world's minerals moved between international boundaries. The War had shown how little we really knew of mineral deposits, especially with respect to their geographic positions. The speaker had first realized the importance of minerals in international relations when he was employed on the Shipping Board, which was cutting down shipping space to make room for troops. This Board was working in conjunction with the War Industries Board and the War Trade Board. Information on many problems was hard to get, such as, for instance, on the complete movements of copper, including the final destination of the metal, especially with reference to Germany. Data of the kind required were non-existent, as they had never before been needed. Engineers from all parts were called in to help, and the big corporations assisted in every way. By the time the Armistice was signed a world balance-sheet had been prepared of all the great commodities, showing consumption, routes followed, tonnages, and other main facts. The result of this work was a shifting of interests in the mineral industry. The production of some minerals was stimulated, of others was discouraged. Mineral questions being expected at the Peace Conference, especially in reference to embargoes and indemnities, he went to Paris with his data. There he saw the mineral question in its international aspect. The American army had begun an independent appraisal of the war damages; 350 engineers were assembled to assess the amount of the devastations. The speaker helped to correlate the reports of these men on the damage to mineral industries. The damage to the coalfields of Northern France was as severe as had been reported, though a certain amount of coal will be produced in the near future. The methods of appraisal used by the French were different from those used by the Americans, but misunderstanding had given way to mutual appreciation. The destruction of the Belgian blast-furnaces and zinc-works developed an interesting problem. Supposing these zinc-works to be replaced, what about the ore-supply to operate them? Zinc ore from Broken Hill used to go to Belgium. It will now be deflected to England for some time to come. This fact was kept in mind when appraising the damage, and goes to show how complicated the whole affair was. Damage to the iron mines of Briey was not so great, as the Germans occupied them till the last moment, and did not have time to wreck them. The amount of ore extracted was not as great as was supposed. The open-pit mines of Lorraine were more energetically worked. In considering the indemnity that Germany should pay, many mineral questions came in. It was thought desirable to assess the value of the ore deposits in Alsace Lorraine, as it might be desired to allow this value to figure as part of the indemnity, a parallel case being in 1870, when Germany allowed France to subtract the value of the railroads taken from her. In Alsace there are potash deposits which were mined by the Germans. The French are making big plans to develop these deposits, so as to be independent of Stassfurt. In all this estimating, the values estimated by various engineers varied over a tremendous range—up to 3000% in some cases. The German colonies also have mineral deposits. These had to be valued in order to complete the information necessary to show whether these colonies should be considered as assets or as liabilities. Some were found to be in the latter class. Mineral problems also complicated the boundary questions. By moving a boundary a valuable mineral deposit might change its nationality, as in Poland. There was hardly a boundary question that did not involve a mineral deposit. Another group of questions involving minerals was that of embargoes, and how the excess of any mineral should be disposed of. Many embargoes have been established. The French have shut out practically all foreign materials, including minerals. England is not quite so drastic. but has developed a system of licenses to regulate imports. Many other nations had embargo problems. It was difficult to get the information necessary for solving such problems, as the information obtainable was of a local character only. These local information-sheets had to be combined to form data of international character. Till the world is readjusted to approximately normal trade conditions, these problems will come up. The Peace Conference is trying to settle things with the machinery at hand, but that machinery is inadequate. The far-reaching nature of the various problems calls for information of such gigantic scope as to be unobtainable under present conditions. More than half the time of the delegates in Paris was spent on these commercial problems. The French view the League of Nations plan from a material or commercial aspect, while England is partly ideal and partly practical. An international economic commission is in process of formation. This will consider general economic problems as they affect various countries. The degree of economic control that the Allied countries can exert will determine largely what indemnity Germany can pay. Minerals have been proposed as part of the indemnity; for example, Germany is to supply so many tons of coal per annum; but the problem has too many variables to be easily solved. The questions now before the Peace Conference are new and great, too great, in fact, for the present machinery to handle, so the men considering them are looking for guidance. He suggested that the engineers of this country should study the situation so as to be able to supply some of the information required. Some work is already being done to get this information. He thought that the technical journals could help.

Mrs. Kemp, who accompanied her husband in order to take the opportunity of urging on the Butte ladies the formation of a local section of the Woman' Auxiliary, was next introduced. She made a short but interesting speech in which she told how, when the United States entered the War, the women relatives of the members of the A. I. M. & M. E. got together to help the men who were going overseas. They raised money and clothing; they knitted; they adopted orphans, and did Red Cross work. She went on to describe the organization, and how it is governed. Now that there was no more need of war work, whither should their energies be directed? The answer was still the same: "help the men"; but help them at home, in the mines and in the smelters. There was plenty to do. Primarily they should combat ignorance. Till labor felt the need of capital as capital feels the need of labor, there would always be trouble. In this country eight and a half million persons over 10 years of age cannot read English, and five and a half million of these cannot read any language. Education must Americanize these illiterates, or they will some day be voting without knowing what they vote about. They must be taught to read a newspaper, and they must be taught our traditions, so that they eventually become part of us. The speaker thought that the women could get at the women-folk of these illiterates and so reach the children. She advocated the teaching of sewing and cookery as a means to this end. While these foreigners read a foreign language only, they may be molded to any form—mostly I. W. W.—by malcontents of their own race. Mrs. Kemp said that she hoped a Section of the Woman's Auxiliary would be formed at Butte, as there was a good field for such work. A meeting would be held on May 8 to consider the matter. There was already a Section at Anaconda. A local Section should be a valuable assistance to the men in their work. In regard to education, the night-school was doing well. She had visited the school that afternoon and was favorably impressed with what was being done.

W. E. Maddock, City Superintendent of Schools, was called on for a few words about the night-school. He said that it was organized last January to teach foreigners English, and the traditions and history of the United States. This had been attempted two years ago, but was postponed for legal reasons. This difficulty was now overcome, and the school was flourishing with an enrollment of 530, of whom 110 were women. Many had since left through unemployment, but very few—practically none—left the school for any other reason. The work was handled in three sessions, partly in the daytime and partly at night. The speaker described the work as fascinating, and stated that the pupils were earnest and enthusiastic. The movement could be written down a success. They had an exceedingly efficient corps of teachers, mostly from the public schools, who had been chosen on account of special qualifications for this work.

The Chairman made a few concluding remarks emphasizing the need of such education, and quoted an instance, that had lately come to his knowledge, of a letter in the Serbian language which was putting forward pernicious doctrines calculated to impress the ignorant.

The meeting was followed by informal conversation, the character of which indicated keen interest in the matters that had been discussed.

REVIEW OF MINING

HOUGHTON, MICHIGAN

FURTHER CURTAILMENT.—MINE INSPECTORS MEET.

Depression in the copper industry is marked in the Lake Superior district. More companies contemplate suspension, and others on further curtailment. Such properties as the Mass Consolidated, Victoria, and White Pine in Ontonagon county, continue to operate. They are running at a loss, and while their total output of copper makes no great difference to the surplus on hand it does require a continuous and sustained drain on their treasuries, so that eventually they will have to shut-down.

Mine inspectors from every mining county in northern Michigan and safety-first experts representing every copper and iron property in the peninsula met at Houghton on April 23, 24, and 25. The meeting was arranged by B. C. Pickard of the U. S. Bureau of Mines and by F. W. Sperr, professor of mining in the Michigan College of Mines. This was the first meeting of mine inspectors ever held. The program was of great practical benefit.

LEAD, SOUTH DAKOTA

MINERAL PRODUCTION OF THE STATE DURING 1918.

According to the annual report of the State Mine Inspector, O. Ellermann, the production of gold and silver in the past year showed a decrease of $814,860 over the previous year's output. The total for 1918 was as follows:

Mine	Tons	Value
Homestake	1,628,630	$5,923,653
Trojan	107,373	530,642
Mogul-Ofer	33,750	169,975
Golden Reward	6,542	36,589
Bismarck	5,120	18,864
Miscellaneous	235	5,300
Placer	....	1,400
Total	1,781,650	$6,686,423

The shortage of labor was directly responsible for the decrease. The Golden Reward suspended operations in April. In addition to the above, the Homestake shipped tungsten ore (wolframite) valued at $281,475. The Bismarck received $2282 for ores of this class; and lessees and smaller producers received $3550, making a total tungsten production of $287,307. Of mica, 249 tons was shipped to market, valued at $10,464; 1500 tons of lithia ore, worth $82,500; 641 tons of copper ore, mostly from the Maloney Blue Lead Copper Co. near Keystone, valued at $9157; 159 tons of lead-silver ore and concentrate, valued at $6521; 916 tons of pyrite, worth $7200, from the Olaf Seim mine near Deadwood; gypsum, $45,160; coal, $39,237; kaolinite, $8000; beryl, $270; columbite, $280; and limestone and structural materials, $180,000; making the grand total for all mineral production of $7,362,520.

An average of 2049 persons was employed by the industry excluding coal mine and quarry employees. There were no fatalities.

DOUGLAS, ARIZONA

EPIDEMIC AT HILL TOP SUSPENDS WORK.—PATAGONIA AND COURTLAND DISTRICTS ACTIVITIES.—LABOR AND HIGHWAY CONSTRUCTION.

After a siege of several weeks, influenza has been routed at the Hill Top and Hill Top Extension mines in the Chiricahua mountains, and doctors and nurses who went from Douglas have returned here. Out of 50 cases at the Hill Top but two deaths occurred. However, the effect on the property was disastrous, as all work was suspended during the epidemic. R. O. Fife, the manager, decided that this was the best course. The clubhouse built recently by the company was transformed into a hospital and several miners were appointed orderlies. At the Extension, the manager, John Blumberg, was also forced to close the mine. No deaths have been reported from there. The Hill Top is a lead-silver mine, being developed by tunnels extending entirely through the mountains. A large body of ore has been opened. The owners are Kansas City people. About 75 men are employed.

One of the most important strikes known in the Patagonia district of Santa Cruz county was made recently at the Mowry mine, according to arrivals here. A new lens of high-grade silver ore has been cross-cut for more than 20 ft. and was still in rich ore when our informant left Patagonia. The ore occurs both as carbonates and sulphides. The latter is being shipped to El Paso. High-grade manganese is also being mined from a lease on the same property.

The labor surplus in the Warren district and at Douglas is said not to be showing any great increase, and steps are being taken promising to offer relief in the near future. The State Engineer, Tom Maddock, following an inspection of roadwork under way in Cochise county, stated that he intended recommending the expenditure of large sums of Federal aid funds on highways, spending dollar for dollar with the county on designated roads. At a meeting of prominent men from all parts of the county, held at Douglas on April 19, it was recommended that the Board of Supervisors call an election for a bond-issue of $1,000,000 to complete the highway system of the county. This is expected to be acted upon favorably by the Supervisors, who were instrumental in calling the meeting, as they desired to learn public sentiment in the matter.

Courtland, 45 miles north-west of Douglas, although a copper camp and somewhat neglected during the boom days of the industry, has shown increased activity with the fall in the price of the metal. The Great Western company, the largest operator, is developing a body of high-grade sulphide ore in its new shaft. The working-force is being increased gradually.

The lease of O. T. Smith, O. J. Smith, and Robert McKay of Johnson, on the Leadville Mining Co.'s property, includes the Freak claim and most of the original Leadville ground lying next to the Musso property. The lessees propose to sink a 200-ft. shaft, and then drive toward the Musso property to cut the extension of a high-grade orebody opened in the Musso. A 25-hp. gasoline engine has been installed. A 10 by 12-in. air-compressor is to be put in to drive drills and other machinery. Smith brothers and McKay also have leased No. 2 shaft of the Leadville company, including about 600 acres. On the 400-ft. level of this shaft considerable ore has been blocked out. Shipments are to be made at once to the Calumet & Arizona smelter at Douglas. Exploration will be the main endeavor for the present. By the fall it is believed that there will be 75 men employed. The lease operated by Peter Musso, also on part of the ground of the Leadville company, recently opened ore carrying over 8% copper, with gold and silver sufficient to pay transportation and smelting charges. Two carloads sent to Douglas recently are said to have netted more than $1000 each. Shipments are being made regularly.

TORONTO, ONTARIO

LEGISLATURE PASSES NEW MINING REGULATION.

An act amending the mining laws of the Province has been passed by the Ontario Legislature, making some important changes in the provisions to secure the safety and health of mine-workers. The extensive scale on which mining is now conducted, and the greater depth of mines, rendered the former rules as to precautions for safety entirely inadequate. The provisions now adopted are much more stringent and specific, especially regarding hoisting, providing for frequent inspections of the ropes and equipment, and the testing of the safety appliances under load conditions. The rules governing the use of electricity are based on those adopted by the U. S. Bureau of Standards. New and more detailed regulations regarding blast-furnaces are also embodied in the Act. Before it was placed on the statute book, both mine managers and labor organizations were consulted as to its provisions, which are understood to have been generally approved by all interested.

MONTERREY, MEXICO

METAL PRODUCTION AND MINES IN THE REPUBLIC.

Interesting statistics regarding the operation of mines in Mexico during 1918 are contained in a statement just issued by Leopoldo Lopez, chief of the Bureau of Mines of the Department of Industry and Commerce. The production figures cover only the first nine months of the year.

Metal	Kilogrammes	Value
Silver	1,601,331	P05,054,571
Gold	6,185	3,244,881
Lead	79,335,629	23,800,089
Copper	55,080,286	06,090,344
Zinc	16,135,131	9,036,223
Antimony	2,208,121	2,471,147
Arsenic	901,512	....
Tin	13,537	24,638
Mercury	120,000	785,297
Tungsten	109,419	787,274
Graphite	4,178,686	668,589
Manganese	1,889,082	458,321
Molybdenite	23,761	36,038
Total		P180,064,983

The total number of concessions in each State, and the additional number granted during 1918 follows:

State	Mines	Concessions in 1918
Aguascalientes	2,671	11
Lower California	827	28
Coahuila	814	74
Chihuahua	4,858	250
Durango	3,835	220
Guanajuato	1,233	155
Guerrero	1,024	34
Hidalgo	1,300	180
Jalisco	1,802	80
Mexico	853	4
Michoacan	632	37
Nuevo Leon	1,092	131
Oaxaca	1,610	63
Puebla	259	31
Queretaro	165	34
San Luis Potosi	707	79
Sinaloa	1,600	135
Sonora	5,090	489
Tamaulipas	147	11
Vera Cruz	67	7
Zacatecas	2,146	219
Miscellaneous	453	18
Total	33,186	2,289

The area of all claims is 1,183,437 acres, a gain of 53,357 during 1918.

TELLURIDE, COLORADO

MINING RARE MINERALS IN PARADOX VALLEY.

The comparatively newly discovered rare-mineral fields of Paradox valley are developing into an important mining region. The output of vanadium and carnotite ores has been considerable, and capital is now taking an interest in this part of the State. The only handicap to rapid development is the lack of good transportation, as the fields are at some distance from rail, and roads are in poor condition. The Primos Chemical Co. is building a larger mill to replace the 100-ton one lost by fire.

The Colorado Vanadium Co. is increasing production and is shipping ore at the rate of 30 tons per day.

The Standard Chemical Co. resumed milling on April 1 and is gradually working up to full capacity.

The W. L. Cummings Chemical Co. plans extensive development of its carnotite claims in lower San Miguel and Montrose counties. O. B. Willmarth, the rare-metal expert of Montrose, has been appointed local manager.

THE MINING SUMMARY

ALASKA

Juneau.—Alaska Gastineau in April treated 167,630 tons of ore averaging 81.3 cents per ton The recovery was 78.47%. In March, 183,550 tons was treated A year ago the quantity was 125,135 tons, assaying $1.148 per ton

ARIZONA

Ajo.—New Cornelia had to suspend leaching ore last week on account of a fire at the pumping station at the main well of the water-supply system. Water was brought in by rail from Gila Bend for a while.

Kingman.—L. R. Myers and associates of Minneapolis have taken over the Middle Golconda mines and have consolidated it with the Golconda and O'Dea properties as the Highland Mining Co. A tunnel is to be driven from below Layne Springs in Todd basin to cut the veins of the Middle Golconda and Golconda at a depth of about 1000 ft. A mill is contemplated on completion of the tunnel, there being plenty of water available.

Morenci.—The old Stargo silver mine is to be re-opened by G. A. Stoneman, W. B. Harmony, C. B. Beach, and E. W. Baum of Phoenix. Previous work was to a depth of 1400 feet.

A syndicate of Arizonan men has taken over the 26 claims of the Stargo Silver Belt Mining Co. A large quantity of silver ore has been shipped from the property in the past.

Oatman.—The United Eastern company pays 7 cents per share, $95,410, on May 28. This brings the total to $1,676,490, $422,530 of which was paid in 1919.

Prescott.—The 1600-ft. tunnel of the Black Canyon Mining Co. on Turkey creek has opened a 4-ft. vein assaying 25 oz. of silver per ton. The high-grade ore is being stacked in preparation for shipments. A mill is planned for the near future.

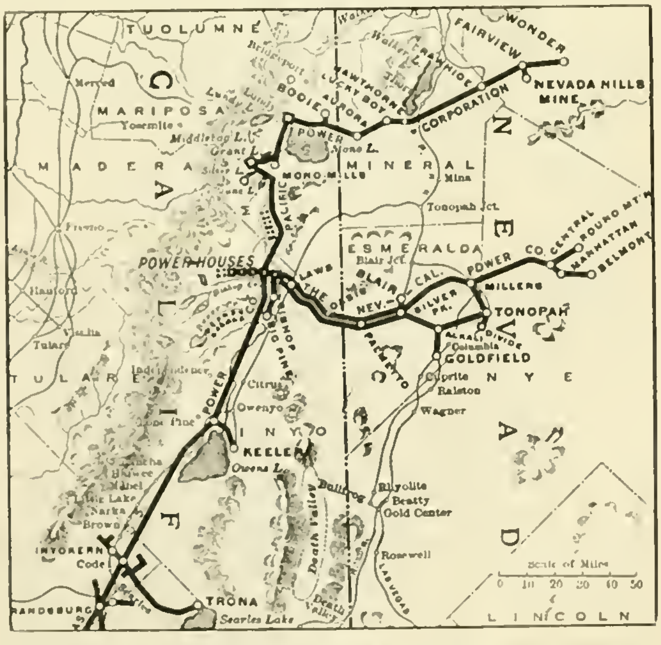
Tucson.—The Mineral Hill Consolidated Copper Co., in the San Xavier district, is to erect a large mill. Ore that was opened some time ago on the 340-ft. level has now been developed on the 600-ft. level. U. A. Fritschie is manager.

CALIFORNIA

Alleghany.—The El Dorado-Wisconsin Mining & Milling Co. has filed articles of incorporation with the Secretary of State at Carson, Nevada, with T. J. Flynn as president. The company has acquired the El Dorado, El Dorado Extension, and Gold Bullion claims in the Alleghany district of Sierra county. The property is equipped with a 10-stamp mill, compressor, and is operated by electric power. The mine has produced several hundred thousand dollars of gold above the present tunnel-level, from which a shaft is to be sunk.

Cerro Gordo.—The report of the Cerro Gordo Mines Co., operating in Inyo county, contains the following information: L. D. Gordon is general manager, J. C. Climo is superintendent, H. G. Rose is in charge of the mine office, and J. W. Reno is purchasing agent. Earnings in 1918 amounted to $126,794 from ore sold, plus settlements of $11,696 from 1917, sale of bonds, and cash $79,699, making a total revenue of $233,188. The cost of operation was $147,895, bonds $23,000, taxes $10,453, and No. 6 dividend $50,000, totaling $231,348. The cash balance at the end of December was $1840. Current assets total $138,005, and liabilities $8316. Development amounted to 4603 ft., costing $12.63 per foot. Production came mainly from the Newtown slope 1500 ft. north of the shaft. Driving on this vein at 700 ft. is under way, and while no ore-shoot has been found, pockets are, and possibilities are favorable. The Jefferson orebody was cut off by a fault above the 900-ft. level in 1917, and 500 ft. of exploration has failed to find it, and the search has been stopped. The output was 619 tons of zinc ore, carrying from 24.3 to 40.1%; 2166 tons of silver-lead ore, averaging 23.12 oz. silver, 21.4% lead, and 0.015 oz. gold; and 9389 tons of old slag, assaying 2.92 oz. silver and 12.27% lead. To treat the low-grade ores in the mine, an agreement was made with H. R. Layng of San Francisco to erect a mill on terms favorable to the company. A letter from Mr. Layng on April 5, 1919, states that he found concentration and flotation to give a recovery of 73% of the silver, 85% of the lead, and 28% of the zinc; but the concentrate was low-grade and excessive in zinc. A combination of concentration and volatilization is now being tried. On a basis of 50 tons daily of 7% lead and 8-oz. silver ore, the treatment cost would be $4.26 per ton, this including freight to market. If all goes well, a plant should be started at the Keeler by August, and be ready by November next.

Bishop.—The Nevada-California Electric Corporation, which has power-houses on Bishop creek, proposed plants on Baker creek, connections with lines to the extreme south



PART OF CALIFORNIA AND NEVADA, SHOWING MAIN TRANSMISSION-LINES OF THE NEVADA-CALIFORNIA ELECTRIC CORPORATION SUPPLYING MINING DISTRICTS of California, and supplies current to the principal mining districts in Nevada, shows the following results for 1918, in comparison with the two previous years, according to the 'Commercial and Financial Chronicle' of New York:

	1918	1917	1916
Earnings from all sources	$2,158,706	$1,997,969	$1,550,775
Expenses	1,036,452	919,878	612,738
Operating profit	$1,122,254	$1,078,091	$938,037
Interest charge	635,611	549,775	463,585
Depreciation	118,553	121,318	95,370
Net earnings	$368,091	$406,998	$379,082
Adjustments to profit and loss	dr. 12,158	cr 29,906	dr. 4,951
Discount on securities sold	dr. 50,199	dr. 17,331	dr. 9,407
Surplus	$305,734	$419,571	$364,724
Dividends	318,271	352,006	265,849
Net change in surplus	−$12,537	+$67,565	+$98,875

Crescent Mills.—The Crescent mine of the Philadelphia Exploration Co., closed since last August, has been reopened. A. MacDonald of Boulder, Colorado, is the new superintendent; George Worthington, of the same place, is foreman; and Herbert Whiting of Quincy, California, is assayer.

Hutton.—At the Blue Ledge copper mine, in the Elliott district of Siskiyou county, near the Oregon border, the winter's accumulation of 1000 tons of sulphide ore is now being moved over the Rogue River Valley Railway and Southern Pacific at Medford, Oregon. The 34-mile haul by teams and trucks costs $10 per ton. Twenty-seven miles of standard crushed rock highway, extending to the California State line, is to be completed by the State of Oregon at a cost of $50,000. A moderate reduction in transportation costs will render available for shipment several hundred thousand tons of developed ore. Gold and silver are important metals in this ore. This district includes the Gray Eagle mines at Happy Camp, and is one of the most promising copper areas in California.

Kennett.—At the Mammoth smelter the boilermakers, machinists, electricians, and railroad men—30 in all—have demanded an increase of 50 cents per day, and a half-holiday each week. Wages at present are: machinists and boiler-makers, $5.72; electricians, $5.32; brakemen, $4.44; locomotive engineers, $5.72; firemen, $4.28; and conductors, $5.28 per 8-hour shift. According to the general manager, George Metcalf, the company is employing 600 men; but only development is being done in the Mammoth mine, while the works are smelting ore from the Balaklala mine. The mechanics went out on strike on May 12. The smelter will continue to work as long as possible.

Marigold.—The Marysville Dredging Co. lost a boat on May 10, fire starting in the transformers spreading all over the dredge. The hull was of wood, and had been operated for 8 years.

Plymouth.—The Plymouth mine in March produced 11,900 tons of ore yielding gold valued at $61,000. Operations cost $34,000, and development $10,000, leaving a profit of $17,000. On the 2450-ft. level a raise at 274 ft. north was driven 23 ft. in ore assaying $9.40 per ton across 48 inches.

San Francisco.—Details of every oilfield operation in California during the past fiscal year is briefly given in the third Annual Report of State Oil and Gas Supervisor, R. P. McLaughlin. The report has just been received from the State Printer, and copies may be obtained by addressing the State Mineralogist, Fletcher Hamilton, Ferry building, San Francisco; or by personal application to any of the branch offices of the Bureau. Besides the complete list giving the status of every well for which notice was filed with the Supervisor, the report sets forth the general conditions of all the oilfields during the year ending June 30, 1918, such as distribution of ownership of proved oil-land and statistics of production by various fields.

COLORADO

Breckenridge.—The annual report of the Tonopah Mining Co. of Nevada, which controls the Tonopah Placers Co., operating three dredges near Breckenridge, contains the following: During 1918 the gross value of gold recovered was $282,974, but operations cost $332,902, leaving a loss of $49,928, reduced to $39,923 by sundry credits. The boats dug 3,267,307 cu. yd., averaging 8.6 cents per yard The yield was 13,565 oz. of gold and 3345 oz. of silver.

Cripple Creek.—Gold output of this district in April was $674,715. Dividends totaled $242,000.

The Granite company is to put in a 175-hp. electric compressor at its Dillon shaft, which will become the main operating point. This shaft is 1700 ft. deep. The compressor is being moved from the Nicholls shaft of the El Paso.

The Vindicator's quarterly report states that 6781 tons of ore was shipped on company account and 4069 for lessees, from which net earnings were $100,000. There is a shortage of helpers underground.

Telluride.—In the Belmont Wagner Mining Co.'s report for the 10 months ended December 31, 1918, the following appears, written on March 1, 1919:

Preliminary work in the mine, a new crushing-plant at the St. Louis tunnel, a new aerial tram from this plant to the mill, remodeling of the old mill, a new compressor, quarters, shops, etc., were all completed and the mill started in July; but owing to labor conditions and influenza, work had to be suspended in November. During 121 days the plant operated only 22.3% of the possible time. Resumption was expected early in May of 1919. J. M. Fox is superintendent and H. F. Hillard is in charge of the mill.

MONTANA

Anaconda.—The new 525-ft. stack at the Washoe Reduction Works was connected with the furnaces on May 5 Ten of the Cottrell electric precipitators are in operation. and the remaining fifteen will be ready in six weeks. Until then the old stack will carry part of the smoke.

Butte.—The North Butte Mining Co. in 1918 made a profit of $278,545, compared with $641,126 in 1917. $2,479,595 in 1916. and $1,127,646 in 1915. Dividends were $430,000, against $1,075,000 in the previous year. The output was 20,680,695 lb. of copper, 891,157 oz. of silver, and 1375 oz. of gold, 6,000,000 lb. more than in 1917, but 4,000,000 lb. less than in 1916. The cost rose to 20.91 cents per pound from 17.35c., 15.57c., 13.12c., and 11.50c. for previous years.

The extensive development that has been carried on by the Anaconda company during the past year on the Bonanza group at the foot of Excelsior avenue has proved disappointing, and the company has decided to suspend further work, according to the Anaconda 'Standard'. John Berkin was superintendent. The pumps have been moved at the Bonanza from the 1000-ft. level, and the workings will be allowed to fill to 500-ft., where the east drift will be driven farther with the hope of picking up the Star West vein, which in the earlier days was a profitable ore producer To date more than 5000 ft. of work has been done in the Bonanza, both the north vein and the Star West fissure having been cut and driven upon. The former is the 'north fork' of the Black Chief lode, which farther to the east in the Emma claim has been productive of both silver and manganese ores. The openings on both the 500 and 1000-ft. levels disclosed small streaks of silver-zinc ores with some pink manganese, but no deposits of commercial size or quality.

The south-eastern section has proved a disappointment to several large undertakings. The Butte & Superior company several months ago suspended work on a large group lying farther to the west on the Germania group of veins, after expending a large sum. Farther west and northerly, work on the Orphan Girl is reported to have resulted better and a deposit has recently started production for the Anaconda company. William Creden during the past year expended a large sum in development on a group lying between the Germania and the Bonanza groups, which also was disappointing. Both the Bonanza group and the Germania operations were carried on under working options, and the properties revert to the owners.

Three men were killed at the Rarus mine on May 2. The brakes refused to work, and before the hoist could be stopped the cages were drawn into the sheaves.

Troy.—Activity in this district is increasing, the present operators being the Snowstorm, producing 6000 tons of ore monthly, the Rambler, Iron Mask, Federal, and Liberty, all on silver-lead-zinc ore.

NEVADA

Divide.—The Belcher Divide, Belcher Extension, and Victory Divide properties have been optioned to George Wingfield and New York people.

Reserves in the Tonopah Divide mine are stated to be over 415,000 tons averaging $35 per ton.

Field.—From February 15 to April 1 the Goldfield Development Co. shipped 1090 tons of ore valued at $21,246, according to A. I. D'Arcy, the general manager. Shipments were made during this period by the company and lessees. Expenses were heavy, owing to preparations for mining on a large scale; but the returns were profitable. The report for April, which should be ready on May 15, will show a great increase in the gross value of ore shipped, as one carload worth $8600 was sent out during that month, and a number of other good lots were made. This ore was extracted by lessees in the Combination mine. Construction of a 500-ton ore-bin has been started at the shaft in Combination Fraction ground, which will be made the main working shaft of the Development company for hoisting ore from the Combination. The tonnage in the Red Top is estimated at 200,000, assaying from $7 to $8 per ton. The Red Top is being prepared for production, and sampling continues there and in the Combination.

The Florence Divide Mining Co., owning claims in the Divide district, has purchased the Witt-Brandon-Taylor-Mechlin lease on the Red King claim of the Florence Goldfield for $60,000, partly in cash and partly in shares of the Florence Divide. The lease will expire on January 1, 1920. The last four carloads of ore shipped averaged $60 per ton.

Klondyke.—The boom at Divide has spread to this old district, in that attention is being given to several deposits by newly-organized companies.

Pioche.—The Combined Metals Co. is to raise the sum of $300,000, to be spent on a treatment plant. According to the manager, E. S. Snyder of Salt Lake City, there is 150,000 tons of ore averaging 0.043 oz. gold, 8.26 oz. silver, 8.27% lead, and 18.15% zinc developed. Ore already marketed was worth $392,113, of which $142,803 was net from smelters. Workings in the mine total 4350 feet.

Tuscarora.—C. C. Griggs has been appointed general manager for the Holden Mining & Milling Co., owning mines in this district. Preparations are being made for resumption of work on a broad scale. Mr. Griggs is manager for the Stewart and Nabob Con. mines at Kellogg, Idaho.

Wonder.—The Nevada Wonder company pays 5 cents per share, $70,420, on May 21. The total is $1,549,002.

Yerington.—The Nevada-Douglas company's balance-sheet at January 31, 1919, shows current assets amounting to $478,987, of which $387,108 is copper in transit; while liabilities total $551,910, of which $151,554 is A. S. & R. Co. advances, $182,818 for Mason Valley company charges, and $134,923 for accounts and wages unpaid.

OKLAHOMA

Picher.—The Tri-State Safety and Sanitation Association will probably become the Tri-State chapter of the American Zinc Institute. Membership consists of mine operators and dealers in mine supplies. C. F. Dike is president and W. B. Shackelford is secretary.

SOUTH DAKOTA

Lead.—The roof of the old Ferris stope on the 100-ft level of the Homestake mine collapsed last week, taking down with it two cars of drill-steel and a new drill-sharpening machine ready to be erected in the shop on the surface. The cave-in is 40 ft. across and 20 ft. deep.

The annual report of the Homestake Mining Co. for 1918 shows the following results, according to B. C. Yates, the superintendent:

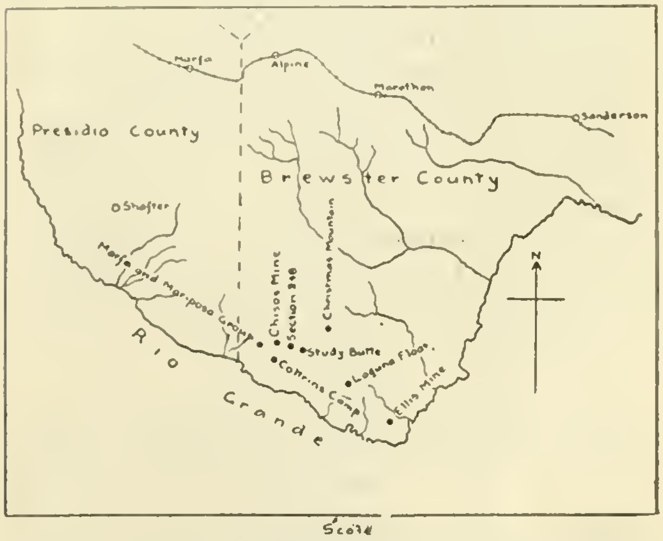
A shortage of labor curtailed operations in every department. A total of 7354 ft. of development work was done. There are 1,716,418 tons of ore broken in stopes, and there is enough ore developed for many years of profitable operation. Two hoists and a 3000-cu. ft. compressor were changed to electric drive. One fan unit of the mine-ventilating system was erected, and another is being put in. A coal-storage bin of 7000-ton capacity was built. Wolframite sufficient to keep the special mill at work continually was mined, and a considerable tonnage remains.

The mills treated 1,628,630 tons of ore, yielding $3.633 per ton, a total of $5,916,890. Wolframite sold realized $167,468. With sundries, the total income was $6,121,347. Mining charges were $2,441,873; tramway operation, $46,793; milling, $510,113; re-grinding, $28,395; cyanidation, $387,982; Ellison coal plant, $107,050; Spearfish hydro-electric plant No. 2, $121,894; compensation and sociological, $141,774; general, office, salaries, legal, etc., $201,873; and taxes, $349,159. The total expenditure was $4,399,198, equal to $2.70 per ton. Dividends totaled $1,506,960. The net profit was $215,189. At the end of 1917 the excess of current assets over liabilities was $1,569,314, and at the end of 1918, $1,778,530.

TEXAS

Austin.—Two interesting bulletins have recently been issued by the University of Texas here: No. 1818 is on the geology of Dallas county, by E. W. Shuler; while No. 1822 discusses the anticlinal theory as applied to some quicksilver deposits in the Terlingua district, by J. A. Udden.

Wichita Falls.—A directory being prepared of oil com-



SKETCH-MAP OF QUICKSILVER DISTRICTS OF TEXAS panies in this district so far contains the names of 762, with a capital of $38,100,000. Of these, only 70 have paid dividends, which total $5,468,659.

UTAH

Eureka.—The Ridge & Valley Mining Co. last year produced ore sold for $141,721. The net profit was $4240.

On May 9, miners in this district decided to demand an increase of 75 cents per day, abolition of the rustling-card system, an 8-hour shift, and guarantees against discrimination by employers on account of organization affiliations of miners. These demands were decided upon at a meeting of 100 miners of the Tintic district held on the above date.

Park City.—All mines here were closed on May 6, the result of miners demanding $5.50 per day, a six-hour shift, and that two men be employed on all machine-drills. Wages were reduced by 75 cents on March 1, to the present rate of $4.50 for miners and $4 for helpers. About 1000 men are affected. The Judge company employs 400, Silver King Coalition 280, and Silver King Consolidated 90. One of the most serious results will be the flooding of the Ontario Silver mine. The Department of Labor has appointed Hywell Davies to investigate the trouble.

CANADA

British Columbia

Anyox.—In the Dolly Varden mines, railway, and Taylor Engineering Co. tangle, it is now stated that S. S. Taylor, on behalf of the creditors of the Taylor company, has offered $1,100,000 for the mines near Alice arm, there to be no commission. This price is $200,000 more than the sum offered the Dolly Varden Mines Co. by the Temiskaming Mining Co. of Cobalt, Ontario, its price of $900,000 including a commission of $50,000, provided the railway received a renewal of charter from the Provincial government.

Greenwood.—It is possible that the Greenwood smelter, recently closed by the Canada Copper Corporation, will be re-opened, as the company has offered the plant and contiguous properties to the citizens of Greenwood for the sum of $125,000. As the existence of the town depends upon the maintenance of mining, and as the company's proposal is considered reasonable, it is very probable that it will be accepted. At Boundary Falls is the New Dominion smelter, which has been idle for some years. This also has been offered to the Greenwood people, together with its mines, on favorable terms. The smelter at Greenwood is intact and ready to be blown-in at any time. Oscar Lachmund, metallurgical engineer, has been retained by the Greenwood committee in an advisory capacity.

Nelson.—Eastern British Columbia is to have an International Mining Convention here on June 19, 20, and 21. E. W. Widdowson, provincial assayer, is treasurer.

Phoenix.—There has been an immense cave-in in the workings of the Granby mine here. No serious damage, however, is reported, as the collapse was not altogether unexpected.

Trail.—The Consolidated Mining & Smelting Co. has reduced wages by 50 cents per day for copper miners and 25 cents for smelter-men. The minimum is $3.50 per shift. The company has reduced treatment charges on ore from $8.30 to $7.85 per ton, effective April 12.

Yukon

Dawson.—The ice on the river here broke on May 10. No damage was done, as was the case in 1918.

MEXICO

Cananea.—Bandits raided this place on May 9, robbing the bank of $20,000 and supplies from stores. They then headed south. Five were captured and executed.

PERSONAL

Note. The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

C. N. Lakenan is in New York.

F. F. Sharpless is in Sonora, Mexico.

R. E. McConnell has returned from Germany to Los Angeles.

Charles A. Burdick has moved to 120 Broadway, New York.

Robert E. Kinzie has returned from the west coast of Mexico.

Robert Musgrave sailed from Victoria, B. C., for Shanghai on the 9th instant.

Deane P. Mitchell passed through San Francisco on his return from Siberia to London.

Edwin J. Collins of Duluth is in Arizona on a two weeks examination trip to the Ray district.

T. J. Jones sails from San Francisco for Vladivostok on his way to Kyshtim, Siberia, on May 29.

L. V. Bender, superintendent of the Washoe plant at Anaconda, is on a trip of inspection in the Southwest.

G. B. Holderer is in Cuba on professional business with headquarters in the Horter building, Habana.

A. H. Hubbell, of the editorial staff of the 'Engineering and Mining Journal', is visiting Western mining centres.

Charles Bocking, assistant manager of the Butte & Superior Mining Co., was in San Francisco during the past week.

H. C. Carlisle, superintendent for the Mandy Mining Co., operating a copper mine near Le Pas, Manitoba, is at New York.

F. W. McNair, president of the Michigan College of Mines, has been appointed consulting engineer to the U. S. Bureau of Standards.

George A. Chapman, of New York, consulting metallurgist to the Minerals Separation company, is in the Lake Superior district.

A. E. Drucker announces that he has organized the Drucker Smelting Corporation with an office at 30 Church street, New York.

Arthur S. Dwight, Major in the 11th Engineers, is expected at New York from France, where he performed distinguished service.

C. M. Weld has resigned as assistant executive to the War Minerals Investigation department of the U. S. Bureau of Mines, and will resume consulting practice in New York.

W. H. Blackburn, superintendent for the Tonopah Mining Co., returned to Nevada last week from the company's Eden gold mine in Nicaragua, where the new mill is working well.

A. W. Allen has resigned from the editorial staff of the 'Engineering and Mining Journal' to become chief engineer for the Penyon Syndicate. Mr. Allen expects to leave New York for Chile about the middle of June.

Sidney Stone, manager of the Butters' mill near Virginia City, Nevada, for nine years, died suddenly at Oakland, California, last week.

Edmundo Girault, for many years general manager for the Cia. Minera San Rafael y Anexas, Pachuca, Mexico, died on May 4. His widow and family are living at San Antonio, Texas.

The annual meeting of the American Zinc Institute will be held at St. Louis on June 9. This is a postponement from May 12. W. F. Rossman is chairman of the committee on arrangements, at the Pirece building, St. Louis.

THE METAL MARKET

METAL PRICES

San Francisco, May 13

Aluminum-dust, cents per pound	50—60
Antimony, cents per pound	8
Copper, electrolytic, cents per pound	15¾
Lead, pig, cents per pound	5¾—6¼
Platinum, per ounce	$100
Quicksilver, per flask of 75 lb	$80
Spelter, cents per pound	8
Zinc-dust, cents per pound	10—12

The report of the U. S. Bureau of Mines for April, covering the position of over 40 metals, minerals, and products, is now to hand. Excerpts will be made from this useful 54-page report. Summarizing, the report says:

"The mineral industry is still in a stage of readjustment. Markets are quiet and production is still largely curtailed. The various industries are gradually using up accumulated stocks, while the Government has been disposing of its supplies. Prices are reaching lower and more stable levels, and it is expected that conditions and production will improve. Building activity is being resumed. While prospects for foreign trade are improving and ocean rates are declining, the shortage of ocean bottoms is still acute. In the special mineral industries, such as manganese, potash, graphite, and pyrite, which have been developed during the War, activity is very limited, and many of the plants are closed. This condition will continue until it becomes evident as to what the movement and prices of foreign material will be."

EASTERN METAL MARKET

(By wire from New York)

May 13.—Copper is more active and higher. Lead is quiet but firm. Spelter is inactive but steady.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, to May 5, 1919, the United States government paid $1 per ounce for all silver purchased by it, fixing a maximum of $1.01½ on August 15, 1918. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last time being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

Copper production of some of the large mines in April was as under:

Mine	Pounds	Mine	Pounds
Anaconda	13,750,000	Miami	4,480,748
Arizona	2,400,000	Old Dominion	2,389,000
Cerro de Pasco	4,780,000	Phelps Dodge	8,262,176
East Butte	1,347,580		

Copper companies paid dividends totaling only $2,064,657 during April, compared with $4,361,644 in that month of 1917, and $7,875,834 in 1916. The first four months of each of the current and past three years show the following distribution, $25,048,986, $13,070,091, $53,252,171, and $35,020,858.

Copper surplus in this country is now estimated at 1,300,000,000 pounds.

TIN

Prices in New York, in cents per pound. The monthly averages in 1918 are nominal. On December 3 the War Industries Board fixed the price to consumers and jobbers at 72½c. f.o.b. Chicago and Eastern points, and 71½c. on the Pacific Coast. This will continue until the U. S. Steel Products Co.'s stock is consumed.

Lead ore at Joplin, Missouri, last week averaged $57 per ton, basis 80% metal. The Tri-State output was 2189 tons of concentrate.

Cost of producing lead by the Bunker Hill & Sullivan company at Kellogg, Idaho, in 1918 was 5.340 cents per pound. The average price received was 7.375 cents, for 67,125,717 pounds.

The U. S. Bureau of Mines considers that the current rate of lead production is 450,000 tons per annum, equal to 83% of the output in 1918.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Date					
Apr.	15	75.00	Apr.	29	75.00

Spelter in stock in this country approximates 40,000 tons.

Zinc ore at Joplin, Missouri, last week averaged $35 per ton, basis 60% metal. The Tri-State output was 7021 tons of blende.

Zinc in concentrate produced by Butte & Superior during April was 8,250,000 lb., also 150,000 oz. of silver.

The American Zinc, Lead & Smelting Co. reports a loss of $651 during the first quarter of 1919. The last quarter of 1918 gave a profit of $18,278, and the third period $287,207.

Zinc retorts in blast, according to the April report of the U. S. Bureau of Mines, number 90,000, compared with 165,000 at the end of 1918 and 220,000 in 1917. The greatest curtailment was in the natural-gas belt, where only 35,000 retorts are in use, against 125,000 in 1917.

Eastern Metal Market

New York, May 7.

There is little activity in any of the metals, and new features are scarce.

Antimony is firm and unchanged.

Copper demand continues light, with producers sitting tight. Quotations are virtually pegged and unchanged.

Lead is lower, and some metal has changed hands in the outside market.

Tin trading, in the market sense, is impossible.

Zinc is lifeless and prices have eased somewhat. The only buying is by dealers.

ALUMINUM

No. 1 virgin metal, 98 to 99% pure, is quoted at 31 to 33c. per pound for early delivery in wholesale lots.

ANTIMONY

The market remains unchanged at 6.62½ to 6.87½c., New York, duty paid, for wholesale lots for early delivery.

COPPER

There continues to be little domestic demand and nothing is heard about export business, except the hope that Germany and her allies will be a buyer soon after peace is signed. Present quotations are virtually pegged at 15.25c., New York, for electrolytic and 15.50c., New York, for Lake, both of which are largely nominal. Large producers hold at 15.25 to 15.37½c., with small ones at 15.12½ to 15.25c. for electrolytic for early delivery. Consumers are apparently fully covered well into May and have no incentive to enter the market, and producers see that nothing can be gained by lowering prices or pressing the market. The steel-price situation continues to act as a brake on the copper and other metal markets. That there is at least 1,500,000,000 lb. of copper above ground, with 600,000,000 lb. a normal amount, is the opinion of an authority and a leader in the industry. While present output is not over 50% of capacity, he asserts that further decided reduction is seriously needed.

IRON AND STEEL

Only mild interest is reported to be shown by steel-makers in the meeting this Thursday in New York of the Railroad Administration with the steel-makers' committee. It is hoped by some that this meeting will result in freeing the steel industry from deadly Government paltering, resulting in a probable market improvement in the end. Contraction in output and stocks is growing, and it is feared this may be overdone as in some other periods.

April pig-iron statistics of 'The Iron Age' show that 54 furnaces blew-out last month, leaving 212 active on May 1, against 372 on September 1 last year, when the peak of output was attained. The April output was 2,478,218 long tons or 82,607 tons per day, against 3,090,243 tons for the 31 days of March, or 99,685 tons per day. Production on May 1, estimating charcoal iron, was at the rate of only 28,000,000 tons per year, compared with an actual production of 39,052,000 tons in 1918.

LEAD

Because of a probable discounting by sellers of a possible reduction in the quotation of the leading interest, which is still 5c., New York, the local market experienced a decline in the past week and a part recovery. The outside market fell to 4.77½c. last Friday, with a report that 4.75c. was done. Since then the market has advanced again to 4.85c., New York, and 4.60c., St. Louis, yesterday. There is, however, little activity even at these low and probably attractive levels. Some business has been done on each day, but the prevailing feeling seems to be that while lead is cheap without doubt, buyers prefer to maintain their cash resources in a bank rather than enter the market and tie it up in lead.

At this writing the tone of the market is better. Some expect a reduction by the American Smelting & Refining Co., but there is no certainty about it.

TIN

Nothing has developed to change the situation, and the market is still under control by the Government with the price fixed at 72.50c., New York. Those who a few weeks ago felt that a free market would obtain by June 1, are now inclined to revise their guesses and say July 1. It is merely guessing, as nothing definite can be learned from those who know or should know what the future of the market is to be. It is rumored that the allocated stocks have fallen to 1500 or 2000 tons, but this is speculation also. Interest has subsided in purchases for shipment from the Far East when import restrictions are removed. Quotations for this range from 49c. for Far Eastern shipment to 49.50c. for shipment from London. There were no tin arrivals in April—the first time in many years that this has happened in any month. Spot Straits in London yesterday was quoted at £227 10s per ton, an advance of 10s. for the week.

ZINC

Consumers still refrain from the market, although it was expected they would be interested when price-levels reached 6c., St. Louis, for prime Western, which they did the middle of last week. Yesterday this grade of metal was sold to dealers at 5.92½c., St. Louis, or 6.27½c., New York, which we quote as the market. Some express the opinion that the market will fall to 5.75c., St. Louis, at which level it is expected buying by galvanizers and perhaps brass-makers will appear. Production still continues in excess of demand, especially when Government stocks are taken into consideration. There have been further shut-downs of some smelters.

ORES

Tungsten: The best grades of scheelite are quoted at $10 to $12 per unit, and those of wolframite at $7 to $9 in 60% concentrate. Lower grades are all nominal. Demand is light, and quotations are not reliable nor even definitely nominal. There is no business in ferro and no quotations are heard of.

In high-speed steel, Government re-sale stock is selling at about $1 per pound, with regular producers quoting $1.50 to $1.60 per pound.

Molybdenum: The market is quiet and quotations are nominally unchanged at 80 to 90c. per pound of MoS_2 in 90% concentrate.

Manganese-Iron Alloys: Quotations for both ferro and spiegel are unchanged at $150 and $35 to $40 per ton, delivered, respectively. Sales of carload lots of the latter have been made, some of it re-sale material. The entire market is dead. Production of ferro in April was 14,500 long tons, against 21,000 tons per month in the first quarter, and over 28,750 tons per month in 1918. The April spiegel output was under 3000 tons.

Company Reports

ALASKA GASTINEAU MINING CO.

Property: mine and reduction works near Juneau, Alaska

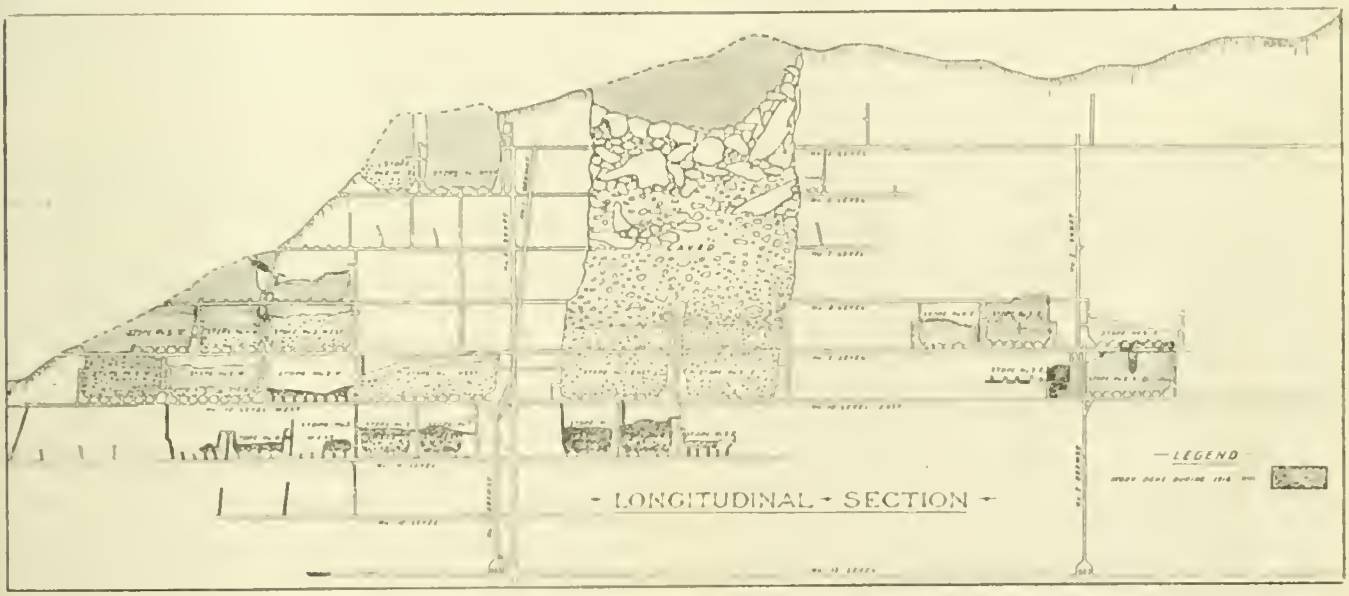
Operating Officials: G. T. Jackson, manager; D. J. Argall, superintendent of mine; Roy Hatch, superintendent of mill; W. T. Tolch, chief engineer.

Financial Statement: a comparison with previous years is necessary to show the results of this company:

	1918	1917	1916	1915
Revenue from gold	$1,136,223	$2,009,632	$1,837,291	$1,046,104
Operating charges	1,233,168	1,724,474	1,423,260	794,256
Operating profit or loss	−96,945	+285,158	414,031	251,848
Net profit or loss	−116,565	+270,827	+151,026	+278,771
Interest accrued or paid	219,685	258,552	217,747	......
Net income	−336,250	12,275	112,834	
Current assets	692,476	896,087	941,027	695,345
Current liabilities	498,677	635,495	976,713	783,000
Reserves	642,605	325,045	......	......

The liabilities include for 1918 and 1917 notes payable, $400,000 and $500,000; and for 1916 and 1915, bond interest payable, $822,500 and $612,500.

Development: while it is impossible to re-survey the broken ore in stopes, owing to their caved condition, it is estimated roughly at 2,000,000 tons. The quantity in reserve—broken and unbroken—but prospected and prepared between No. 2 shaft and the west end of the property above No. 13 level, is 6,323,117 tons of $1.02 ore. No. 1 shaft, above No. 9 level, is to be abandoned in order to recover the shaft-pillar of 1,500,000 tons of $1.15 ore. The principal mining operations last year consisted in preparing stopes on No. 11 level.



LONGITUDINAL SECTION OF PERSEVERANCE MINE OF THE ALASKA GASTINEAU COMPANY

Production: this might be tabulated as under:

	1918	1917	1916	1915
Ore treated, tons	1,285,445	2,240,346	1,892,788	1,115,294
Average value	$1.090	$1 110	$1 193	$1.157
Recovery, per cent	81 10	81.32	81.33	81 06
Cost of mining	$0.51	$0.42	$0.38	$0.31
Cost of milling	0.33	0.26	0.27	0.31
Total cost	0.96	0.77	0.75	0.71

An average of 452 men were employed in all departments, a decrease of 36%. The wage averaged $4.76, compared with $4.25 in 1917. The number of men now available, and their efficiency, is increasing in marked degree.

Considerable experimentation was done in the mill last year. A hearth furnace superseded the crucible furnace, used for reducing concentrate that carries most of the gold.

HEDLEY GOLD MINING CO.

Property: gold mine, 40-stamp mill, and 1800-hp. power plant at Hedley, British Columbia.

Operating Officials: G. P. Jones, general superintendent

Financial Statement: the net profit in 1918 was $132,578 Current assets total $27,930, and liabilities $10,155.

Dividends: three absorbed $108,000, making $2,412,000 to date

Development: extensions amounted to 190 ft. Reserves are estimated at 263,000 tons of $9.40 and 87,650 tons of $6 ore, a little lower than at last calculations. The value has not decreased with depth, as the 900-ft. level shows the highest grade, which is going under foot.

Production: the mill treated 67,313 tons of $10.34 ore at a cost of about $8.30 per ton.

MODDERFONTEIN DEEP LEVELS, LIMITED

Property: 378 claims (1½ acres each), 70-stamp mill and cyanide plant in the Far East Rand, Transvaal.

Operating Official: H. R. Hill, general manager.

Financial Statement: during 1918 the gold yield was £1,035,473 ($5,019,000). Operations cost £441,622 ($2,143,000), plus £83,175 ($402,000) for taxes, etc., leaving a profit of £519,701 ($2,474,000). The year started with a balance of £126,475 ($611,000), and ended with £157,677 ($761,000), after paying dividends.

Dividends: No. 7 and 8 absorbed £487,500 ($2,362,000), making £1,425,000 ($6,911,000) todate (in 4 years).

Development: the total of new work was 5425 ft. Ore-reserves amount to 3,450,000 tons, averaging 8.8 dwt. per ton, across a stoping-width of 78 in. These figures are an increase above previous ones. Of the ore mined, 85.19% was broken by machines (2.41% by jackhammers) and 14.81% by hand. Water pumped was 29,123,800 gallons.

Production: the mill treated 506,100 tons of 9.945 dwt ore. The duty per stamp-day was 23.7 tons (70 stamps and 8 tube-mills running 305 days). The total gold yield was 243,670 oz., and actual extraction 96.82%. In four years the mill has treated 1,844,500 tons, yielding £3,529,882 ($17,120,000).

Costs: on a basis of per ton milled—$2.38 for all underground work, 84 cents for treatment, and 96 cents for general charges, a total of $4.18 per ton.

There were 255 whites and 2310 natives employed.

PHELPS DODGE CORPORATION

Property: copper mines at Bisbee, Copper Basin, and Morenci; silver-gold mine at Tombstone, Arizona; copper mine at Tyrone, New Mexico; copper mine at Nacozari, Sonora, Mexico; coal mine at Dawson, New Mexico; smelters at Douglas and Morenci, Arizona; and mills at Morenci, Tyrone, and Nacozari; also mercantile stores at the various properties.

Operating Officials: Phelps Dodge Corporation—Gerald Sherman, mining engineer; H. K. Burch, concentrating engineer; C. F. Willis, department of industrial relations. Copper Queen Branch—G. H. Dowell, manager; W. H. Webster, assistant; Arthur Notman, mine superintendent; H. H. Stout, reduction works superintendent; P. B. Butler, assistant. Morenci Branch (Detroit mine)—J. P. Hodgson, manager; W. M. Saben, assistant. Burro Mountain Branch—E. M. Sawyer, manager; E. F. Pelton, mine superintendent. Copper Basin Branch—A. B. Peach, acting manager. Stag Cañon Branch—T. H. O'Brien, manager; J. B. Morrow, superintendent of coke department. Moctezuma Copper Co.—J. S. Williams, Jr., general manager; H. T. Hamilton, manager. Bunker Hill Mines Co.—J. H. Davis, superintendent. Phelps Dodge Mercantile Co.—W. A. Meyer, general manager.

Production: the past three years compare as under:

Metal	1918	1917	1916
Copper, pounds	169,035,687	153,974,692	152,263,729
Gold, ounces	30,434	24,423	28,873
Lead, pounds	1,683,113	8,136,356	10,404,341
Silver, ounces	1,772,119	1,524,632	1,612,055
Average price for copper, cents	24.58	26.67	24.48

Additional to the above for 1918, there was purchased or smelted on toll, ore yielding 43,348,592 lb. of copper, 973,040 oz silver, and 6778 oz. of gold. Copper sold consisted of 279,995,770 lb. of C * Q electrolytic and 14,522,978 lb. of P. D. ingot.

Financial Statement: the total income last year was $59,183,208. Expenses amounted to $43,537,525, including $903,630 for depreciation, $535,375 for Red Cross war funds, and $5,863,585 for all taxes. This left a profit of $15,945,683. Current assets total $39,223,793, and liabilities $15,463,003.

Dividends: these were $10,800,000, equal to 24%, and including that paid on April 2, 1919, the total is $81,221,527.

General: the report of A. T. Thomson, assistant to the president, Walter Douglas, is as follows:

Notwithstanding the general shortage of labor so prevalent throughout the country for the first 10 months of the year, the combined copper production of the various branches and subsidiaries exceeded that of any previous year. In order to keep the production at a maximum it was necessary to transfer men from development to stoping, and consequently the amount of development and exploratory work done was considerably below normal. In spite of this, the ore-reserves in nearly every case show an increase over those of a year ago.

The copper ore extracted from all properties amounted to 2,684,701 tons, of which 106,037 was mined and shipped by lessees. Of the total ores mined, 1,797,161 tons was given preliminary concentration and 887,184 tons was smelted direct. The total amount of copper-bearing material smelted by the company's plants, including ore, concentrates, old slag, scrap and cement copper, was 1,400,911 tons. The copper bullion contained 32,709 oz. of gold and 2,307,307 oz. of silver.

There was also mined and sold 5942 tons of manganese ores and concentrates from the Copper Queen and Bunker Hill mines and 7024 lb. of molybdenite from the Moctezuma Copper Co.'s La Fortuna and Bella Union mines.

Of the ores and concentrates smelted at the reduction works, 1,168,882 tons was developed from the company's properties, 188,074 tons was general custom ores, and 43,955 tons was treated for the United Verde Extension Mining Company.

Unit costs in almost all operations show an increase in sympathy with the increased cost of labor and supplies, although, as a whole, they have not risen to the same degree. Three adjustments of wages in the form of advances were made during the year, so that the wages during the last quarter were paid on a basis of 32-cent copper when the market price was only 26 cents per pound. Up to November 11, 1918, maximum output was being well maintained, but since then the lack of demand for copper has called for a drastic curtailment and reduction in costs.

The total output of the Copper Queen reduction works was the largest in the history of the plant. Much valuable investigation work in connection with metallurgical problems was accomplished during the year, which will now be followed by large-scale tests to prove the results definitely.

At the Copper Queen Branch, credit is due to the mining department for maintaining production with, at times, less than 70% of the normal crew, as well as for keeping the major operating costs down in the face of increasing labor and supply costs. The ore-reserves at the end of the year showed a slight increase.

On Sacramento hill, stripping operations are sufficiently well advanced to estimate that, at the present rate of progress, a production of 4000 tons per day can be maintained after the middle of 1920.

At the Morenci Branch, the year 1918 represents the first full year of operations since 1914. Labor conditions have been normal, but efficiency has been poor. The power situation has been greatly improved by the addition of two new Diesel engines. The present ore-reserves are being completely re-sampled and re-estimated with a view to getting accurate data in connection with future operations.

At the Burro Mountain Branch the production exceeded that of the previous year, and the mining costs were substantially reduced. However, operations have been seriously affected by the drop in copper prices, the ore being of a uniformly low grade. The concentrator changes, when completed, will help here materially.

The Copper Basin Branch produced 1,907,205 lb. of copper from small-scale operations.

The Stag Cañon Branch mined 1,339,292 tons of coal, of which 470,924 tons was consumed in the production of 281,916 tons of coke. The mines and ovens operated continuously throughout the year, and although the output was slightly less than in 1917, due largely to labor shortage, the financial outcome obtained from this branch's operations was very satisfactory. Anticipating a heavy demand for both coal and coke, extensive development work and plant improvements were carried on and the mines put in shape for greatly increased output. After November 11, demand fell off immediately, as a consequence operations have been markedly curtailed. This sudden change in fuel market conditions has made a difficult situation for the coal company. Costs continue high and the Government control of wages still obtains.

The Moctezuma Copper Co. again broke all previous production records and ended the year with a very satisfactory increase in ore-reserves. The wreck of the turbine early in November forced an immediate reduction of output, as no reserve power was available. The armistice, however, followed shortly, so that the loss of production was not felt except as it affected the costs.

Operations of the Bunker Hill Mines Co. are at present confined to leasing on a small but profitable scale.

The average number of men working at the various major branches and subsidiaries in 1918 totaled 11,477. During the past year 647 employees left to enter the Service.

Book Reviews

Mineral Enterprise in China. By William F. Collins. Pp. 308, maps, index. The Macmillan Co., New York, 1918. For sale by 'Mining and Scientific Press'. Price $6.

The most noteworthy thing about this book is its price; but for an engineer who wishes to know about its subject the work is cheap. No similar book is known to the reviewer. In his first chapter the author shows that the ancient Chinese despised mining and regarded miners as the lowest class of citizens—worse even than soldiers. For 2000 years, imperial decrees have alternately permitted and prohibited mining. As late as 1744, gold and silver mines were closed because they attracted workers from the more useful copper and lead mines. Von Richthofen, writing in 1872, mentions the exactions of officials, robberies by workmen, brigandage of neighboring mining companies and, worse than all, the thievery of the soldiers, as causes depressing silver mining. Foreigners who have tried to open mines in China in recent years have been opposed by officials and gentry to such a degree that but few mines are now operated by Europeans. The second chapter is devoted to 'Feng-shui' (wind-water), that pseudo-science whose professors must be consulted every time that the ground is to be disturbed by excavations. Mining necessarily disturbs the beneficent dragon, turtle, or phoenix spirits that regulate the earth currents, and these injuries must be paid for. Disturbing graves is also a serious matter. Fortunately feng-shui is becoming less important. Pages 45 to 77 deal with what Lord Salisbury called the "Battle of the Concessions," an interesting bit of financial and diplomatic history. Five large concessions, granted in 1896 to 1902 by the Peking government are mentioned; every one of these met with fierce opposition— in 1900 the Shansi authorities went so far as to offer a reward for the head of the reviewer. Three of the concessions surrendered their rights to the Chinese for money payment. The Pekin Syndicate, which produced 500,000 tons of coal in 1915, is the only concession working mines. The remaining concession, the Eastern Pioneer, formed by Pritchard Morgan, is still pressing a claim for damages and for the right to work mines in Szechuan. Had Mr. Morgan's plan of forming a Mining Administration for China been carried out it would have resulted in great profits to both Chinese and foreigners, and probably would have checked the encroachments of foreign powers.

The Hanyang iron and steel enterprise, due to the scholar-viceroy, Chang-Chih-tung, is described. The works, with mines and collieries, employ 20,000 men, and turn out 250,000 tons of pig-iron annually. A financial failure from the start, the enterprise has been kept alive by large loans from the Government and from the Japanese; the amount due to the latter is probably not much short of $50,000,000 (Mex.). Iron mining throughout China is now restricted to Chinese. Standard Oil representatives spent $2,500,000 (Mex.) in sinking several wells 3000 ft. in Shensi, near the Yellow river; but finding nothing worth while abandoned the work. Antimony mines, practically monopolized by one Chinese company [the Wah Chang Mining & Smelting Co.] lead the world in production. Several pages are devoted to operations of the Germans in Shantung. The most important mining in China is done by the Chinese Engineering & Mining Co., now raising 70,000 tons of coal weekly. Japanese coal miners, at Fu Shun, near Mukden, produce 6000 tons of coal daily. Other large coal mines and iron furnaces, also near Mukden, at Pen-Hsi-hu, are operated by a Chinese-Japanese company. Near Urga—Outer Mongolia—a Russian company working 7000 men turned out 120 poods (say, 60,000 oz.) of alluvial gold in 1911. The Meho alluvial deposits, near the Amoor river, are the most celebrated in the Chinese republic. It is stated that they produced 100,000 oz. of gold monthly in recent times, but this seems incredible. General conditions affecting mining, legislation, and taxation occupy 50 pages, and eight are devoted to mining in Korea. Of the eight appendixes the most important is a translation of the Mining Enterprise Regulations, promulgated March 11, 1914. The chief mineral of China is coal, of which her stores are immense; iron, antimony, and tin are also important, but do not compare with coal. The fact that rich Chinese miners from the Malay States find it impossible to operate mines in China under present conditions plainly indicates that the chance for profitable investment of foreign capital is very slight. For the individual prospector and small capitalist China is the least promising of the mining countries. It is to be hoped that the sale of the book will warrant a second edition, in which case a few pages should be devoted to a mining bibliography, with notes on the principal works in the Chinese language. A most interesting chapter could be made of native mining methods, and a reproduction of Chinese mining maps with explanations would be entertaining. On the whole the mining profession should be grateful for this little work, which gives evidence of careful study.—W. H. S.

[On page 662 of this issue will be found an article on mining development in China, by Gilmour E. Brown, who fully corroborates the views of Mr. Collins, and the personal experiences of the reviewer.—Editor.]

Industrial Goodwill. By John R. Commons. Pp. 198, index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, $2.

Perhaps the most interesting thing about this book is the frank recognition by the author, himself an outsider, that an outsider cannot know as much about a given industrial dispute as the parties directly concerned. The fundamental idea of the book might be said to be that goodwill between employer and employee must be the foundation for any satisfactory industrial arrangement. The first chapter takes up the old idea that labor is a commodity to be treated like other commodities. Naturally, it does not take long to dispose of that theory. Next comes a discussion of the viewpoint that looks upon a workingman as a machine. While the good work accomplished by the efficiency engineers is recognized, their lack of appreciation of the human element is shown. The interest of the public in industrial relations is then discussed, this interest being the reason for legislation affecting certain industrial relations. However, the author, while in general favoring such measures as compulsory workmen's compensation and health insurance, he makes it clear that the general provisions of industrial legislation should preferably be agreed upon by the men directly concerned in the industry before being presented to the legislative body. In another chapter a strong plea is made for vocational education by the State The author suggests a novel solution for the unemployment problem in the form of a basic day of eight or even less hours per day, thus providing work for practically everybody even during periods of depressions with the further advantage that the allowance for overtime would be the most satisfactory form for sharing the profits of prosperity These are merely some of the 'high points' of a remarkable book. The last chapter is devoted to a brief review of industrial and social conditions since Karl Marx issued his Manifesto in 1848, showing how Marx and his followers guessed wrong and how industrial goodwill can be attained not through socialism but through the use of more rational methods. Reading and even study of this book will well repay both the employer and the labor leader. They will disagree with many of the conclusions expressed, but they will find considerable food for thought.

Office Administration. By J. W. Schulze. P. 290, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by Mining and Scientfic Press', San Francisco. Price, $3.

Office managers and office clerks believing that scientific management would not affect them, that their work was different', have been living in a fool's paradise. The present volume is one of several appearing recently that discuss wastes in office operation and methods of promoting office efficiency. The principal subjects discussed are selection and training of office workers, office layout, establishment of routine processes, filing systems, order and billing systems, handling correspondence, and general office service. The discussion is illustrated by reference to methods actually used in many offices. While a number of these methods are suitable only for offices where hundreds or even thousands of clerks are employed, the manager of the small office will find many helpful suggestions. The weak point about the book is its almost total neglect of the human factor. The reader frequently pauses to wonder how some of the proposed systems would actually work when applied not to automatons, but to real live employees, who could quit if they wanted to do so, and get a job somewhere else. Some idea of this neglect of the human factor may be obtained from the fact that the chapter on the relationship between the employer and employee contains only six pages. Not that there is not plenty of space devoted to training and handling employees. There is, but the discussion is of exactly the same character as that regarding office furniture. Nevertheless, with these reservations, the book has a considerable value for the employer and the office manager.

Mining Manual and Year-Book, 1919. Compiled by W. R. Skinner. Pp. 766, maps, index. May be obtained by writing to W. R. Skinner, 11-12 Clements Lane, London, E. C. 4. Price, 21s. 6d. ($5.25 at normal exchange).

There is little new to be said regarding this useful annual, now in its 33rd year. The matter follows the regular arrangement of metal outputs of the mines of the world, a glossary of terms, full particulars of 1170 companies operating in all quarters, lists of directors, consulting engineers, an appendix of late information, and a supplementary index of 2470 names. A comparison with the previous edition shows that for 1919 to be 163 pages less, discusses 330 fewer companies, lists 220 more in the supplementary index, and the price has been raised from 19s. to 21s. 6d. (60 cents more). But these changes in no way detract from the value of the work.

Trautwine. Civil Engineer's Pocket-Book. 20th edition. Pp. 1528, ill., index. The Trautwine Company, Philadelphia. 1919. For sale by 'Mining and Scientific Press. Price, $6.

The new edition contains about 400 pages re-written since the 19th edition was printed in 1909. These cover mainly railroad engineering and allied subjects, the publishers apparently being under the impression that there has been no progress in any other branch of civil engineering during the past ten years. Furthermore, the pages that have been re-written have not been revised nearly enough. For instance they still contain the old cost data on earth work based on wages of $1 per day of 10 hours of common labor. What Trautwine's pocketbook really needs is a complete revision from cover to cover.

Iron and Steel. By Hugh P. Tiemann. Pp. 514, ill. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, $4.

This is a pocket encyclopedia of the iron and steel industry. The more important terms, such as blast-furnace, heat treatment, and open-hearth process are described fully. The less important ones are either defined briefly, or else cross-referenced to the page of some one of the longer articles where a definition is given. No statement is given of the terms defined but the total must be several thousand.

Mining Decisions

Oil-Wells—Negligence in Keeping Oil Stored

Negligently allowing crude oil to escape from oil leasehold into a creek where it became ignited, was carried down stream and destroyed property, is grounds for recovery of damages by property-owner injured.

Northrup v. Oakes (Oklahoma), 178 Pacific, 266. February 11, 1919.

Oil-Lease—Unlawful Extension of Surface Possession

Where under an oil-lease granting to the lessee possession of so much of the surface as was necessary for sinking wells, the lessee proceeded to sublet sections of the surface to a third party for the erection of buildings and conduct of an oil-well supply business, held, that this use was not contemplated by lease, but that the lessor's remedy lay in suit for damages and not for a forfeiture of the lease and accounting.

Smith v. United Crude Oil Co. (California), 178 Pacific, 141. January 4, 1919.

Negligence of Mine-Owner in Not Informing of Danger

Where plaintiff was an entire stranger to defendant's mine, when taken into a stope and put to work as a miner, defendant owed him the duty of acquainting him with any dangerous conditions of which he had no knowledge, and which would not be apparent to him. The duty did not devolve upon the plaintiff to make the stope safe, and he had the right to assume that the defendant had used reasonable care to discover and remedy all dangerous defects.

Miller v. Utah Consolidated Mining Co. (Utah), 178 Pacific, 771. February 11, 1919.

Mineral Reservation in Deed—Construction

A deed reserved to the grantors the right to mine and remove all ores in and underneath the surface-area, provided certain buildings were not endangered by the operation. Thereafter the grantors in interest began to remove the ores by open-pit methods, which were in common use in mining copper ores in the vicinity. Held, that such mining was within the reserved rights under the deed, and the mining company was not limited to subterranean mining methods in extracting the minerals reserved.

Byron v. Utah Copper Co. (Utah), 178 Pacific, 53. December 28, 1918.

Lode Claim—Inchoate Possessory Rights

Until the actual discovery of mineral in place, all acts tending to consummate a valid lode location give the locator no right other than the right to continue a reasonable search for mineral. If the locator's right to possession of the claim be established, it carries with it the right to possession of the timber soil, country rock, percolating waters, natural springs, except certain mineral springs, and every appurtenant belonging to the realty. But if the locator fails to discover minerals within 90 days from the initiation of his location, under the laws of Arizona his right to exclusive possession terminates, although his actual possession cannot be disturbed until the Government intervenes or some qualified citizen initiates a better claim to the possession of the premises located.

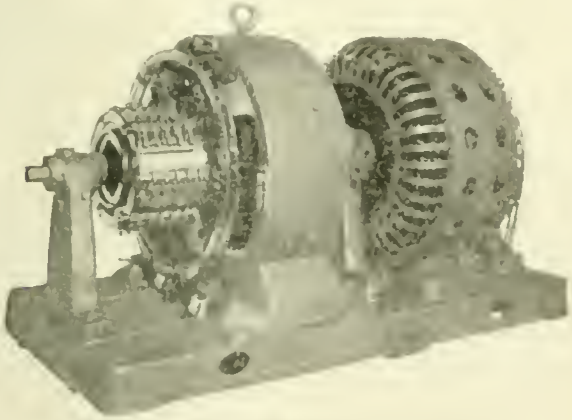
McKenzie v. Moore (Arizona), 176 Pacific, 568. December 14, 1918.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

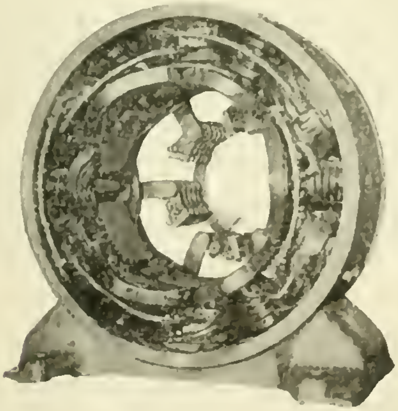
NEW MOTOR-GENERATOR FOR MINE SUB-STATION

There are periods during the day when the electric load of a mine is very light, and then in an instant the demand for power may jump to several times the average. Such conditions occur with the starting or stopping of hoists and locomotives, and demand extra-good peak-load performance of the generating apparatus. This is especially true regarding synchronous motor-generator sets, for the generators are denied the relief afforded by the fall in speed of an engine-driven set, since they run at unvarying speed.



150-KW. SYNCHRONOUS MOTOR-GENERATOR SET

A new synchronous motor-generator set, which embodies the continuous power-factor correction common to such sets with every high overload and peak capacity, has recently been put on the market by the Westinghouse Electric & Mfg. Co. It consists of a type G, 3-phase, 60-cycle, synchronous motor, driving a type SK 150-volt 275-volt compound-generator. The machine has three bearings, the pedestals and field-frames being mounted on a common bed-plate. The full-load rating is based on continuous capacity with 35°C. rise on the generator; 45 C. on motor armature, and 50°C. rise on motor field with 80% power-factor. After a two-hours run at 50% overload, the generator temperature rise will not exceed 55 C., and the motor 55°C. On test, commutation was satisfactory at 250% load. The compound field is adjusted to give 10% increase in voltage from no load to full load.



GENERATOR-FIELD UNIT COMPLETE, SHOWING POLE-FACE COMPENSATING WINDING

In addition to commutating poles of the generator, there is a compensating winding placed in slots in the faces of the main poles. This considerably improves the efficiency and gives extremely good commutating characteristics. As will be seen from the illustration, this winding consists of but one continuous coil per pole. Each coil is form-wound to exact dimensions, and is put into open slots in the pole-faces where it is held by wedges. This construction gives one joint per pole instead of two joints per conductor, as has been the custom in the past, where jumpers were used between bars. No difficulty is found in removing and replacing coils.

The motor is a 6-pole revolving-field machine, provided with squirrel-cage damper winding in the pole-faces. This permits of starting the set from the alternating-current side, and also ensures its stability under sudden variation of load. The field may be over-excited to draw 'leading' reactive current from the line, thus compensating for the 'lagging' current of induction-motors. This helps the voltage regulation, especially where a long transmission-line is used. A voltage-regulator may be employed, which will hold the alternating voltage constant within the range of the set.

The performance of this set is as follows: ½ load, efficiency 81.4%; ¾ load, 85%; full load, 86.5%, and 1¼ load, 88%.

COMMERCIAL PARAGRAPHS

'Rails and Accessories' is the title of Bulletin 258 of **W. A. Zelnicker & Co.** of St. Louis. Copies are free to the trade.

Ben Sweetland, expert advertising agent, announces that his suite in the Singer Building annex, New York, has been doubled in size.

The Acme Motor Truck Co. of Cadillac, Michigan, issues an interesting 14-page monthly, that for March containing descriptions and illustrations of the uses of its motor-trucks.

Fuller & Smith of Cleveland, Ohio, announce that the **Aspromet Company's** name has been changed to the **H. H. Robertson Company.** The firm is manufacturer of asbestos products.

In a leaflet entitled 'A Little Talk About the Jordan', the **O. F. Jordan Co.**, of East Chicago, Indiana, shows the ditching, shouldering, ballast-shaping, and carrying wing on its spreading-machine.

Bone-ash for assayers' cupels is the principal subject discussed in Bulletin 375 of the **Denver Fire Clay Co.**, Denver, Colorado. A cupel machine, sieves, and laboratory crushers are also mentioned.

The Chicago Pneumatic Tool Co. has moved its Milwaukee office from room 1305 Majestic building to room 1418 in the same building, where more convenient quarters necessitated by the growing business of the company in this district have been obtained.

The former Lyons-Atlas Co. of Indianapolis and the former Hill Pump Co. of Anderson, Indiana, have come under a common control and a common management, and will henceforth be known as the **Midwest Engine Co.** The executive offices are in Indianapolis.

In a 79-page general catalogue, the **Fort Pitt Bedding Co.,** of Pittsburgh, Pa., illustrates and briefly describes its many types of beds, bunks, and accessories therefor. Mining companies that have bunk-houses, hospitals, and the like, should find much of interest herein.

Comments of the technical press upon the Crowe vacuum precipitation process, as used in cyanide plants, has been collected and published in pamphlet form by **The Merrill Company** of San Francisco. The system is used in 18 mills in North America, and two elsewhere.

A description and illustration of the **Link-Belt Company's,** of Chicago, Peck overlapping pivoted bucket-carrier for ore, coal, coke, ash, cement, stone, and other materials, will be found in Book No. 220. The buckets hold from 0.68 to 5.25 cu. ft., and are made of malleable iron.

Correction. In the March 1 issue it was stated in error that the **Denver Engineering Works,** Denver, Colorado, recently furnished ball-mills for the new mill at the U. S. S. R. & M. Co. at Eureka, Colorado. The principal grinding at the Sunnyside plant is done in Marcy mills.

The E. I. du Pont de Nemours & Co. announces that T. E. Doremus has been transferred to the company's export department as general Eastern manager, with headquarters at Shanghai, China. E. R. Galvin has been appointed manager of the sporting powder division to succeed Mr. Doremus.

The Marthon Mill Machinery Works, First National Bank Bdg., Chicago, is a new company that has been organized to take over the Marathon mill and other machinery formerly manufactured and sold by the Johnson Engineering Works. The latter will devote its attention to other lines of machinery.

D. Gleisen, chairman of the Board of Managers, industrial divisions, **General Motors Corporation,** and manager of the industrial bearings division **Hyatt Roller Bearing Co.,** announces the appointment of P. C. Funion as advertising manager for the industrial divisions, General Motors Corporation.

E. D. Bullard announces his new catalogue of carbide lamps, oxy-acetylene equipment, and safety supplies. Purchasing offices of mines, shipyards, manufacturers, welding-shops, etc., will probably be interested in this booklet, which will be supplied on application to 268 Market street, San Francisco.

'Mine and Quarry' for March, the monthly of the **Sullivan Machinery Co.** of Chicago, contains several readable articles, including 'Drill Sharpener Speeds Up Shipbuilding', 'Diamond-Drills Pick Dam Location', 'Heavy Drilling at Sacramento Hill, Bisbee', Sullivan Straight-Line Compressor with Plate-Valves', and 'Air-Lift Boosts Artesian Well Flow'.

The Huff Electrostatic Separator Co., having outgrown its plant at 60 India street, Boston, announces the opening of its new offices, laboratories, and works at Mystic and Summer streets, Arlington, Massachusetts, where it will maintain a fully-equipped modern laboratory and conduct investigations embracing all ore-dressing, metallurgical, and milling problems.

A splendid new building has just been completed for **Rosenburg & Co.,** machinery distributors of Los Angeles. This firm reports large sales of re-built machinery for Arizona and has also recently made a number of shipments to nearly every Western State. The company's recent large purchase of mining equipment has been attracting much attention, aand the stock is being rapidly sold.

The Dobbins Core Drill Co. of New York City announces the appointment of Harron, Rickard & McCone as its representatives in San Francisco, Los Angeles, and surrounting territory. The Salt Lake Hardware Co. has been appointed representative for the district contiguous to Salt Lake City. A new and interesting catalog has been issued by the Dobbins company describing its core-drills.

C. H. Ramsden, formerly chief engineer for the Western Pipe & Steel Co. of California; W. F. Focha, and Captain C. A. Duffie, who has just been discharged from the Army, have formed the **Steel Tank & Pipe Co. of California.** A modern plant for the fabrication of riveted-steel tanks and pipe is now under construction at Berkeley, California, and San Francisco offices have been opened at 241 Hansford building.

Smith, Emery & Co., chemical engineers and chemists of San Francisco and Los Angeles, have well under way the plans for a cement mill to be erected in an undisturbed part of Mexico. Materials to be used consist of limestone and natural pozzuolana. The preliminary burnings and engineering test have shown a sound, cheaply-produced portland cement. The capital, it is understood, is being furnished jointly by American and Mexican financiers.

Six **Oliver** filters, 12 by 16 ft., with complete vacuum-plant, have been ordered by the American Smelters Securities Co. for its Veta Grande mill at Parral, Chihuahua, Mexico. The Alvarado M. & M. Co. at Parral has one 12 by 18 and one 14 by 18-ft. Oliver filter. The vacuum equipment mentioned consists of a 23 by 12-in. duplex Imperial type XB-1 Ingersoll-Rand dry vacuum-pump, a 3-in. ball-bearing centrifugal pump, and Oliver vacuum receivers.

In Bulletin 34, the **Lidgerwood Manufacturing Co.,** whose works are at Brooklyn, N. Y., and Newark, N. J., describes and illustrates the operation of its coal-handling cableways. This device has proved successful on coal-storage work, where the ground available for storage could hardly be used with any other method. The firm has only recently looked into this field, and from investigation finds that there is little knowledge among engineers of the possibility of the cableway for this kind of work.

The Merrill Metallurgical Co. of San Francisco announces that the expansion of the business and professional work of the firm due to the increased use of its apparatus and processes and the acquisition of other processes, products, agencies, and devices, has necessitated the enlargement of its staff and facilities and made advisable incorporation of **The Merrill Co.** The new company takes over the patents and commercial business of its predecessor, and will continue to enlarge its scope as new devices and products become available, which it is justified in presenting to its clients as of unquestionable merit and efficiency. Charles W. Merrill is president.

A handsome 88-page loose-leaf catalogue is the novelty just sent us by the **Justrite Manufacturing Co.,** of Chicago As new goods are made or articles or prices changed, new leaves for insertion will be sent for addition or substitution The company eight years ago developed and offered the Justrite miners' carbide lamp, but in this catalog illustrates and describes 42 distinct types of lamps and in many combinations manufactured by it. Mining companies will find this publication worth filing, as in it will be found the various lamps, their size, weight, charge of carbide, candle-power, burning capacity in hours, and prices; also data on repair parts.

EDITORIAL

WHEN the Germans, who managed to keep the war out of their own country and thereby, except for a part of East Prussia, escaped the horrors they visited on their neighbors, protest against the terms of peace, it is well to remember that the damage they did in France is estimated at 21 billion dollars, or about as much as the total war debt of the United States. They destroyed 22,999 factories, or about one-sixth of all the factories in France and about one-half the entire value of French property in factories. They destroyed 240,999 homes. Just imagine one of these homes to be your own.

UNDER the heading of 'Discussion' we publish a letter from Mr. Morton Webber in which he makes clear his professional connection with the Butte Copper Czar mine, which is the subject of a circular recently issued for the purpose of explaining the proposal to find fresh capital for this enterprise. We are glad at all times to give the use of our columns to members of the profession in the defence of their reputations. If a man stands right with the members of his profession, it matters little what the public thinks, because in the end the public must take its cue from those who are best informed.

IN this issue we publish the text of the oral argument made before the U. S. Supreme Court by counsel for the Minerals Separation company in the final hearing of the case against the Butte & Superior company, on appeal from the Ninth Circuit Court in San Francisco. The patentees, who are the petitioners, were represented by Messrs. Henry D. Williams and W. Houston Kenyon, both of whom made good arguments for their clients. Next week we shall give our readers an opportunity to read the argument on the other side, namely, the one made by Mr. J. Edgar Bull for the Butte & Superior company. The colloquies between counsel and members of the Court are particularly interesting to those who have followed this litigation.

CARRANZA'S government, it will be recalled, has refused to recognize the financial clause in the Armistice by which Germany pledged herself to the Allied governments not to dispose of her stocks in specie or any of her foreign title-deeds or bonds abroad, whether in possession of the Government, the savings-banks, private persons, or companies, without the previous consent of the Allies. In a note delivered to the French government on April 28, the Mexican government took the stand that these engagements made by Germany in the Armistice are contrary to the Mexican constitution and to the terms of the treaty between Germany and Mexico. This applies to the holdings of the American Metal Company and its subsidiaries in Mexico, all of which are detailed in the report of the Alien Property Custodian.

EXPORTS of copper during the last two months have fallen to 5966 and 4218 tons respectively in March and April, as compared with 31,188 and 23,811 tons in the corresponding months of last year. In January 1917 American exports of copper reached the maximum of 51,322 tons. If the present production be estimated at 125 million pounds per month, it is evident that the April exports represent 8% as against the normal 40% exportation from this country. As France and Italy are closed by governmental decree to the importation of American copper, and as England has on hand a tonnage nearly equal to that imported in 1913, it is evident that there will be no noteworthy improvement in the foreign demand until the signing of the Peace Treaty restores business communication with Germany and other parts of Central Europe.

IN April 1918 the Government, by authorization of the Pittman Act, began the melting of the 490,000,000 silver dollars hoarded in the Treasury. This was done to meet the urgent requirements of the British government of India. Within a year $250,000,000 worth of silver was shipped from the American mints, and of this 200,000,000 fine ounces were sold for the use of the Indian government. Concurrently the price of silver was fixed at $1.01½ per ounce and an embargo was placed upon private, as against governmental, exportation of silver. The lifting of this embargo caused the price of silver to rise promptly to a maximum of slightly over $1.20, followed by a recession during the last week to a low quotation of $1.10 per ounce. The prospects for a higher price are good, but the coinage ratio of $1.29, of course, will be the limit to which the quotation can go.

THE Institute bulletin for May contains a strange collection of reading-matter, including two pages of graphic diagrams showing the trend of the bond and stock markets, besides two other pages devoted to the annual dinner of the Rocky Mountain Club. Are these in their right place? Now that paper, printing, and postage are so expensive, is it well to incur the unnecessary expense of publishing irrelevant matter such as this? The Rocky Mountain Club has no connection with the profession or with the purposes of the Institute, nor are the antics of its members of more than ephemeral local interest to anybody. However, the bulletin does include, besides the text of the various papers contributed to the Transactions, a report of the symposium, held recently at New York, on 'The Engineer as a Citizen'. This is well worthy of inclusion.

OPTIMISM continues to characterize the mood of the American people. Their buying capacity appears to be hardly affected by conditions overseas, and the general trade of the country, in consequence, is lively and large. Undoubtedly the prosperity of the farmer, due to an abnormally good market and unusually big crops, is having its stimulating effect on business generally. Construction work is checked by the prevailing high prices of labor and materials, but the erection of houses, at least, cannot be much delayed, owing to the urgent demand created by the cessation of building during the active period of the War. The mining industry is suffering from the effects of an overstocked metal market and will not resume its normal expansion until the signing of the Treaty of Peace removes the barriers to international business that have arisen from a state of war; nevertheless there is a good deal of activity, especially in the search for the precious metals. The rise in the cost of labor has been corrected by the curtailment of operations at most of the copper and zinc mines, but no satisfactory adjustment of wages is likely until the output of food-stuffs in the belligerent countries is renewed in such volume as to restore the normal supply of the world and thereby reduce the cost of living.

RESUMPTION of work at the Argonaut and Kennedy mines is announced, and we are glad to record the fact. The fire underground, which was the cause of the interruption to the productive activities of these two important Californian mines, is under control, and will shortly be totally extinguished. References to the Argonaut as the deepest mine in the world, and so forth, have appeared in the local press. Therefore it may be well to state that the deepest metal mine in the world is the St. John del Rey, in Brazil. This famous old gold mine has reached a vertical depth of 6326 feet. On the Rand the Jupiter is 5040 feet, the Simmer Deep is 4780 feet, the Cinderella 4627 feet, and the Village Deep 4245 feet in vertical depth. The Brazilian and the South African mines are about three thousand feet deeper on the dip of the lodes than the figures quoted, but 'depth', of course, is the distance from surface. On the Kolar goldfield, in India, the Ooregum is 5250 feet and the Champion Reef 5380 feet deep. In the Lake Superior copper country the Tamarack No. 5 shaft is 5368 feet and the Tamarack No. 3 is 5281 feet. At Bendigo, in Australia, the Victoria Reef Quartz mine reached a depth of 4614 feet. The Argonaut is 4600 feet on the dip, or 3900 feet vertical, whereas the Kennedy is 4050 feet deep vertically. The world is a large place, therefore it is dangerous to make hasty generalizations. As a matter of fact the Argonaut and Kennedy mines are a thousand feet short of being remarkably deep, fortunately for their owners.

WE take pleasure in publishing a careful and comprehensive article on the oil-shale industry, with particular reference to Colorado, by Mr. Arthur J. Hoskin, of Denver. The subject is one well worthy the attention of the profession, even to those having no idea at present of becoming engaged in the exploitation of oil-shale, because it involves a number of interesting technical problems and it promises to be of increasing importance to the community. Long after our oil-wells cease to flow, either naturally or by mechanical means, the winning of oil from shale is likely to be engaging the activities of enterprising men. Mr. Hoskin, quite properly, does not give much space to the oil-shale industry as developed in foreign countries, in Scotland and Australia, for example, because the conditions abroad are so different from those with which we have to deal in our own country; indeed, American writings on this subject heretofore have been rich in details of foreign practice and poor in the information required more immediately for domestic exploitation. The technology of the subject offers several interesting phases, which Mr. Hoskin discusses usefully; but, after all, the commercial phase is the decisive factor, namely, the production of oil good enough and cheap enough to compete successfully with the wells from which we now obtain our supplies of liquid fuel.

The Metal Octopus

In our last issue we published the last of four instalments of the report issued by the Alien Property Custodian on the operations of the German metal octopus, namely, the group of metal-dealers headed by the Metallgesellschaft of Frankfort, in combination with Aron Hirsch & Sohn of Halberstadt, and Beer, Sondheimer & Company of Frankfort, together with their various associates and agents, including the American Metal Company, Henry R. Merton & Co., L. Vogelstein & Co., and their subsidiaries. We have thought it worth while to give so much space to this report because it contains information valuable to all those engaged in the production and selling of metals, and because the report emanates from a source in which we and our readers can have confidence. Mr. A. Mitchell Palmer was appointed Alien Property Custodian by the President as soon as the control and disposal of enemy business made such a Federal department necessary, and when, a few months ago, Mr. Palmer became U. S. Attorney General, he was succeeded by his first assistant, Mr. Francis P. Garvan. It is not stated who prepared the report on the German metal business, but we hazard the guess that Mr. Garvan, who was director of the Bureau of Investigation, deserves chief credit for it. It is unfortunate that the author of the report did not avail himself more of technical assistance, because some of the references to metallurgical processes are needlessly inaccurate. The Custodian has retained several of the former directors of the American Metal Company in office and it would appear reasonable to expect that from them, or through them, for example, he could have obtained the assistance required for the purpose of straightening the wrinkles in his metallurgy. However these minor blemishes do not affect the main purpose of the report, which is to disclose the ramifications of a combination that was threatening the mineral industry of the whole world. We have referred to the subject several times in these columns during the last four years, being first prompted to do so by the disclosures made in the Snow trial at Adelaide, in South Australia, at the end of 1914. The correspondence placed in evidence in that case showed how the various German firms aided each other in selling metals to Germany in disregard of the Australian law enacted at the commencement of hostilities. At the same time it was shown that 89% of the zinc output and 95% of the copper output of Australia was controlled by these German firms. The Custodian's report proves how the same commercial penetration had succeeded, before the War, in controlling a large part of the metal business of this country; it exposes the methods by which the members of these firms evaded war-time regulations by transferring their business to American agents or by going through the process of naturalization. Now, it appears to us quite clear that much of this pernicious activity, especially the industrial syndication, was objectionable in itself, not merely because it was German. The fact that it originated from an enemy country enabled the agents of our Government, and of the British government, to make a legal inquisition into its methods and manifestations, but it was destructive to business enterprise in the English-speaking countries not because it was German but because it was in restraint of trade. The Federal Trade Commission published its own report, to the same purpose, and we gave our readers the gist of it in our issue of January 19, 1918. The combination in restraint of trade, whereby these German syndicates were enabled to move the metal markets in their own interest was bad whether it was German, American, or British. Indeed, we go so far as to say that it was largely non-national in its spirit, it owed allegiance not to the kaiser but to the mark, the dollar, or the pound sterling, whichever was nearest; it was 'peeziness'; for it must be recognized that it was in the hands of Jews almost without exception. Even that eminently English name 'Merton' was mere camouflage, for the real name of the founder of Henry R. Merton & Co. was Moses, a cousin of the Cohen that founded the Metallgesellschaft. The fact is that the traffic in metals, with its intricacies and trickeries, suits the Jew so well that he has gradually acquired control of the world's trade. If the Australians allowed 80% of the products of their base-metal mines to be controlled by the German-Jew agencies, it was largely their own fault. If the British allowed the Australian zinc output, which was just equal to the British domestic consumption, to sail past their ports to Hamburg and Rotterdam, on consignment to German-Jew dealers, it was largely their fault also. If the American producers exercised so little sagacity as to permit themselves to be gathered within the tentacles of this octopus, they also have only themselves to blame. The members of this commercial cuttlefish wanted to do business, that is, to make money, and they used all the tricks of the trade to effect their purpose. They persuaded the German banks to finance them, they stood together against the producers, they assumed any nationality that suited them, even registering their German companies in London in order to obtain protection in their South American trade, and naturalizing themselves in the United States in order to evade the military embargo. In all this they were not working so much for Germany as for themselves, they were non-national in their aims, they were "after the stuff" and they got it. It will be a blunder if in our anti-German enthusiasm we, that is, the American producers of metals, assume that the exposure of the German system and the seizure of their property in this country will put an end to the metal-brokers' control of the market. The Custodian, thanks to the exigencies of war, has released American and Mexican mining enterprises from "the dominance of Germany-owned corporations", as a Washington telegram says. The Custodian himself says, "it is believed that the German influences in our metal markets have been completely eliminated." This has been done by selling the German shareholdings in the American metal firms to American capitalists, and, concurrently, German shares in British firms have passed into English hands. So far, so good; but all danger has not been escaped, for many of the former directors are still on the boards of these companies and they are co-operating with the new directors, who were either nominated by the Custodian or are on the boards by reason of their purchase, by auction, of large blocks of shares. Business is non-moral and, except in times of national crisis, non-patriotic. It is quite on the cards that the new controllers of these concerns may get an oppressive grip on the metal market. During war a German control might be worse than an American or a British control, but in time of peace any control in restraint of trade will be obnoxious, no matter what the nationality of the combination. The producers should remain on their guard, and not lull themselves into a false sense of security. They must devise some means of protection. They suffer from the fact that the big custom-smelting companies both own mines and control metal-selling agencies. By owning mines they can ensure a part of their needed supply of ore and thereby apply the discipline of the sand-bag to recalcitrant customers; through their metal-selling agencies they hold an advantage over the ore-producer. It is against the law now for the anthracite coal companies to control the public railways used in their business because it was found that the interplay of ownership was detrimental to the welfare of the community. It might be well if custom smelters were debarred from owning mines or from engaging in metal-dealing outside their own production; indeed, the threat, made in Colorado, for example, of placing the smelters in the category of public utilities, thereby subjecting them to the State Commission created to supervise such business activities, is one that we would like to see put into force, if only we were sure that it would be used fairly. We know, of course, that the regulations for inter-State business are evaded by the smelters; they agree to cut their lawns on the same day or to look out of the window when politeness requires it; they do not compete unreservedly, and they enjoy sundry railroad freight-rates that are difficult to explain except on grounds similar to those that give 'inflooence' to O'Flaherty. Another escape from cuttlefishes is to organize an independent ore-producers selling agency for self-protection, that is, to meet collective buying with collective selling. It is an interesting problem and one to which we shall be glad to give space, if any of our readers care to express their views.

A Post-Mortem

In our issue of February 15 we discussed the record of the Camp Bird mining company and that of its Mexican subsidiary, the Santa Gertrudis. We have now been placed in possession of additional information, which is interesting, besides being corrective and supplementary. The Santa Gertrudis promotion was started by a syndicate, formed in 1909, consisting of Messrs. John Hays Hammond, Cortlandt E. Palmer, Hugh Rose, and Frank W. Royer, all well-known mining engineers. The first mine taken under option by this syndicate was the La Blanca at Pachuca. It was examined by Mr. Royer and a competent staff, the results being so favorable that it was decided to offer the property to the Camp Bird company, which accepted the option and sent Messrs. R. J. Frecheville, W. J. Cox, and E. E. Chase to examine the mine. Prior to the arrival of these engineers the promoters had induced the La Blanca company to start some winzes on the vein from the bottom level. At the time when the Camp Bird engineers arrived at Pachuca these winzes were giving evidence that the ore-shoot was shortening in depth. Meanwhile Mr. Royer had begun an examination of a neighboring mine, the Santa Gertrudis, with results so favorable that it was decided to offer the option, which had been obtained by the syndicate, to the Camp Bird company in lieu of the option on the La Blanca. Messrs. Frecheville, Cox, and Chase recommended the purchase of the Santa Gertrudis and the transaction was duly completed, on the terms quoted in our previous editorial. The appraisal of the Camp Bird engineers seemed justified by the evidence obtainable underground. The 17th level showed the ore-shoot at its best on that level, which was the deepest in the mine; the 18th level subsequently showed further improvement, the orebody being 1600 feet long, 15 feet wide, and averaging 39.3 ounces in silver, with $3.90 in gold per short ton. Every 100 feet of an orebody of this size and richness represented $3,750,000 net profit, the silver being taken at 59 cents per ounce. Competent engineers, of course, recognize the danger of estimating both the yield and the persistence of such high-grade ore-shoots, and they face a risk in recommending the purchase of such mines as the Santa Gertrudis, which are not purchasable at a price fully covered by the ore assured. The purchase is a sane speculation based upon a reasonable expectation of the continuance of the ore below the bottom workings. In this case the expectation of continuance was based upon the record of other mines in the Pachuca district, and it seemed to them that the increasing strength of the Santa Gertrudis orebody down to the 17th level warranted the anticipation that it might continue to a further depth of 450 feet. Such did not prove to be the case. The 18th level more than fulfilled expectations, as already stated, but on the 19th the ore averaged only about one-third its assay-value on the 18th level, and the 20th level practically bottomed the ore-shoot. Although the country-rock did not change, nor were the structural conditions different, yet the mineralization seemed to end abruptly. On the other hand, whereas only 150,000 tons of fill in old stopes was included in the estimate of reserves, the former workings yielded more than a million tons of low-grade ore. Moreover, the Mexican revolution and the European war caused a loss of $1,500,000 in possible profit. Such is the post-mortem of the Santa Gertrudis. It confirms our previous autopsy. In fairness to three members of the syndicate it should be recorded—although we suggested nothing to the contrary—that Messrs. Palmer, Rose, and Royer had no professional connection with the Camp Bird company at the time of the purchase of the Santa Gertrudis; they simply examined the mine on their own account before offering it for sale. Mr. Hammond, consulting engineer to the Camp Bird company, had a quarter interest in the business; and as regards him it is fair to add that at first he advised against the purchase, being guided thereto by the adverse report of Mr. M. H. Burnham, whose opinion was set aside subsequently by a most painstaking inspection made by Mr. F. F. Sharpless. Mr. Rose became manager for the Camp Bird after the purchase had been completed. Largely on his initiative, the life of the enterprise has been lengthened profitably by the recent acquisition of the El Bordo property, another neighboring group of mines. All this does not palliate the extraordinary conduct of the directors in London, and of their consulting engineer, at the time of the flotation. They participated in the profits of the various underwritings and commissions—all except Mr. W. F. Fisher, who resigned from the board. An issue of preferred stock was guaranteed by the chairman and his friends for a commission of 10%, making $325,000. The total sum received by the consulting engineer and the directors altogether amounted to $775,000. These facts were disclosed at the time and the shareholders made no protest. Of course, the directors were serving as trustees for the shareholders and they should have done nothing of the kind so long as they occupied a fiduciary position. In the end Mr. Arthur M. Grenfell, the chairman, became badly involved in his dealings between the Camp Bird and other companies and went into bankruptcy just before the War, in which he did his duty as became the member of a family of gallant soldiers. The whole story is worthy of record. It carries its own moral, which we forbear further to emphasize.

DISCUSSION

Re-financing of the Butte Copper Czar

The Editor:

Sir—I beg to submit a circular which has been handed to me in respect to a proposal for re-financing the Butte Copper Czar Mining Co., the property of which is located at Butte, Montana. As I am the engineer mentioned in the circular, I feel, in the interest of the public, the facts should be known. I herewith quote part of the text of the circular.

"During the year of 1918, development work was carried on by a New York Company, with Mr. Morton Webber in charge. A station was cut on the 300-foot level, together with sump for water. There were 510 feet of cross-cut driven and after the vein was encountered 477 feet of drifting was done on the vein. The vein on this level varied from 4 feet to 8 feet wide, and is highly mineralized, proving an ore-chute continuous for more than 300 feet, carrying good values in silver and copper. Unfortunately, Mr. Webber did not come within 100 feet of the ore-chute where commercial ore shows above. On account of the high cost of labor and supplies the New York people decided to drop the option on the control of the Company and all stock not paid for has been turned back to the Treasurer of the Company, making a balance of 312,888 shares remaining in the treasury."

From the above it would appear by innuendo that the work entrusted to my charge had been performed in an incompetent manner. It would also appear that the whole basis for re-financing is that, owing to the incompetence exhibited in my management, the property did not get a fair trial. As for example: "Unfortunately, Mr. Webber did not come within 100 feet of the ore-chute where commercial ore shows above." This is a misrepresentation of fact. The ore-shoot shown in the surface workings constituted an attractive mining speculation. The development of the downward prolongation of this shoot was clearly the crux on which the future possibilities of the property would largely depend. I was thoroughly alive to the importance of this phase of the work. The drifting done under my direction clearly indicated that the ore-shoot did not persist in depth as my exploration would have caught the shoot, allowing for a rake of 45° either way from the vertical.

The circular also states: "The vein on this level varies from four to eight feet wide, and is highly mineralized, proving an ore-chute continuous for more than three hundred feet, carrying good values in silver and copper." I beg to state that this level was sampled under my direction and there were no values such as this statement might indicate; although the term "good values" is ambiguous. The highest assays that were ever obtained were less than 2% copper and two to three ounces in silver; and these were only in spots.

The circular also states, "On account of the high cost of labor and supplies, the New York people decided to drop the option on the control of the Company and all stock not paid for has been turned back to the Treasurer of the Company." There is no foundation for this statement. The corporation which I represented in this work has between three and four million dollars in liquid assets, and operations were terminated only on my advice that the development work we had done demonstrated that the prospects of the mine were very unfavorable; that further expenditure would mean further loss.

I write this letter in the interests of the public and also that I do not propose to sit calmly by and witness a re-financing the basis of which is evidently that I did not know my business. If there is any question as to who is right, I will suggest that the stockholders, before proceeding to re-financing, will first employ an independent engineer to report on the merit of the enterprise. A prime essential in his selection should be that his professional standing would carry the guarantee that he would be without prejudice.

MORTON WEBBER.

New York, May 14, 1919.

Mine Labor

The Editor:

Sir—The fourth paragraph on top of page 610 in the March Bulletin of the A. I. M. E., in Will L. Clark's vigorous discussion of Herbert M. Wilson's paper, 'Employment of Mine Labor', shows the American youth to have a hard future before him, because he is constitutionally hungry and opposed to steady work. The former characteristic reminds me of landing at the Bullion mine, in Idaho, some years ago, and my hostess asking if I were not hungry, when two little girls piped up, "I'se hungry, Mamma." Answer: "Oh you 'uns are always hungry." And another but recent scene in my own dining-room when my daughter had left a handsome piece of cake alone with her brother of sixteen, who, however, was six feet and weighed 165 lb. What became of it may be surmised from the conversation that floated from the room. There was probably an appeal for forgiveness. "Go away, don't touch me, you're a pig, and you have three brothers and they were pigs too, I know, I was brought up with them." The same boy increased his age two years between the house and the recruiting stations and has been with the First Division for 17 months, and is with it now in Germany. His notes did not express any wish to be elsewhere than he was, perhaps he had not time to think about it, it was always "going day and night."

Possibly the "observer," mentioned in that paragraph, saw more of the rear camps than the front trenches. The same lad's eldest brother resigned his position to join the 25th Engineers, and he did seem to fret a little at only building supply-depots and railways in a non-combatant area, but going through the Argonne drive seems to have restored his spirits, and I do not hear any complaint from his long stay at Brest, although each month is a serious loss of time to him.

Regarding our men being broke, we might expect it from the most vigorous and ambitious youth of the land working in a strange country, on camp fare, for, say, $10 per month, after deductions are made from the $30. Since the wage question was settled by Congress I have had a sense of shame at the pittance, when we at home were prospering because of the War, and not the least those whose income was affected by the price of copper.

Referring to Californian garden work, it would be interesting to know the wages paid per hour, the amount this represents per pound of fruit, the ages of the Japanese, Chinese, etc., and whether the American youth have been idle while these were working. I remember my particular chum in old Californian days, who lived just outside San Jose, learning his lessons with the books hanging on the handle of the plow while attending the State Normal, and who would leave at 4:30 a.m. with a load of hay for town, returning in time to dress nicely for school. At Denver one of my own sons announced that during the high-school summer holiday he was going to Boulder to work on a ranch. I expected him back in a few days, but he only returned, with his pockets full of money from $20 per month, in time to buy a new suit of clothes and enter school. Afterward, returning from Mexico through Arizona, he stayed to work underground in a large copper mine, reducing his weight from 165 lb. to 135 lb. in 30 days, after which time he was discharged by a foreign shift-boss. However, he came north, and, through the kindness of the companies he has worked for, has not lost a day's wages in seven years.

Coming to foreigners and a mine employing 80% of them, I am reminded of the change from an Irish to a Cornish foreman of the mine. "And now the Irish are coming down the hill and the Cousin Jacks are going up." What do we mean by foreigners? Is it those who keep to themselves, usually getting a lower wage than the Anglo-Celtic or mixed nationalities? During the first year of the War I did tunnelling with a crew of one Canadian, who had two brothers in France, two Irishmen, two Germans, one Austrian, and two Americans. There was lots of chaffing, but no bitterness, for all were really Americans, and each was a splendid worker, well-informed and intelligent. I added ten dollars to the Austrian's check when he left, for "a good dinner in town on the company's account."

The worst time-killing laborers I have seen have been the real foreigner, from the Chinese in the old days in California to the south-eastern European of today. I have thought this slackness was accompanied by a lack of self-respect, repugnant to a man of better mentality.

I have often wondered, seeing criticisms by employers of their employees, in what country the employer could have secured happier results. At an Institute meeting, since we entered the War, one of the prominent managers in an important mining community stated what we have heard so often, that the work done per man had decreased as the wages increased. I was on the alert and sought him after adjournment; he said: "That is what the other managers tell me; in our case a bonus system was arranged which resulted in our getting more than the highest wages, while the work cost less than in pre-War times." This may have been extra exertion by the men and better arrangements by the management.

My opportunity for observation has not been varied during the War, but I judge that Americans are as appreciative of higher wages as the distinctly foreigners, that they stayed with their jobs pretty well, and there was no difference in the amount of work performed. Those leaving were mostly poor workmen and their move was a benefit to the employer. We are all in the same boat in this world, living from hand to mouth on the season's production, and we need a strong pull and a pull altogether.

Mr. Clark mentions the advantage of work about the copper plants; I think it offers excellent opportunity for earnest young men wishing to earn money for a college course. They could save enough in three years or less for a comfortable four years course and the summer vacations. During the three years the equivalent of two hours daily could be spent in study, besides time for general reading, equivalent to a solid year of six hours daily. Much thinking and actual assimilation can go on during working-hours, as the mind is largely free and often enough the hands. JOHN B. HASTINGS.

Los Angeles, May 4.

THE GRAPHITE-MINING INDUSTRY is dependent directly upon the metal industries. The use of graphite in the manufacture of crucibles, of foundry facings, and of lubricants furnishes the link that ties the two industries. The steel business consumes 30 to 40% of the graphite crucibles manufactured. In October last, of the 39 mills in Alabama, 21 were operating; in April, only 11 were at work.—G. D. Dub in April report of U. S. Bureau of Mines.

SPELTER PRODUCTION per retort in the United States is slightly over four tons per annum. Elimination of much of the lower grades of ores has increased the output.

IRON in sand used for optical glass must be very little —from 0.004 to 0.02% Fe_2O_3.

The Winning of Oil From Rocks

By ARTHUR J. HOSKIN

During the past two years considerable attention has been given to certain natural resources that may eventually prove the basis of one of America's greatest industries. The existence of combustible shale in several States has been known for many years. Here and there, in separate parts of our country, Indians, settlers, ranchmen, and surveyors long ago found rocks that would burn. Occasionally such a discovery was attended with disaster, as in the case of a Western school-house burning to the ground because its 'stone' fireplace proved combustible. A few relics of primitive attempts to utilize such rocks in the manufacture of 'coal-oil' may be found here and there, both in the East and in the West. Near Moab, in Utah, is a small retort said to have been built for this purpose by Mormon pioneers. A gulch in the hills near Dillon, in Montana, is known as Coal creek because a few early ranchmen here derived their fuel for domestic purposes from an outcropping ledge of shale, which they assumed to be a peculiar low-grade coal. A surveyor who, years ago, assisted in subdividing into sections a portion of the 'western slope' of Colorado told me it was common for his camping party to utilize the shale as fuel for cooking and heating.

So I conclude that we Americans have ignored for a long time a resource of significance, a resource that is perhaps even now coming in for serious recognition merely because of alarming statistics promulgated by our Federal bureaus regarding the diminishing sources of motor-fuel.

Foreign Shale Industry. The authors of articles on this subject in American journals seem to think it necessary to review at length the oil-shale industry that has thrived abroad, especially in Scotland, France, and Germany for many years, and from such foreign data to draw conclusions as to what we may and should accomplish with similar shales in this country. The industry in France dates back 89 years, whereas that in Scotland has been active for about 60 years. I shall not gainsay a single statement concerning the established foreign oil-shale industries. I do, however, raise the point that there is so much dissimilarity between the American and the Scotch shales, for instance, that it is a mistake to draw close analogies as to what we may accomplish with our own deposits. Metallurgists know well that slight differences in the physical or chemical composition of ores of a single metal frequently call for different methods of treatment to recover that metal. Coal men know that very slight, often invisible, variations in coal from different neighboring mines have vital significance in coking qualities. So it is with regard to oil-shales, not only as to differences between such rocks in widely separated regions of the world, but, to a notable degree, between deposits in the same region and even as between contiguous strata. It is a fact that the majority of the American oil-shales differ radically from the Scotch shales in their geologic occurrence, their chemical composition, their texture, and especially in the products they will yield. Therefore, except by way of drawing vague comparisons, we should not base any plans for commercializing American oil-shales upon practices and successes in Scotland or elsewhere. For this reason, then, I shall restrict my discussion to conditions existing in the United States.

The American Shale Industry. Although, as explained, there had long been some knowledge of such rocks in this country, it was not until about two years ago that general credence was given by the public to these resources. It was during the summer of 1916 that the first adventures were made into this new field of industry. A few men read the description of Scottish practice and erected experimental retorts copied from drawings in books. The experiments in general were disappointing. Undaunted by failure and spurred by the potentialities, these men became inventive, and we must credit them with whatever success has thus far been developed in this industry, which is really new so far as America is concerned.

The Oil-Shales. The term 'oil-shale' is a misnomer. A better name for rocks of this sort is 'bituminous shale'. An oil-sand carries native oil or petroleum, whereas an oil-shale contains no oil or, at most, only traces. There is no analogy between oil-sands and oil-shales, a fact not generally appreciated except by persons familiar with both types of rock. No oil is extractable from oil-shale by any mechanical or chemical process unless it be accompanied by the application of heat. There are, in oil-shale, microscopic substances residual from animal and plant life, and these when subjected to heat will create liquid hydro-carbons, which while nascent and under the influence of the same thermal conditions, will vaporize, the latter reaction being precisely the same as occurs when petroleum is refined in a still. The condensation of the vapor produces oil.

Oil-shales, like other shales, are sedimentary in origin. They were laid down as muddy deposits in shallow seas and the remains of organic life were disseminated in them. Such deposits were originally horizontal. In the Rocky Mountain region of Utah-Colorado-Wyoming, the shales have remained almost in this position, but in many regions they have been uptilted, warped, folded, and distorted just as have been rocks of all ages and modes of origin.

Beds of bituminous shale may range in thickness up to hundreds of feet. Bituminous and non-bituminous shales frequently intermingle and blend into one another along continuous strata. They also alternate in layers. The grade of shale depends wholly upon the amount of organic remains—the so-called 'kerogen' disseminated through it. A shale will vary in richness in this way from barren rock up to material of high value as gauged by the economically possible eduction of oil therefrom. It is the custom to speak of the grade of a shale in gallons per ton; a shale is of average grade if it can be made to yield one barrel, or 42 gallons, per ton. There are vast deposits that will yield this quantity of total oil upon ordinary distillation, whereas there are deposits of considerable size that will render twice this amount and even more. In the shale districts it is customary to plan the handling of rock that will produce at least one barrel of oil per ton.

Oil-shales are of several varieties, readily identified by persons familiar with such rocks. There are massive, papery paraffin, asphaltic, sandy, and limey. Each has its peculiar texture and behaves distinctively when subjected to heat or when undergoing pulverization. There is considerable range in the color of oil-shales, this ranging from deep black through all shades of brown and blue to a light gray. I know of at least one deposit the outcrop of which is a light yellow resembling ochre.

Property Rights. In most of our Western States shale-land is public domain. Thus far it has been located as placer claims, although there have never been any legislative or Land-Office regulations specifically applicable to land of this character. Oil-placer locations do not strictly apply for the reason explained, namely, that the land is not technically oil-bearing. Nevertheless, lacking a more appropriate method of filing, all claims have been located precisely as though they were on oil-land.

When, in 1916, it became certain that the public would soon take notice of oil-shale, prospectors filed upon tracts that would attract early attention from investors. The first official investigation of the Green River field (the principal district of the Utah-Colorado-Wyoming region) was made in 1913 by E. G. Woodruff and David T. Day of the U. S. Geological Survey. The bulletin covering the field work was published in 1914. The second investigation was by Dean Winchester, also of the U. S. Geological Survey, in 1916. By the end of 1917 practically all of the best land relatively close to a railroad had been located. This does not mean, by any means, that available land of good quality is scarce nor difficult to secure; this one field is of such vast extent that figures as to total acreage, even as to the number of square miles, mean but little. There is plenty of land for all comers. Land that has been carefully located is purchasable at reasonable prices.

Since the beginning of the movement to enact a Federal leasing bill for oil-lands, there has been uneasiness as to the validity of shale-land locations filed subsequent to December 3, 1917. Very few new claims were located last year. The bill failed to pass during the recent session of Congress and the status of oil-shale land remains doubtful. For that reason current transactions are restricted to such properties as were validly located prior to the end of 1917. Should a leasing bill be passed hereafter it will have little effect on the industry as land-rights would then be leaseholds from Uncle Sam at a nominal rental of 50 cents per acre per year. Single placer claims are of 160 acres each. Upon each such claim there must now be expended an annual assessment, in the nature of labor and improvements, amounting to $100. Under the leasing arrangement this annual expense would be only $80. All transfers of ownership thus far have been by the giving of miner's quit-claim deeds. Very few oil-shale properties in the West have been patented, that is, purchased from the Government.

Mining Problems. The future of this industry depends wholly upon success in recovering the valuable hydrocarbons. I have not dwelt upon the possibilities of manufacturing by-products from oil-shale. I believe that profits can be measurably augmented by making such products as ammonium sulphate and crude potash, but I feel that the chief attraction of these shales, in the immediate future, is their potential yield of oils and greases. I recommend the erection of simple plants at first and the recovery of a few simple products. When the manufacture of these products has been stabilized, it will be time to attempt the by-product end of the industry.

No doubt exists regarding vastness of resources. To date, the main problem has been to devise apparatus that will efficiently and systematically handle large amounts of shale. The matter is found to resolve itself into an industrial enterprise involving mining as the business that provides the raw material.

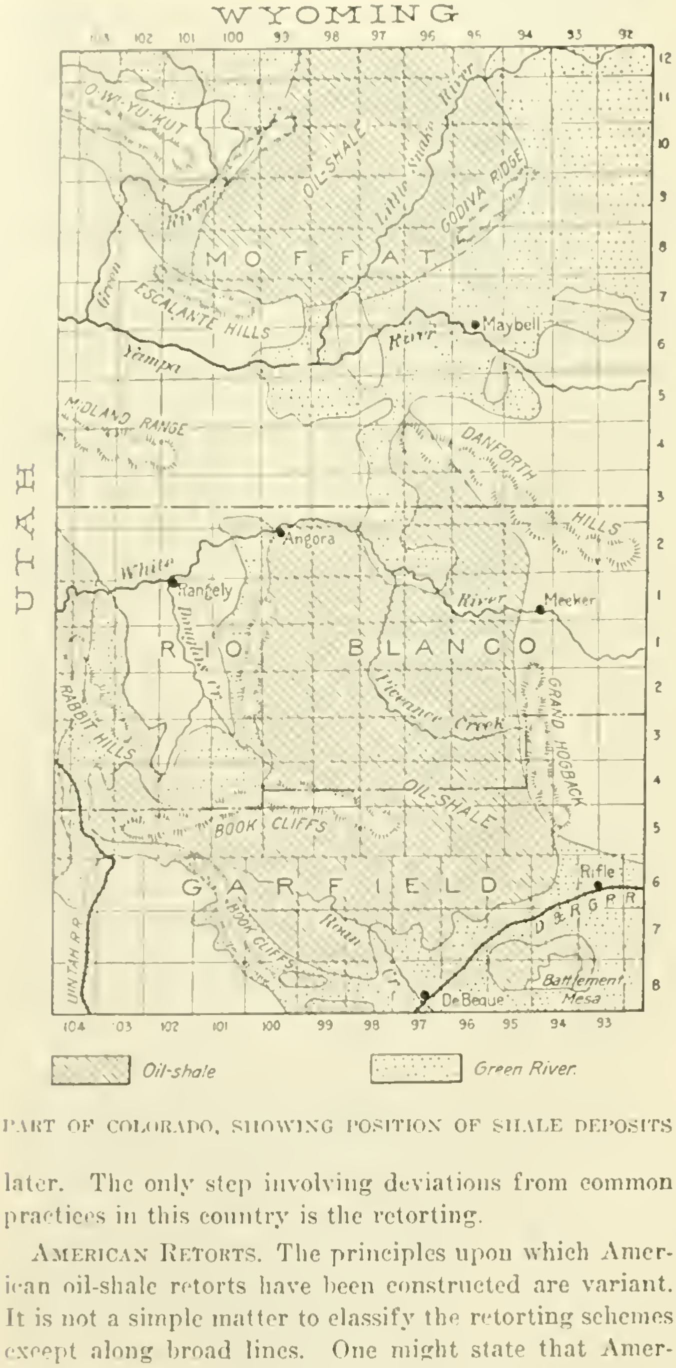
The mining of shale will introduce numerous interesting problems, no doubt. In a few instances it will be found practicable to excavate oil-shale by open-pit systems, but most of the shale beds must be mined underground by methods which will probably closely imitate those practiced in coal mining. Shale beds standing at steep dips will be excavated by overhead stoping methods. The Colorado-Utah-Wyoming oil-shale beds lie practically flat. When these beds cap the hills or constitute the uppermost formation in low districts, the shale may be handled with power-shovels. In many localities, however, the beds outcrop as steep cliffs and their excavation must be accomplished by driving entries and rooms. Engineers will probably evolve new methods of mining. It may be found, as underground workings are extended considerable distances, that mechanical means for ventilation will be required.

In the region around DeBeque and Grand Valley, in Colorado, it is proposed to exploit beds lying hundreds, even thousands, of feet above the sites for mills; therefore aerial tramways are planned for transporting the shale from mine to mill. One company will erect its plant several hundreds of feet below its thick ledge of shale. The mined material will be dropped over a perpendicular cliff for about half the distance and is expected to roll down a steep talus slope the remainder of the descent.

Crushing. Before being charged into retorts, raw shale must be crushed, the fineness differing according to the demands of the inventors of retorts. Some retorts are expected to work with shale broken into chunks roughly corresponding to 'egg' size in coal; other retorts are intended to handle the shale crushed to half-inch, quarter-inch, and 8-mesh; one or two processes require pulverization of the feed.

Some varieties of oil-shale may be crushed and ground as readily and with the same kinds of machines that are applied to brick-shales. However, massive shale that is unusually rich in oil-producing substances is refractory during grinding in the sense that it resists fracture because of its rather tough structure, and it becomes still tougher and even plastic under the influence of the heat generated in certain types of crushers. For this reason it is impossible to work certain oil-shales through jaw-crushers. In crushers that are completely housed or in which the grinding-chamber is itself a closed affair, the comminution of such rich shale creates sufficient heat to not only make the rock pasty but to cause vapors that form explosive mixtures with air. But, on the whole, the grinding of mine-run shale is not a serious problem, it being simply a matter of experimentation with various types of crushers, followed by intelligent selection.

The manufacture of shale-oil is not, as some persons have been led to believe, a formidable process, nor does it require an expensive plant. A typical shale-mill will have ample bins for mine-run storage, suitable crushing apparatus, a battery of retorts, simple air-cooled condensing pipes, means for separating the liquids from the non-condensible gases, a scrubber for such gases to recover ammonia and gas-tar, and tankage for all products. Additional apparatus for refining will be mentioned later. The only step involving deviations from common practices in this country is the retorting.



PART OF COLORADO, SHOWING POSITION OF SHALE DEPOSITS

American Retorts. The principles upon which American oil-shale retorts have been constructed are variant. It is not a simple matter to classify the retorting schemes except along broad lines. One might state that American retorts belong to the following two divisions: internally fired and externally fired.

Under this classification the majority of processes would fall into the second class, for most inventors cling to the belief that the removal of the vapor should be performed in an atmosphere destitute of oxygen and gases of combustion. The Chew process is an example of internal firing. Shale is fed continuously into the top of a vertical cylindrical chamber the bottom of which is a slowly rotating grate upon which is maintained a fire of the lower 12 or more inches of the shale itself. The gases of combustion are drawn upward through the charge, imparting thermal units to the cooler fragments of shale and thereby generating an oil-vapor that passes from the retort at the top and thence through a water-cooled condensing apparatus.

The retorts that are fired externally may be subdivided as follows: those that distil vapor in their own atmosphere; those injecting live steam; and those introducing inert fixed gas from previous distillation. In the first type belong most of the recent retorts. They maintain a slight internal pressure caused by vaporization of water and nascent hydrocarbons, and this pressure causes the steady expulsion of vapor into the condensing system.

The introduction of steam has been proposed by some inventors to contribute thermal units to the shale charge, to increase the yield of ammonia, and to create a higher pressure in order to more vigorously expel the vapor. The opinion is advanced by a few authorities that the addition of live steam will prevent caking of the shale. All oil-shale carries natural moisture, as well as the water of physical structure, so that any retort will contain a relatively moist atmosphere. No matter how dry a charge of oil-shale may be apparently when charged into a retort, a considerable quantity of water will be recovered at the condenser.

The idea of returning non-condesible gases into the retort has merit. The Pritchard process will pre-heat such gas by conveying it through a coil of pipe in the waste-gas flue of the furnace. The gas will then enter the top of the retort and will filter its way down through the charge of shale. In this scheme there will be not only a conservation of fuel but the saved heat will be systematically distributed throughout the mass of shale within the retort. This added gas, blended with the newly-generated vapor and gas, is finally withdrawn from the bottom of the retort, the continually augmenting volume of fixed gas being accommodated by a gasometer.

Some retorts are designed to conduct their reactions in a rarified atmosphere maintained by a rapid withdrawal of the vapor into condensing apparatus under an incomplete vacuum. Others work under induced pressure, which may be produced by constriction of the vapor exits, by the introduction of live steam (as previously mentioned), or by the simple scheme of spraying water upon the heated charge of shale. Most processes, however, will create vapor at practically the atmospheric pressure, the exits being of ample area.

An obvious classification of oil-shale processes would separate them into those that operate intermittently and those that are charged and discharged continuously. Between these extremes we find schemes for an intermediate procedure. In the Fuller process this is accomplished by building the vertical retort in two sections. In the upper section the shale is heated sufficiently to distill its aqueous contents, when it is dropped through a trap-door or valve into the lower chamber to receive its ultimate distillation. When the upper chamber has been emptied it is immediately recharged with fresh shale, so that distillation is carried on practically continuously.

The Wallace retort, adopted by the Ute Oil Co. for operation in the Watson field, in Utah, is an upright cast-iron cylinder of 40 in. diameter and 10 ft. high. Placed centrally within this is a large vertical cast-iron tube having many perforations. The prepared raw shale is charged intermittently into the annular space between the two iron cylinders and heat is applied from without, the temperature being slowly raised to 1000°F. All vapors find egress through the central column and, blending together, are withdrawn from the retort to the condensing apparatus under slightly diminished pressure.

To satisfy the requirements of prospective purchasers of oil-shale equipment, numerous inventors have endeavored to obtain absolute continuity in the retorting process. This has led to adaptations of the mechanical principles involved in screw-conveyors, in raking and scraping types of ore-classifiers and in multiple-deck revolving ore-roasters. It is proposed to adapt coal-distillation schemes to the treatment of oil-shale. Among the processes devised to use scraping mechanisms may be mentioned the Beam and the Young. The Del Monte is one process that will force the shale continuously through an almost level retort by means of a spiral conveyor. The Green-Laucks will use the same mechanism in a vertical retort. The Wingett retort has multiple decks and plows somewhat similar to those in a MacDougal roaster. Alternating with the decks upon which the shale is heated are chambers within which heat is generated by jets for burning gaseous or liquid fuels.

FRACTIONATION PROCESSES. Shale processes may be classified into those that deliver a single oily product and those that deliver two or more fractions of the total oil. Perhaps the best known of the second sort is the new Galloupe, the mechanism of which is peculiar to itself. An outer, stationary, cast-iron vertical shell is provided with inwardly projecting narrow shelves arranged very much like winding stairways. Within this there slowly rotates a smaller cast-iron cylindrical shell outwardly provided with similar shelves so set as to pass between the shelves of the fixed shell. The shale, which is fed continuously into the top of this retort, works its way spirally down these shelves and is discharged at the bottom. Heated gases from the furnace pass upward through the inner shell as well as completely around the outer shell. As the shale descends from shelf to shelf it encounters successively hotter zones and simultaneously yields vapors of increasing density. These vapors promptly pass into condensing pipes, each such pipe delivering a distinct fraction.

LOOKING UP COON CREEK, IN GARFIELD COUNTY, COLORADO. CENTRAL MOUNTAIN IS THE PROPERTY OF THE AMERICAN SHALE & REFINING CO.

Practically the same theory is followed in all fractionating continuous processes. The shale is heated gradually and the resulting vapors are withdrawn before they can commingle with vapors of higher or lower densities. It is not expected that this sort of fractionation directly from the shale will be perfect, for it is inevitable that each such fraction will be more or less blended with vapors from adjacent higher and lower thermal zones of the retort. However, it is believed that, after any such retort has been in commission long enough to permit close adjustments of temperature and shale feed, the fraction delivered from each take-off will be fairly constant in quality.

TYPES OF RETORTS. Having now sketched a few salient features of recent shale retorts, we might wish to decide what description best fits each one of the many processes. Taking them up in this fashion, we shall find that almost no two of them may be similarly classified in all particulars. It would appear that all possible combinations have been contrived into individual retorts and one finds an interesting field before him in studying the technology of oil-shale distillation.
